THE eleventh annual report of the Department of Scientific and Industrial Research, New Zealand, covers the year 1936–37, and, in addition to the secretary's report and the reports of the research committees of the Council, includes the reports of the Dominion Laboratory, the Geological Survey Branch, the Meteorological Branch and the Dominion, Apia and Magnetic Observatories. The Minister's covering statement refers to the establishment of a Bureau of Social Science Research, the work of which will include the co-ordination of the activities of research bodies or individuals in this field and the undertaking of investigations to assist the Government by providing the factual bases for social policy measures. Outstanding developments of the year were the reorganization of plant research under the Plant Research Bureau and the steps taken to establish an Animal Research Bureau. The Plant Diseases Division of the former Bureau has made good progress in the study of virus diseases of farm crops, particularly tobacco, and has also completed comparative trials of new organic mercury dusts. Diseases of tomatoes and potatoes, etc., have also been investigated, and the Entomological Division of the Bureau has obtained satisfactory results in the biological control of the white butterfly, although new lines of attack for the control of the diamond black moth have been necessary. The Dairy Research Institute has made further progress in its study of the control of gas-producing organisms which cause openness in cheese, and has continued its studies of the elimination of the feed taint in butter and cream from certain districts.

THE Wheat Research Institute has continued to expand its long-range work on wheat breeding, while the Leather Research Laboratory has given special attention to methods of assessing the quality of leather as a guide to improvements. A particular group of chemical constituents has been studied in relation to the wearing-value of leather. An extensive programme of fruit research has included an attack on the problem of the mouldy core of apples and the control of internal cork of apples, while the soil and land utilization survey has been continued to give a fairly complete picture of the agricultural resources of the Hawke's Bay province. Other features of the year have been the establishment of the Standards Institute, which has already done much to promote the adoption of standards and establish committees and sub-committees covering a wide range of subjects. Evidence is already available of the benefits of this work to the Dominion. Research associations have been developed during the year in connexion with the tobacco, wool manufacturing and footwear manufacturing industries, and a feature of staff appointments during the year has been the recruitment of New Zealand science graduates who had migrated overseas. Of the total expenditure of £131,957 of the Department, £71,233 is on research investigations, £13,268 of which is derived from industries and £13,243 from sales and miscellaneous recoveries. Expenditure on the Dominion Laboratory was £17,261 and on the Meteorological Office £12,069.

The Ontario Research Foundation

THE report of the Ontario Research Foundation for 1936 refers to the increased work carried out for industry. Two new laboratories for research on paints and on air-conditioning are now running smoothly. In the former, investigations on weathering tests and chemical analysis of white house paints, weathering of structural metal paints, etc., are in progress, while the latter is investigating the 'summer' comfort requirements in regard to temperature and humidity of people in Toronto. The work of the Textiles Division has been concerned with the development of a textile oil for use in processing woollen materials as well as with the development of a process for high-resistance tusser silk for electrical insulation purposes, and with processes for the reduction of shrinkage in textile materials. The Division of Engineering and Metallurgy has continued its studies on the effect of heat treatment on chilled cast-iron and on the forgeability of metals. The Division of Biochemistry has been concerned with the development of a new system of combination vegetable tannage for sale and transmission belting leather. A microscopic method for the early diagnosis of bovine mastitis has been worked out by the Division of Pathology and Bacteriology, while other work of the Foundation has been concerned with the deodorization and partial hydrogenation of cod liver oil without destroying the vitamin content, with the incidence of diseases of apples and related problems, and with a process for transferring pigments used in the paint industry from aqueous pastes to the oil phase.

Desiccation in Africa

A supplement to the *Journal of the Royal African Society* of January entitled "The Man-made Desert in Africa: Erosion and Drought" by Prof. E. P. Stebbing offers yet another warning that in many parts of the world drifting sand and eroding soil are beginning seriously to clog the wheels of administrative machinery. Erosion is a matter in which African Governments interfere unwillingly, for effective control often means uprooting social, agricultural and religious customs upon which tribal life, which British Governments strive to preserve, is based. In this paper, Stebbing regards erosion primarily from the point of view of its effect on water supplies, and believes that with increasing erosion, a falling water-table and decreasing water supplies, the character of the rainfall deteriorates, wet years becoming less, and droughts more frequent, and of longer duration. When deterioration has reached what Stebbing terms the "intermittent rainfall stage", where continuous agriculture is scarcely feasible, man has his last chance to change his methods and prevent the final encroachment of the desert. Much of Africa seems to have entered upon this critical stage of deterioration, and some parts have passed it irrevocably. Stebbing emphasizes that now "it is for the Administration to act". The immediate needs for Africa's conservation are more money and more officers trained to the work. Given these, administrations might put into operation soil conservation programmes which, if carried out, would turn the scales, at or before the intermittent rainfall stage, against the desert's encroachment. The trouble is that we cannot tell, until we have tried them out, whether plans for soil conservation are compatible with plans for the harmonious social development of whites and blacks.

Grass Seed Production

Three new bulletins have been issued in the Herbage Publication Series by the Imperial Bureau of Plant Genetics, Aberystwyth. Bulletin 19, "Production of Grass Seed" (price 5*s*.), is edited by R. O. Whyte and consists of an international exchange of opinions and experiences on the technique of producing seed of graminaceous herbage and forage plants. The countries represented are Scotland, Northern Ireland, New Zealand, the United States, Germany and Sweden, the names and addresses of the contributors being supplied in each case. Bulletin 20, "Insect and other Pests injurious to the Production of Seed in Herbage and Forage Crops" (price 2*s*. 6*d*.), has been prepared by H. F. Barnes. This paper is essentially a summary of the available information concerning some of these pests, but although growers should find this most useful, they are nevertheless advised to consult the advisory entomologist in their particular area as to the best method for safeguarding their crops, as it is impossible to secure really satisfactory results without due attention to local conditions. Bulletin 21, "The Influence of Climatic Conditions on Type Composition", by Nils Sylvén (price 1*s*.), gives an account of experiments in Sweden on the changes induced in herbage plants grown for seed outside their proper growing districts. It is evident that there is considerable danger of loss of valuable characters if this process is continued. For satisfactory results, seed must be obtained direct from the breeding station or its vicinity, and care taken to keep seed from the original source scrupulously apart from that grown in a different locality, or much of the value of the selection work will be lost.

Education in the Indian Villages

A paper by Capt. J. W. Petavel before the Economics Society of Osmania University on September 24 last year emphasizes the value of educative employment in the economic system of the Indian village, and particularly that of the educational colony in Indian rural education. One of the greatest possibilities to be explored, however, is that of the use of educational colonies for town children and adolescents, and these should be for the benefit of poor middle-class people as well as for the working classes and should include secondary as well as primary education. Stress is laid in this system on productive work, and the scheme of factory colonies outlined is also advocated as a contribution to improved world relations. Both in the rural and in the factory colonies one of the primary needs is the co-operation of scientific men and other professional workers in leadership and on a part-time basis in teaching and other capacities. Moreover, the colony organization offers one of the best opportunities of dealing with India's root problem of increasing the productivity of the land to yield more food for her growing population. The establishment of a standing committee for unemployment and poverty problems, to plan and assist research in the directions indicated by the success of the Swiss labour colony of Witzwil, is also urged.

Report of the University of Leeds

The University of Leeds report for 1936–37 records as the outstanding event of the year a gift of £200,000 by Mr. Frank Parkinson. It is significant that the report gives prominence to Mr. Parkinson's expressed belief "that the university can render the highest service to the community by keeping the realities of life and the need of breadth of vision in human affairs before its students" and refers to an expression of the same belief by Lord Nuffield. Among other endowments were an anonymous gift of £20,000 and a legacy of £25,000 for founding a chair of psychology. The subject of employment of graduates is dealt with at greater length than is usual in these annual reports. In the technological departments, no difficulty was found in obtaining employment immediately after, and even before, graduation, To meet the situation created by the time-lag between graduation and employment in the teaching profession the Appointments Board exerted itself to find temporary summer employments. The usefulness of this Board is said to have greatly increased during the last few years, the number of vacant appointments notified to it having risen from 380 in 1932 to 3,500 in 1937. Appreciative reference is made to the report on employment of graduates published by the National Union of Students. Schemes for medical examination of students at their own option and for physical instruction were under consideration during the year and are now in process of realization.

Quantitative Economics

IN a paper on econometric researches, appearing in the series of publications dealing with economic problems edited by Dr. R. Gilrat (No. 412; Hermann and Cie., 6 Rue de la Sorbonne, 6, Paris, 1936), Prof. R. Ray deals with the demand for goods for direct consumption. Results obtained in this question of demand, whether by experimental methods or by the application of statistical methods to observations, afford a strong presumption in favour of the quantitative investigation of economic phenomena. Prof. Ray discusses the theories of Cournot, Dupint and Marshall, who considered demands as the function of a single variable, as well as the theories of Walras and the mathematical school. His own investigations on products for direct consumption suggest that for certain products or services, coefficients of elasticity can be used to characterize the demand. In considering the elasticity of demand, it is essential to analyse the part which the law of substitution plays, and accordingly it is desirable to limit the investigations to products which lend themselves less readily than others to substitution, or to investigate a group of products which are readily substituted one for another in meeting the same need. The method of multiple correlation offers interesting possibilities, and Prof. Ray concludes that the demand for goods or services investigated so far is nearly always inelastic.

Effects of Dry Rot in Ships

THE presidential address of Dr. John Ramsbottom to the Essex Field Club dealt with dry rot in ships. Its text appears in the *Essex Naturalist* (25, 231; 1937), and provides an interesting account of the struggle of naval builders with wood-rotting fungi. A historical survey from the sixteenth century onwards traces the use of various kinds and qualities of timber, and shows how prone they were to rotting within the vessel, and above the water-line. The diarist Pepys made some contributions towards an understanding of the problem, but it was largely the work of James Sowerby, the author of "English Fungi", which first directed attention to the real cause. He figured twenty-three species of "Fungi found in the Dockyards and Ships of Great Britain from Deptford to Plymouth 1812". *Merulius lachrymans* was included in the list, and there can be little doubt that it was one of the chief agents of decay. Many substances were used to impregnate timber in an effort to control the rot; but it was not until the appearance of ironclad ships that dry rot ceased to trouble the Royal Navy.

The Rabbit Problem

IN certain localities, as is well known, the prevalence of rabbits has become of some importance in horticulture, agriculture and forestry. In order to deal with this nuisance effectively and humanely, the University of London Animal Welfare Society (ULAWS) has published a pamphlet, entitled "Instructions for Dealing with Rabbits", compiled by Capt. C. W. Hume, in which the chief methods of rabbit destruction are fully described. In addition, a list of some relatively rabbit-proof plants and details of rabbit-proof fencing are given. Sir Frederick Hobday, in a foreword, commends the pamphlet, a copy of which will be sent free on receipt of a stamped envelope measuring 6 in. by 9 in. by ULAWS, 42 Torrington Square, London, W.C.1.

Cambridge Dissertations for Degrees

A BOOK of "Abstracts of Dissertations approved for the Ph.D., M.Sc. and M.Litt. Degrees in the University of Cambridge" during the academic year 1936–37 has been issued (Published by Authority: The University Press, Cambridge, 1937.) Each summary has been approved by the examiners or by the student's supervisor, and gives a good idea of the matter of a dissertation. Copies of the dissertations are deposited in the University Library (Ph.D. degrees) or in the University Registry (M.Sc. and M.Litt. degrees).

Reference Standards Laboratory

AFTER a delay of many years, the establishment of a laboratory for the maintenance in Australia of standards of length, mass, electrical units, etc., has been approved by the Commonwealth Government. It will probably be placed at Canberra, the estimated cost of the building being £80,000. The administration will be in the hands of the Council for Scientific and Industrial Research, which will maintain intimate contact with the National Physical Laboratory at Teddington in general accordance with a plan drawn up some ten years ago.

National Academy of the Lincei

A SUPPLEMENTARY number of the *Atti della Reale Accademia Nazionale dei Lincei* (1937) contains an account of the formal annual meeting held in Rome on June 6, 1937, in the presence of H.M. the King of Italy, to whom tribute was also paid for the first time as Emperor of Abyssinia. Among the chief awards announced by the President, V. Rossi, are those of the Bocconi Prize for cancer research to Prof. F. Pentimalli and the Cannizzaro Prize in chemistry to Prof. L. Ruzicka, Zurich. The following were elected as members during the preceding year: A. Ghigi, D. de Blasi, P. G. Goidanich, L. Castiglioni, P. Ducati, A. Maiuri, P. de Francisci, F. Flora, as national members, and A. Carrelli, G. Polvani, F. Ercole, as corresponding members. The centenary of the death of the Italian poet, Giacomo Leopardi, was commemorated by an address given by G. Gentile.

Royal Academy of Belgium: Prize Awards

The following prize awards have been announced by the Royal Academy of Belgium: the Théophile Cluge Prize to Dr. J. J. Bouckaert for his work on physiology; the Agathon De Potter Prize for astronomy to S. Arend, for mathematics to F. Bureau, for physics to J. Géhéniau, for chemistry to Prof. W. Mund, for mineralogy to E. Polinard, for biology to Z. M. Bacq and to L. Lison; the Schepkens Prize to J. Beirnaert for his work on genetics and the improvement of the oil palm; the Wetrems Prize to L. Coppens for his work on fire-damp.

Announcements

Dr. L. J. Spencer, formerly keeper of minerals in the British Museum (Natural History), has been elected a corresponding member of the American Museum of Natural History, New York.

At the general meeting at Indianapolis of the American Society of Plant Physiologists, Prof. Henry H. Dixon, of Trinity College, Dublin, was elected an honorary corresponding member of the Society.

Sir Walter Langdon-Brown and Prof. W. J. Dilling have been nominated by the Privy Council members of the council of the Pharmaceutical Society of Great Britain, in succession to Sir Humphry Rolleston and Prof. J. A. Gunn, who have retired. Sir Malcolm Delevingne will continue as the third member nominated by the Privy Council.

A committee has been appointed under the chairmanship of Mr. John Forster with two representatives of the Medical Research Council, Sir David Munro and Mr. Bradford Hill, two representatives of the London Passenger Transport Board, and two representatives of the Transport and General Workers Union to investigate the conditions of work and their effect on health of the London omnibus workers.

At the annual general meeting of the Ray Society on March 24 the following officers were re-elected: *President*, Sir Sidney F. Harmer; *Treasurer*, Prof. F. E. Weiss; *Secretary*, Dr. W. T. Calman. Prof. F. Balfour-Browne was elected a vice-president, and Dr. J. Ramsbottom and Mr. J. L. Chaworth-Musters new members of the council. It was announced that a translation by the late Sir Arthur Hort of the "Critica Botanica" of Linnæus will shortly be published and that among other works in preparation is one on the distribution and ecology of British spiders by Dr. W. S. Bristowe.

Dr. Heinrich von Fischer, professor of meteorology at Vienna, has been made an honorary member of the German Meteorological Society and has been awarded the Silver Hillmann Medal by the Air Minister of the Reich.

The twenty-fourth Annual Conference of the National Association for the Prevention of Tuberculosis will be held at the British Medical Association House, Tavistock Square, W.C.1, on June 30–July 2.

The Royal Sanitary Institute will hold a further course of instruction in disinfestation of houses and furniture from the bed-bug, beginning on May 16. Further information can be obtained from the Secretary, 90 Buckingham Palace Road, S.W.1.

The All-India Population and Family Hygiene Conference will be held at Bombay on April 16–19 instead of in January as originally announced. Further information can be obtained from the Honorary Secretary, 8 Ormiston Road, Apollo Bunder, Bombay.

The third International Congress for Microbiology will be held at the Waldorf-Astoria Hotel, New York City, on September 2–9, 1939, under the auspices of the International Association of Microbiologists and the presidency of Dr. T. M. Rivers, Rockefeller Institute for Medical Research, New York. Further information can be obtained from the General Secretary, Dr. M. H. Dawson, College of Physicians and Surgeons, 620 West 168th Street, New York, or from Dr. R. St. John-Brooks, Lister Institute, Chelsea Bridge Road, London, S.W.1.

The International Federation for Documentation will hold its fourteenth International Conference on Documentation under the presidency of Sir William Bragg at Lady Margaret Hall, Oxford, on September 21–25. Members of the Conference will visit the Science Museum, London, on September 26. Advantage will be taken of the meeting being in England to hold joint sessions on the mornings of September 24–25 with the Association of Special Libraries and Information Bureaux. Further information can be obtained from the Secretary, Miss M. Gosset, The Science Library, South Kensington, London, S.W.7.

Gustav Fock, Leipzig, has issued an important catalogue listing close on 4,000 items, of which, in addition to journals and works of general zoology, the most extensive series deal with the physiology and biology of animals, psychology, zoogeography, and animals of economic importance. From Antiquariaat Junk, Den Haag (Holland), comes a list of 2,014 items concerning the one group Vermes.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

Notes on points in some of this week's letters appear on p. 650.

Correspondents are invited to attach similar summaries to their communications.

Resonance Transmutations of Carbon by Protons

During the investigation of the capture radiation of light elements bombarded by protons, we have found for carbon the following results. The intensity of capture radiation was measured for different proton energies by the number of coincidences produced in a pair of Geiger-Muller counters. The coincidences were caused by electrons released from an aluminium plate by the incident γ-radiation. The quantum energy of this radiation was determined by finding the range of the electrons in millimetres of aluminium absorber placed between the counters. The intensity of γ-ray emission at different bombarding voltages is shown by Curve 1 of Fig. 1. Two resonances are clearly observed at 400 and 500 kv. approximately. With a bombarding proton energy of 560 kv., corresponding to the second peak of this curve, we find the γ-ray energy to be 7·4 Mv., as deduced from the end-point at 11 mm. of aluminium (Curve 1, Fig. 2). This is in marked disagreement with the value of the γ-ray energy to be expected from the reaction

$$^{12}C + {}^{1}H = {}^{13}N + h\nu \quad . \quad . \quad . \quad . \quad (1)$$

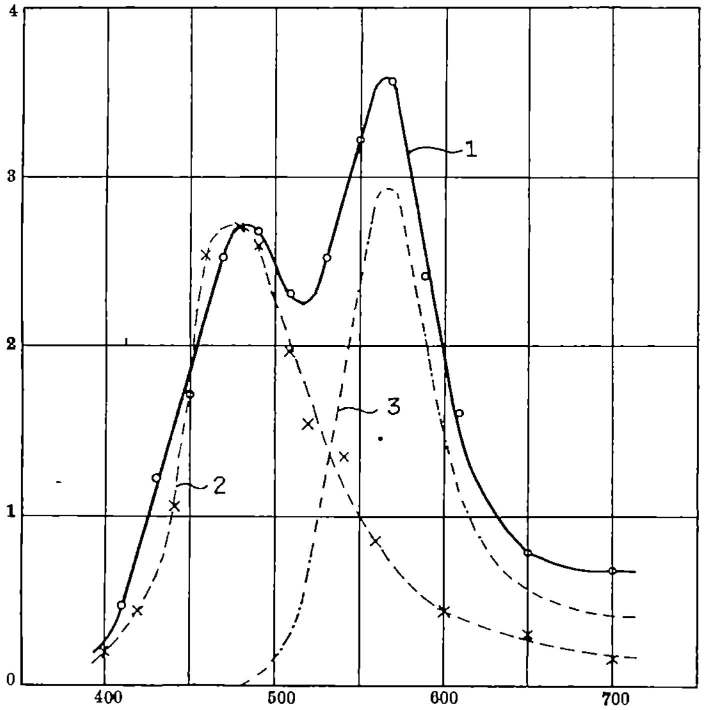

Fig. 1.

Resonance curves for ^{12}C and ^{13}C.

However, if we consider the reaction

$$^{13}C + {}^{1}H = {}^{14}N + h\nu, \quad . \quad . \quad . \quad . \quad (2)$$

it is found by calculation, using accepted mass values and taking into account the energy of the incident protons, that the γ-ray energy is 8·2 Mv. for this process. This reaction has not previously been observed, and the following experiments confirm that the resonance peak of Fig. 1 at 560 kv. must be ascribed to the rarer isotope ^{13}C and not to ^{12}C.

The quantum energy of the capture γ-radiation was again measured with the energy of the incident protons changed from 560 kv. to 470 kv. Curve 2 of Fig. 2 shows the new absorption measurements in aluminium, and the γ-ray energy deduced is 2·6 Mv. For comparison the absorption measurements obtained under the same conditions with the γ-rays of thorium C″ are shown by the crosses of Fig. 2. Using the accepted mass values in equation (1), we find that for protons of energy 470 kv. the γ-ray emitted should have an energy of 2·37 Mv., in good agreement with our experimental value of 2·6 Mv. The above results suggest that the peak in the γ-ray excitation curve at 470 kv. must be attributed to the formation of the radioactive ^{13}N, whilst the peak at 560 kv. must be attributed to the formation of stable ^{14}N.

It is strange to notice that Hafstad and Tuve[1], in a measurement of the amount of radioactivity excited at different proton energies, obtained some evidence for two resonances at 400 kv. and 480 kv. The association, however, of the two resonances found by these workers with the resonances which we find in the capture γ-excitation is not possible on account of the above measurements of the energies of the γ-rays and our proposed interpretation. In view of this coincidence, however, we have repeated Hafstad and Tuve's measurements of the excitation of radioactivity at different proton energies. Our results, shown in Curve 2 of Fig. 1, give no evidence of the second resonance found by Hafstad and Tuve. This curve for ^{12}C was obtained by bombarding the same target with protons for a fixed interval of time and measuring the subsequent positron emission with a thin-walled Geiger-Müller counter. It has been reduced to make the best fit to Curve 1 for the capture γ-radiation. We note that only the first peak at 470 kv. in the γ-ray excitation curve can be associated with the radioactivity. The ^{13}C resonance curve can be found by subtracting Curve 2 from Curve 1 and is shown as Curve 3 of Fig. 1, with a threshold value for resonance at about 500 kv. It is interesting to note that ^{13}C has such a large cross-section for proton capture that its yield is of the same order as that of ^{12}C, though it is about 1 per cent abundant in natural carbon.

The λ-Phenomenon of Liquid Helium and the Bose-Einstein Degeneracy

In a recent paper[1] Fröhlich has tried to interpret the λ-phenomenon of liquid helium as an order–disorder transition between n holes and n helium atoms in a body-centred cubic lattice of $2n$ places. He remarks that a body-centred cubic lattice may be considered as consisting of two shifted diamond lattices, and he assumes that below the λ-point the helium atoms prefer the places of one of the two diamond lattices. The transition is treated on the lines of the Bragg-Williams-Bethe theory as a phase transition of second order in close analogy to the transition observed with β-brass. Jones and Allen in a recent communication to Nature[2] also referred to this idea. In both these papers, use is made of the fact, established by the present author, that with the absorbed abnormally great molecular volume of liquid helium (caused by the zero motion[3]) the diamond-configuration has the lowest potential energy among all regular lattice structures[4].

In this note, I should like first to show that the mechanism proposed by Fröhlich cannot be maintained and then to direct attention to an entirely different interpretation of this strange phenomenon.

(1) According to Frohlich, a diamond lattice of He atoms, when partly formed, should offer, to any other He atom, a preference for being attached at those points which belong to the same diamond lattice, that is, the binding energy at a diamond point should be greater than anywhere else. It is, however, easy to see that just those points, which according to Fröhlich should become less favoured for low temperatures, have an appreciably greater binding energy. It is true these holes have four nearest neighbours at exactly the same distance (3·08 A.), as the lattice points of the diamond lattice have, but in addition they possess six second neighbours at the distance of 3·57 A. which the diamond lattice points do not possess, and these second neighbours contribute considerably to the binding energy just at the hole-places (about 50 per cent to the potential energy). Therefore, actually no such co-operative phenomenon will appear as supposed by Fröhlich. The atoms would rather frequent the holes as much as the proper diamond lattice points, and this would signify that we have a body-centred lattice of $2n$ places for n atoms, every place being occupied with the probability $\frac{1}{2}$ only—even at the absolute zero. In this configuration every atom has on the average four nearest neighbours at a distance of 3·08 A., as in the diamond configuration, but in addition there are here on the average three second neighbours at the distance of 3·57 A. In the diamond lattice there are twelve second neighbours but at a distance of 5·04 A., where there is almost no Van der Waals field. It might be mentioned, by the way, that a face-centred lattice of $2n$ places for n atoms (on the average 6 first neighbours at a distance of 3·17 A.) has been found to have a still little lower energy than the configuration just discussed of the co-ordination number 4.

Complete numerical details cannot be given here ; in any event it can be shown by such energetic discussions that a static spatial model of liquid He II of whatever regular configuration is certainly not possible. This has been previously suggested in consideration of the great zero point amplitude calculated for He[4]. The determination of the most favourable co-ordination numbers of the first and second neighbours, however, maintains a good physical meaning : it may be considered as a rough Hartree calculus which yields the self-consistent field and the corresponding probability distribution of the atoms belonging to the minimum of energy.

(2) It seems, therefore, reasonable to imagine a model in which each He atom moves in a self-consistent periodic field formed by the other atoms. The different states of the atoms may be described by eigen functions of a similar type to the electronic eigen functions which appear in Bloch's theory of metals ; and, as in Bloch's theory, the energy of the lowest states will roughly be represented by a quadratic function of the wave number K,

$$E = \frac{\hbar^2}{2m^*} K^2,$$

the effective mass m^* being of the order of magnitude of the mass of the atoms. But in the present case we are obliged to apply Bose-Einstein statistics instead of Fermi statistics.

(3) In his well-known papers, Einstein has already discussed a peculiar condensation phenomenon of the 'Bose-Einstein' gas; but in the course of time the degeneracy of the Bose-Einstein gas has rather got the reputation of having only a purely imaginary existence. Thus it is perhaps not generally known that this condensation phenomenon actually represents a discontinuity of the derivative of the specific heat (phase transition of third order). In the accompanying figure the specific heat (C_v) of an *ideal* Bose-Einstein gas is represented as a function of T/T_0 where

$$T_0 = \frac{h^2}{2\pi m^* k}\left(\frac{n}{2{,}615}\right)^{2/3}.$$

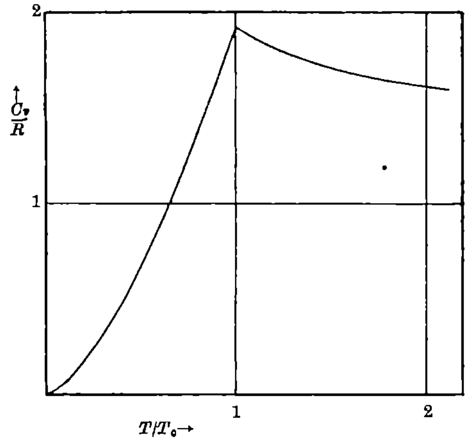
With m^* = the mass of a He atom and with the mol. volume $\frac{N_l}{n} = 27 \cdot 6$ cm.³ one obtains $T_0 = 3 \cdot 09°$. For $T \leqslant T_0$ the specific heat is given by

$$C_v = 1 \cdot 92\, R\, (T/T_0)^{3/2}$$

and for $T \geqslant T_0$ by

$$C_v = \frac{3}{2}\, \mathrm{R}\left[1 + 0 \cdot 231\left(\frac{T_0}{T}\right)^{3/2} + 0 \cdot 046\left(\frac{T_0}{T}\right)^{3} + \ldots\right]$$

The entropy at the transition point T_0 amounts to $1 \cdot 28\, R$ independently of T_0.



SPECIFIC HEAT OF AN IDEAL BOSE-EINSTEIN GAS.

(4) Though actually the λ-point of helium resembles rather a phase transition of second order, it seems difficult not to imagine a connexion with the condensation phenomenon of the Bose-Einstein statistics. The experimental values of the temperature of the λ-point (2·19°) and of its entropy ($\sim 0 \cdot 8\, R$) seem to be in favour of this conception. On the other hand, it is obvious that a model which is so far away from reality that it simplifies liquid helium to an ideal gas, cannot, for high temperatures, yield but the value $C_v = 3/2\, R$, and also for low temperatures the ideal Bose-Einstein gas must, of course, give too great a specific heat, since it does not account for the gradual 'freezing in' of the Debye frequencies.

According to our conception the quantum states of liquid helium would have to correspond, so to speak, to both the states of the electrons and to the Debye vibrational states of the lattice in the theory of metals. It would, of course, be necessary to incorporate this feature into the theory before it can be expected to furnish quantitative insight into the properties of liquid helium.

The conception here proposed might also throw a light on the peculiar transport phenomena observed with He II (enormous conductivity of heat[5], extremely small viscosity[6] and also the strange fountain phenomenon recently discovered by Allen and Jones[2]).

A detailed discussion of these questions will be published in the *Journal de Physique*.

Cross-Sections of the Deuteron for the Electric and Magnetic Nuclear Photo-effect

THE cross-section for the scattering of slow neutrons by protons leads to the assumption of a ^1S level in the deuteron nucleus, with an energy of about 100,000 volts[1]. Fermi[2] showed that the capture of thermal neutrons by protons can be understood qualitatively as a magnetic dipole transition from a ^1S level to the fundamental ^3S level of the deuteron. The amount of the capture cross-section would still depend on the sign of the ^1S level. For a virtual ^1S level, the mean life of neutrons in water (not paraffin) should be $\tau = 2 \cdot 9 \times 10^{-24}$ sec. For a real level $\tau = 6 \cdot 3 \times 10^{-4}$ sec. The values for a virtual level are in good agreement with the recently obtained experimental value[3], $\tau = 2 \cdot 7 \times 10^{-4}$. The evidence obtained by the scattering of thermal neutrons by ortho- and para-hydrogen indicates as well a virtual level[4].

The photo-disintegration of the deuteron by γ-rays may take place by two transitions: the magnetic photo-effect is the inverse of the capture, a ^3S–^1S transition, it leads to uniform angular distribution of the neutrons and protons. The photo-electric effect is due to a ^3S–^3P transition, and consequently the number of protons or neutrons emitted per unit solid angle should be proportional to the sine² of the angle between the incident γ-ray and the photo-particles. The relative contribution of the two photo-effects depends on the sign of the ^1S level. For 2·6 Mev. γ-rays the ratio of the number of neutrons or protons observed in the direction of the incident γ-ray to the number observed at 90° is expected to be

$$I_0/I_{90} = 0 \cdot 29 \text{ for a virtual level}^5.$$
$$= 0 \cdot 13 \text{ for a real level.}$$

Chadwick, Feather and Bretscher[6] observed the angular distribution of 65 photo-protons obtained by the γ-rays of thorium-C′ in a cloud chamber. The total angular distribution seems to show a contribution of the magnetic effect, which is still lower than the one expected for a real level.

I have measured the number of photo-neutrons emitted by a sphere of heavy water (diameter = 10 mm.) in the direction of the γ-rays and at 90° to this direction. As a source 450 mc. of mesothorium were used, the neutrons were detected by the artificial radioactivity of 3 gm. of dysprosium oxide, placed at 33 cm. distance from the heavy water in a paraffin cone of 10° opening. The number of kicks observed at 90° ± 20° to the γ-rays was 700 ± 42, and only 47 ± 40 were observed in the corresponding time at 0° ± 20°. For a pure sine[5] distribution one should expect for the given geometrical conditions at 0°, 5 per cent of the intensity observed at 90°. This result confirms the observation of Chadwick, Feather and Bretscher; the magnetic photo-effect will scarcely yield more than 5 per cent of the photo-electrical intensity observed at 90°, instead of 29 per cent expected. The cross-section of the deuteron for the total photo-effect for 2·64 Mev. γ-rays was obtained by counting the total number of neutrons slowed down in a large tank filled with water, after the method developed by Amaldi and Fermi[7] and Amaldi, Hafstad and Tuve[8]. The total cross-section is found to be $9 \pm 0{\cdot}8 \times 10^{-28}$ cm.^{2}. The cross-section for the electric effect is therefore 9×10^{-28} cm.^{2}, in good agreement with theoretical expectation. An upper limit of 6×10^{-29} cm.^{2} can be indicated for the magnetic effect; this value is much lower than that derived from the capture cross-section of protons for thermal neutrons.

I thank Prof. Urbain for the generous gift of 3 gm. dysprosium oxide and "La société de produits chimiques des terres rares", who kindly lent me the mesothorium source.

Wilson Chamber Study of the Neutro-Electric Effect

In our previous letter describing the results of our Wilson chamber study of the neutro-electric effect[1], we stated that we had found the paired tracks of a proton and an electron in such numbers as would be expected from our counter experiments (assuming the validity of the conservation laws for the energy and momentum).

Since then, we have taken photographs of 10,538 proton tracks; of these 6,448 were taken by using D—D neutrons, and the remaining 4,090 were taken with Li—D neutrons. In each case we found three paired tracks. This is about one sixth of what is expected. Though it is not impossible that they are due to accidental coincidence of the two independent tracks, the fact that we could find no paired track in which the electron starts from the end of the proton track seems to indicate that they are true pairs.

The smaller effect compared with our former result might be explained partly by the fact that the photographs were much clearer in the present case than in the former, and the accuracy of discriminating whether or not the tracks were true pairs was raised considerably, and partly to the statistical fluctuation. No definite conclusion can be drawn from our present result. One may only say that the neutro-electric effect cannot be explained in terms of the direct interaction of the neutron with the atom satisfying the conservation laws, if our previous cross-section determination is not in error by a factor of about 6.

High-Pressure Afterglow in Nitrogen

A most remarkable afterglow in nitrogen has been observed at pressures higher than 10 mm. This afterglow has certain properties which would scarcely be looked for in an afterglow at high pressures. The most striking of these is the relatively strong excitation of the Vegard-Kaplan intercombination bands, which originate on the $A^3\Sigma$-metastable state of nitrogen. Their intensity relative to the usually strong second-positive bands is as high as the intensity in the night-sky afterglow which I reported several years ago[1]. The remarkable nature of this phenomenon will be realized when it is pointed out that the weak night-sky glow was produced at pressures of approximately 0·01 mm. by means of a very feeble exciting discharge, while this strong new glow is produced at about 1,000 times that pressure by means of a very strong exciting discharge. In fact, the relative intensity of these bands has been increasing steadily with pressure in the range so far studied. This is an anomalous result in view of the metastability of the $A^3\Sigma$ level. Moreover, the high-pressure afterglow is more intense and has a longer life than similar glows at lower pressures.

There is present on these afterglow plates a strong line at a wave-length of approximately 3470 A., which has not yet been identified. Its behaviour, as the tube cleans up and the nitrogen becomes purer, is now being studied. It is important, too, that a relatively strong unidentified line or band has been reported by both Dufay[2] and Gauzit[3] in the light of the night sky at a wave-length of 3471 A. The presence of this line in the new high-pressure afterglow, in companionship with the Vegard-Kaplan bands, which are strong in the light of the night sky, suggests that it may be the hitherto unobserved atomic nitrogen line $^2P - {}^4S$, the predicted position of which is also 3470 A. If this be true, then the auroral transition $^2P - {}^2D$ should be much stronger in the afterglow, as well as in the light of the night sky, than 3470 A. The approximate position of the components of the $^2P - {}^2D$ transition is at 1·0373 μ, and until it is observed in the present experiments or in the light of the night sky, the above proposed identification of the 3470 line as the trans-auroral transition $^2P - {}^4S$ should be considered tentative. It may be pointed out, however, that the infra-red lines at 1·0373 μ would be the nitrogen analogue of the well-known auroral green line.

Added weight is given to the identification of the 3470 line as the unknown atomic nitrogen line, rather than as the second-positive band at 3469, by the fact that the second-positive bands, which are usually stronger than 3469, are either absent or weaker in the light of the night sky. A discovery of this significance for the physics of the upper atmosphere must be carefully considered, and a programme of exhaustive investigation of the 3470 line is now under way. Until further study, therefore, the identification must be given as a tentative one, attractive as the above arguments may sound.

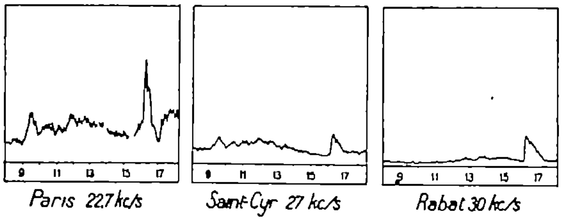
Effect of Catastrophic Ionospheric Disturbances on Low-Frequency Radio Waves

K. G. Budden and J. A. Ratcliffe[1] have described an effect of catastrophic ionospheric disturbances on low-frequency radio waves (16 kc./s.), but this action did not show an increase in atmospherics.

This last statement agrees with our observations. It is certain that an increase in atmospherics seldom appears on a frequency of 12 kc./s. This has been known for several years. A recent observation shows that, on a frequency of 17 kc./s., increase had already disappeared.



Increases noticed at Paris (22 kc./s.), St. Cyr (27 kc./s.) and Rabat (30 kc./s.) on November 6, 1936 (date of the anomally published by K. G. Budden and J. A. Ratcliffe), are shown on the accompanying figure.

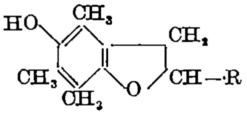
Vitamin E: Structure of β-Tocopherol

IN a recent publication[1] we indicated that β-tocopherol, $C_{28}H_{48}O_2$, might be a coumaran or chroman derivative bearing a long side chain in the heterocyclic nucleus.

With the view of testing this hypothesis, we have synthesized 5-hydroxy-2 : 4 : 6 : 7-tetramethylcoumaran (I), m.p. 124–125°, starting from pseudocumoquinol and allyl bromide, and also 5-hydroxy-4 : 6 : 7-trimethyl-2-*n*-heptadecylcoumaran (II), m.p. 95–95·5°, isomeric with β-tocopherol, from pseudocumoquinone and ethylsodiostearoylacetate followed by partial hydrogenation of the intermediate coumarone.



I R = CH_3

II R = $C_{17}H_{35}$

Both the synthetic coumarans are very similar to β-tocopherol in absorption spectrum and reducing properties.

Substance	Wave-length		ε mol	
	Max.	Min.	Max.	Min.
β-tocopherol . . .	295mμ	260mμ	3577	520
'Heptadecylcoumaran' . .	297mμ	258mμ	3993	624
'Methylcoumaran' . .	296mμ	270mμ	3840	1305

When thermal decomposition is attempted, synthetic 5-hydroxy-4 : 6 : 7-trimethyl-2-*n*-heptadecylcoumaran distils at 370° without charring, giving a mixture from which a trace of a quinol is obtained, m.p. 185–190° (subl.) (cf. thermal decomposition of tocopherols, *loc. cit.*).

These results together with the surface film measurements of Dr. Danielli, recorded below, give support to the view that β-tocopherol is a coumaran derivative. The detailed configuration of the side chain, and the distribution of CH_3-groups in the ring system remain to be determined. Side methyl estimations of β-tocopherol indicate the presence of six or seven $CH_3(C)$. Two or possibly three of these can be attached to the aromatic nucleus; the remaining three to five can be accounted for by formulating the side chain and the heterocyclic nucleus as a 'dihydrophytyl'-like structure; such a structure would explain also the oily nature of the vitamin and the ready production of quinols on thermal decomposition. This hypothesis is supported by results of oxidation: two oily fatty acids, C_{17-18} and C_{11-12}, are obtained, giving crystalline phenylphenacylesters.

Both β-tocopherol allophanate and 5-hydroxy-4 : 6 : 7-trimethyl-2-*n*-heptadecylcoumarone spread on *N*/100 hydrochloric acid to give stable films. The limiting area of the first compound is 30 sq. A. and that of the coumarone is 26 sq. A. *p*-Hexadecylcyclohexanol has a limiting area of 30 sq. A. and the lactone of γ-hydroxystearic acid an area of 29 sq. A. It may therefore be concluded that the first two compounds mentioned are analogous in structure and that in cross-section β-tocopherol cannot have a ring system more than one ring in thickness measured perpendicular to the side chain. The ring system cannot be analogous to a phenanthrene or sterol skeleton.

Function of Carbon Dioxide in the Metabolism of Heterotrophic Cells

In recent years the indispensability of small quantities of carbon dioxide for the growth of very diverse heterotrophic cells has been amply demonstrated. For a fairly recent survey of literature, reference may be made to the paper of Gladstone, Fildes and Richardson[1]. Until now, however, no explanation has been given for this unexpected phenomenon.

Two possibilities present themselves. In the first place, the fact that very common types of bacteria, yeasts and fungi proliferate in a given medium if traces of carbon dioxide are present, but do not do so in its absence, may mean that carbon dioxide is the starting point for the synthesis of some essential cell constituent. This implies, of course, that carbon dioxide will be chemically converted, or in other words reduced, by the heterotrophic cells of the inoculum. Although it seems improbable that this power is a universal property of the numerous heterotrophic organisms for which the indispensability of carbon dioxide has already been demonstrated, the possibility cannot be at once rejected in view of the results obtained in the recent studies of Woods[2], Wood and Werkman[3], Barker[4] and others.

It may, however, suffice to state here that all attempts made so far to obtain experimental evidence in favour of this assumption have been unsuccessful.

A second possible explanation for the necessity of carbon dioxide for the growth of heterotrophic cells might be sought in a demonstration that this compound is essential for the functioning of the energy-yielding reactions normally occurring in the cells of the inoculum. Since only aerobic organisms have been studied, this would mean that the ultimate removal of carbon dioxide from the cells interferes with the respiration process. This would imply that carbon dioxide is not only essential for the proliferation of heterotrophic cells, but also for the respiration of a suspension of preformed 'resting cells'.

After experiments to test this hypothesis had already been started, I found that a similar suggestion had been made by Krebs[5], who, however, did not offer experimental support for his assumption that carbon dioxide might act as a hydrogen carrier in the respiration of *B. coli*.

I have now succeeded in proving that carbon dioxide is, indeed, essential in the normal functioning of the oxidation-reduction catalysts in various heterotrophic cells, in so far at least that complete removal of carbon dioxide leads to an inhibition of methylene blue reduction. It was found that this reduction under the usual conditions is fully prevented if the medium is rigorously freed from the last traces of carbon dioxide previous to the test. For this purpose, some solid caustic potash was placed in the side bulb of a Thunberg-Keilin tube, and the tubes were shaken, keeping them at a temperature of 0° C. to prevent reduction before the removal of the carbon dioxide was completed. After some hours the tubes were incubated in a water bath at 37° C. in order to test whether or not reduction of the dye would occur. Using *B. coli* or *B. prodigiosum* as test organisms, no reduction took place although the experiment was continued for 24 hours; control tubes submitted to a similar pre-treatment, with calcium chloride instead of caustic potash in the side bulb, readily reduced the methylene blue.

With organisms like *Saccharomyces ellipsoideus* (Chambertin yeast), *Aspergillus niger* or *Prototheca* species which ordinarily contain large quantities of reserve carbohydrates—easily leading to carbon dioxide production in the cells—no absolute inhibition of methylene blue reduction could be obtained, but the time necessary for the reduction was considerably prolonged, showing that here the same condition prevails.

I am much indebted to Prof. A. J. Kluyver at Delft (Holland) for his kind help in guiding me with many suggestions during the investigation.

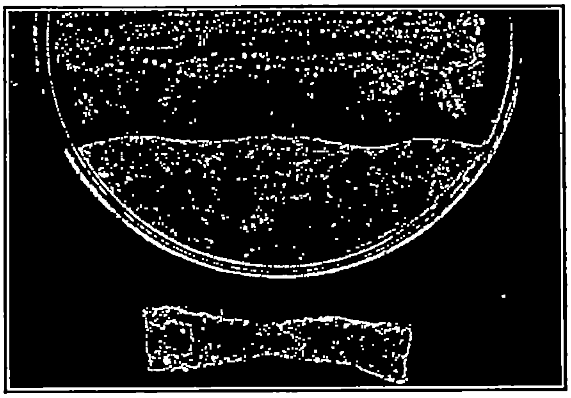
Dissolving Action of Micro-Organisms on Milk-Wool

Milk-wool is now becoming of universal interest, and samples are being shown now and then of textile products containing 50 or even 100 per cent of this material. It appears to us, however, that due consideration should be given to the question, whether these products can withstand the biological agencies provided by Nature in the form of organisms able to assimilate and mineralize protein substances of the class to which casein belongs.



Above: Milk-wool plate Dissolving action of micro-organisms.
Below: Piece of 100 per cent milk-wool textile.
Left: two holes, caused by sterile pieces of clarified milk-wool agar Right: piece of same agar, non-inoculated, as control (no change).

These considerations have induced us to investigate the possibility of isolating casein-splitting organisms, which are also capable of attacking the formol-hardened casein, milk-wool.

It was found that nearly all casein-splitting micro-organisms, isolated from soil or manure, or gathered by infection from the ordinary atmosphere, are able to attack the wool. They belong to all classes: bacteria, moulds, actinomyces, many of which show a very strong dissolving action when grown on water-agar plates containing the usual inorganic salts and finely divided milk-wool threads. These organisms invariably act by an exo-enzyme, and so a fairly large zone is developed around the places of their growth, where every thread of milk-wool is dissolved and the milky white agar has become completely transparent. Pieces of agar from this zone, when applied to a piece of textile material of 50 per cent milk-wool, were able to destroy all the milk-wool beneath them, leaving the 50 per cent of genuine wool unattacked. The 100 per cent milk-wool textile was completely dissolved, resulting in a hole after two days, as the accompanying illustration shows. The enzyme was inactivated by boiling.

The direct action of the micro-organisms, when applied to pieces of textile material, lying on agar-plates, which contained only inorganic salts, was equally deleterious.

The experiments are being continued in several directions.

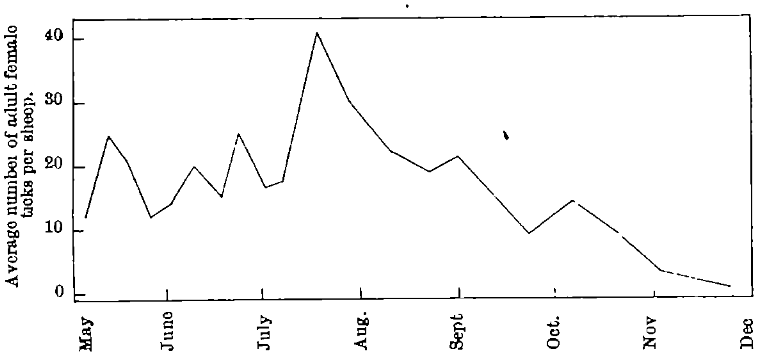
Activity of the Sheep Tick

THE activity of the sheep or grass tick, *Ixodes ricinus* L., in Great Britain has been reported by various workers[1,2,3] to be confined to two periods of the year: (*a*) spring activity, extending from March until early June, (*b*) autumn activity, from late August until the end of September. Outside these periods, ticks are said to be scarce during the summer months and completely inactive in winter.

In the spring of 1937, an investigation was commenced by us upon the incidence of *Ixodes ricinus* in the Deeside area, and it has been found that its activity differs very widely from that reported in other parts of the country.

The accompanying graph, showing the seasonal activity upon one hill-grazing, is representative of data obtained from several holdings. In making the tick counts upon the sheep, only the adult females upon the head and neck and on the bare skin beneath the forelegs were counted. This method, which is also in use by other observers, enables one worker to examine large numbers of sheep and allows some comparison to be made with the results obtained by other workers.



SEASONAL ACTIVITY OF TICKS IN NORTH-EAST SCOTLAND

From observations made upon hares previous to the sheep being placed upon the hill, the ticks had already begun their activity in this district during the first week in April. The sheep were attacked as soon as they grazed upon the hill and the infestation progressively increased to a peak in the month of July, after which there was a gradual decrease. When the sheep were removed from the hill on November 25 there was still an average infestation of 0·5 ticks per sheep.

During the month of December the worst snowstorm for many years swept the country, and we assumed the ticks would become inactive for the remainder of the winter.

On January 12, 1938, two stags were shot which had ticks attached, one a fully engorged female, which, from its appearance, had become attached about ten days previously, when the hills were still covered with snow. This female commenced egg-laying on February 5.

On January 27, a flock of sheep upon a tick-infested pasture on another hill were found to have an average of 1·5 adult female ticks attached to the head and neck and the bare skin beneath the legs, in addition to large numbers of males, nymphs and larvæ. Five deer, which were shot on this date, were found to be carrying a total of 42 adult female and 25 male ticks. The flock of sheep was again examined on February 9 and had an average of 1·2 female ticks attached.

From these observations it appears that tick activity is continuous throughout the year in north-east Scotland, the seasonal incidence being greatest during the summer and lowest in winter.

Further work upon this problem, aided by a grant from the Agricultural Research Council, is proceeding, and detailed results will be published elsewhere.

Tube Formation in *Pomatoceros triqueter* (L.)

AMONG the scientific effects of the late Frank A. Potts was found the following account of tube formation in the serpulid worm *Pomatoceros triqueter*, a subject on which he had been working intermittently for some time.

The apparently homogeneous keeled tube is seen in longitudinal section to be composed of successive rings of calcium carbonate. The substance of the tube is of a mucoid nature in which small crystals of aragonite are deposited. Each successive ring is formed by the peristomial collar which arises from the ventral wall. As the animal lies on its back, the ventral surface with the collar is uppermost.

When the animal is removed from its tube it will live for an indefinite period, and in normal sea water will form one or two calcareous rings. If instead of normal sea water artificial sea water (Dittmar's formula) is used, the worms live almost as well as in normal sea water and produce rings with equal facility. If the animals are taken out of their tubes and placed in artificial calcium-free sea water, they will live for a number of days and are apparently normal, but they do not produce calcareous rings. Animals which have been kept like this in calcium-free sea water, if transferred back to normal sea water, produce calcareous rings. If animals removed from their tubes are placed in artificial sea water in which there is half the amount of calcium chloride required by Dittmar's formula, that is, about 210 mgm. instead of 420 mgm. calcium per litre, they will form rings at roughly the same rate of deposition as when the normal amount of calcium chloride is present. From preliminary experiments, it appears that the amount of calcium can be further reduced without inhibiting the production of calcium carbonate.

The above experiments show an independence of food in the calcium carbonate forming activities. If worms which have been feeding are at once removed to calcium-free sea water, they are unable to form the calcareous rings. There are no organs in *Pomatoceros* which might act as special stores of calcium. If the blood be considered as a possible store of calcium, it may be mentioned that the frequent severe hæmorrhage which occurs on removing the worm from its tube does not interfere with the immediate production of calcareous rings. The evidence so far collected points to the sea water as the source of the calcium required for tube building.

In Nature the production of the calcareous tube begins in March and goes on until August or September. The length of life of *Pomatoceros* is from two to three years at least. The animal begins its tube building activities in the spring presumably about the time it begins to feed, and it builds its tube continuously until the autumn.

Relation between Structure of Pine Leaves and their Position on the Tree

The quantitative anatomical method has recently acquired an increasing importance in determining the face, the form, or even the variety of various cultivated plants. It has also been applied in the study of the leaf of the pine (*Pinus silvestris* L.)[1,2,3]. Unfortunately, however, scarcely any of the investigators have considered the position on the tree to which are attached the leaves taken for study. Whereas, so early as 1904, Zalensky[4] discovered the law which has, in the Russian literature, acquired the name of 'Zalensky's law' (Maximov[5]), but which, unfortunately, remained unknown in western Europe and was considerably later rediscovered by a number of investigators[6]. Zalensky, studying monocotyledonous and dicotyledonous plants on a very extensive and variegated material, showed that the higher up on the tree the leaf grows (or the nearer to the end of the branch) the greater the xeromorphic properties it acquires; that is, the epidermis and mesophyll cells are smaller, the conducting strand is thicker, the cuticle and wax coating are thicker, the stomata are greater in number and smaller, the palisade tissue is more clearly defined. It was to be expected that a similar law would be found for Gymnospermæ, except that, in connexion with the peculiar structure of the leaf in conifers, it would take a slightly different form.

An investigation of the leaves of several pines by stages confirmed this supposition. It was shown that the higher up on the tree (or closer to the end of the branch) the leaf grows, the longer, broader, and thicker it is; the central cylinder is wider and thicker, the conducting bundles are larger, the resin canals are greater in number and larger, the epidermis is thicker. The difference between the upper and lower stages of hundred-year-old pines in the length and breadth of the leaves, in the thickness of the conducting tissue, in the number of resin canals, reaches 25 per cent[7].

Thus, in every quantitative anatomical study of the leaves of *Pinus*, it is necessary to choose material for comparison from the same regions on the tree, which have grown under similar conditions. Failure to observe this rule may completely destroy the value of the results of the investigation.

Blood Groups of the Noluas of Bengal

The Noluas are a group of people who collect reeds and manufacture different types of basket from it. They live in four districts of Bengal—Jessore, Khulna, Faridpur and Nadia. Their total strength is 1,704-884 males and 820 females. They are a short-statured, mesocephalic and mesorrhine people.

I examined the blood of 100 adult male Noluas of four districts, 25 from each. All the samples were examined carefully with fresh standard serum. The following are the data which I obtained: group *O*, 16 per cent; group *A*, 38 per cent; group *B*, 33 per cent; group *AB*, 13 per cent.

"Clay"

In Nature of April 2, Dr. A. B. Searle refers at some length to a discourse on clay which I gave at the Royal Institution a few months ago. Dr. Searle is too generous to me in his account of our present knowledge of clay structure. The application of the X-ray methods to this difficult but most interesting problem was, in the first place, based on the silicate investigations at Manchester, and has been made by many workers, especially by Pauling and his collaborators in the United States, and by Nagelschmidt and others in Germany and Great Britain. My discourse was a brief summary and comment on the work done and doing by others than myself.

A Shortened Method of Estimation of Mental Factors by Regression

A type of problem of estimation with which one meets in the theory of mental factors is this: a team of n tests z_i ($i = 1, 2, \ldots, n$) has been analysed into r common factors $f_{0\alpha}$ ($\alpha = 1, 2, \ldots r$) and n specifics f_{1i}, all of which are normalized and uncorrelated, but otherwise unknown. The observed test-scores (in standard measure) can then, in matrix notation, be represented as follows.

$$z = M_0 f_0 + M_1 f_1,$$

where the column vectors z, f_0 and f_1 indicate the tests, the common factors and the specifics respectively. The matrices M_0 and M_1 whose elements are the loadings of the tests with the hypothetical factors, are regarded as known. When it is desired to estimate the common factors in terms of the test-scores, the usual regression method leads to the formula:

$$\hat{f}_0 = M'_0(M_0 M'_0 + M_1^2)^{-1} z, \quad \ldots \quad (1)$$

where $\hat{f}_0$ is the estimate of f_0.

If the number of tests, n, is large, the evaluation of this expression is very laborious, since it involves calculating the reciprocal of the n-rowed matrix $M_0 M'_0 + M_1^2$. However, according to L. L. Thurstone, the number of common factors, r, is in most practical cases much smaller than the number of tests; in these circumstances it is more convenient to use the formula:

$$\hat{f}_0 = (I + M'_0 M_1^{-2} M_0)^{-1} M'_0 M_1^{-2} z, \quad \ldots \quad (2)$$

in which now only the reciprocal of an r-rowed matrix is required.

Formula (2) is an extension to multiple factor analysis of a formula which Prof. C. Spearman has derived for the estimation of the 'general factor' g in the theory of two factors.

A more detailed account of this will be given elsewhere.

Walter Ledermann.

Points from Foregoing Letters

In an investigation of the capture γ-radiation produced by protons in carbon, P. I. Dee, S. C. Curran and V. Petržílka find that there are two resonances. One of these, at 400 kv., is due to ^{12}C, the other, at 500 kv., is due to ^{13}C. The energies of the capture γ-radiations have been measured, giving for ^{12}C the value 2·6 Mv. and for ^{13}C the value 7·4 Mv. These values agree with those to be expected from the known mass values.

From energetics considerations, Dr. F. London concludes that a spatial model of liquid helium II such as that proposed by Frölich to explain the λ-transition point is not possible. The author describes, instead, a kinetic model in which each helium atom moves in a self-consistent periodic field formed by the other atoms. He calculates the specific heat of such a system by applying Bose-Einstein statistics on the very rough simplifying assumption of 'ideal gas' conditions. The author considers that his view may throw light on the large heat conductivity and the small viscosity of helium II.

The cross-section for the total nuclear photo-effect of the deuteron for 2·64 Mev. γ-rays has been determined by Dr. H. v. Halban, jun. The relative contributions of the electric and magnetic effects were separated by counting the number of photo-neutrons projected in the direction of the incident γ-ray and at 90° to this direction. The cross-section found for the magnetic effect is lower than would be expected from the capture cross-section of protons for thermal neutrons.

Among some 10,000 proton tracks obtained by using D—D and Li—D neutrons and photographed in a Wilson chamber, S. Kikuchi and H. Aoki have found only six pairs, a smaller proportion than formerly noticed, and only one sixth of the expected number on the basis of the 'neutro-electric effect.'

An unusual intense nitrogen afterglow has been produced by Prof. J. Kaplan at pressures higher than 10 mm. Its spectrum is rich in bands of the Vegard–Kaplan intercombination system and contains a strong line at 3470 A. which is tentatively identified as the hitherto unobserved trans-auroral line $^2P - {}^4S$. There is a fairly strong line at this wave-length in the light of the night sky. A search is now being made for the $^2P - {}^2D$ lines in the high-pressure glow. These should lie around 1·0373 μ and would be the nitrogen analogues of the well-known green auroral line.

Further investigations towards elucidating the structure of the anti-sterility vitamin E are reported by Dr. F. Bergel, A. Jacob, A. R. Todd and T. S. Work. From the fact that a synthetic coumaran derivative behaves similarly to β-tocopherol upon thermal decomposition and from surface film measurements carried out by Dr. J. F. Danielli, they conclude that β-tocopherol is a coumaran derivative.

Dr. J. W. Hes finds that the complete removal of carbon dioxide interferes with the oxidation-reduction power (as shown by the methylene blue reaction) in the case of heterotrophic cells, that is, bacteria and other low organisms which cannot synthesize proteins and carbohydrates from inorganic constituents. This explains the indispensability of carbon dioxide for the growth of such organisms.

Prof. Jan Smit and B. van der Heide report on experiments showing that milk-wool, made from milk-casein, is readily attacked by many kinds of micro-organisms, which may thus affect durability of textile products made from that substance. The dissolving action was likewise shown by sterile pieces of the milk-wool agar, on which the organisms were grown, and taken from places where the wool had been dissolved by an exo-enzyme. The enzyme was destroyed by heating the agar.

A study of the formation of the calcareous tube of the serpulid worm *Pomatoceros triqueter* by the late Frank A. Potts, reported by J. D. Robertson and Dr. C. F. A. Pantin, has shown that the source of calcium for the tube is probably the sea water. Tube building in this polychæte extends from March to September.

Research Items

'Bone Age' Man

The Abbé Breuil in *Antiquity* of March argues for a much more extensive use of bone in the earlier phases of the Palæolithic period than is at present conceded by archæologists. In the Later Palæolithic period, the technique of bone is already far advanced, and the implements must have had more ancient prototypes; but in fact the only Middle Palæolithic examples known of bone-working by means of attrition and scraping are few in number—rib-bones sharpened by rubbing, occasional awls similarly sharpened, and two large spear-points of the Upper Mousterian from Castillo and La Quina, to which might be added the anvil blocks and trimming tools discovered by Dr. H. Martin. Further, stone suitable for implements does not occur everywhere, and the technique of its working is a process of long development. Therefore some authorities postulate an age of bone and wood. Man in the dawn of the industrial phase would naturally take the remains of animals killed by him, horns, antlers and bones, to use against them. The long bones would make excellent clubs, while others in their natural state could be used for pricking and piercing, or as planes and hammers, either in the natural state or when broken by a pebble. Bones, however, gnawed by carnivores or rodents show marks suggesting human workmanship, which are apt to deceive the archæologist. The bone claimed to have been worked by Piltdown man is an instance in point. Evidence for the use of slightly modified parts of his victim by early man is afforded in the cave of Castillo (Santandar, Spain) and Choukoutien (Peking). The evidence of the horns of ruminants and deer antlers, of skulls or parts of skulls, of jaw bones and long bones, of shoulder, iliac and trunk bones from both sources suggest the belief, at least, that at some ancient epoch the use of bones may have been of more importance than the use of stone.

Ainu Marriage Ceremonial

In an account of a traditional oration or song intoned or sung at an Ainu marriage which Dr. N. Gordon Munro collected from an Ainu learned in the lore of his people (*Man*, March 1938) he records the order of ceremonial in which the song was introduced. The song itself belongs to a class *Yai-kuru-e-karapa*, meaning personal speech-making, a term used only of an address on a felicitous occasion, but never for a funeral oration or at any other sad event. At a wedding, it is delivered by the father of the bride. On the occasion here recorded the song indicated that the daughter was an only child, and there is a hint of anxiety now relieved by the prospect of her children continuing the line. The bridegroom has been approved, more particularly as to his line of descent. Ainu society was matrilineal and rigidly exogamous, the evidence of descent of each group from an eponymous ancestress being furnished by a secret girdle, which no man dare examine and which it was taboo even to mention. It is a cord conventionally taken to signify a particular ancestral source, according to its length and consequently the number of times it is folded to make a girdle. Elderly women, who treasure their esoteric knowledge, decide whether the girdle of the man's mother bears testimony to a descent other than that of the girl. All preliminaries ended and marriage gifts exchanged (there is no bride-price), and the most revered and trusted Kamui Fuchi—spirit ancestress of all Ainu who comes to light in the hearth-fire—having been solicited, all is in order. The bridegroom has sent to the home of the bride material for the sacred brew, which takes a week to make from millet with ritual precautions. When the guests have assembled for the feast, the father makes a speech or recitative in poetic form, which preludes the ancient rite of handing the cup of the sacred brew to the bridegroom, who drinks half and gives the remainder to his bride. Should she refuse it there is no marriage. The bride takes the cup and raises it to the level of her forehead, swings it gently thrice to right and left, drinks, and then performs the characteristic feminine gesture of *rai-mik*, in which the forefinger of the right hand is drawn from that of the left hand up the arm and across the upper lip.

Influence of Circulation on Size of Blood Vessels

By means of an indirectly illuminating microscope and a moist, warm chamber it is possible to study development of the vascular system in a living chick blastoderm still on its yolk for a period of seven days. This method was chosen by A. F. W. Hughes (*J. Anat.*, 72, Oct. 1937) to investigate the influence of the rate of circulation of the blood upon the diameter of the blood vessels. The rate of flow in the arteries and veins of the area vasculosa was determined by measuring the speed of the corpuscles in the margins of the vessels, and is termed the 'marginal velocity'. In the first ten hours the increase in diameter of the vessels may be 40 per cent per hour and the marginal velocity 4 mm. per sec. During the third and fourth days the marginal velocity drops to 1·2 mm. per sec. and the increase in diameter to 5 per cent per hour. Thus there is a correlation between marginal velocity and rate of increase in diameter of the vessels; the relationship, however, is not a simple mathematical one. In arteries, the mitotic rate of the endothelium is sufficient to account for the increase of diameter. When the veins are increasing rapidly in diameter, however, the mitotic rate of the endothelium is only sufficient to account for about one fifth of the increase in diameter. Since no noticeable increase in cell size is discernible, it is suggested that the remaining four fifths of the cells are supplied by the immigration of cells from the adjacent mesenchyme.

Crabs of America

Miss Mary J. Rathbun completes her series of handbooks on American crabs in a fourth volume, "The Oxystomatous and Allied Crabs of America" (United States National Museum. Bulletin 166. 1937). The former volumes have dealt with grapsoid crabs (Bulletin 97), spider crabs (Bulletin 129) and cancroid crabs (Bulletin 152). All these works are based on an enormous amount of material and the whole is exceedingly valuable. Carcinologists are fortunate in having this complete work by one of the greatest authorities on the subject. The present volume includes Gymnopleura, Oxystomata and

Dromiacea; also the Haplocarcinidea, the position of which in the Brachyura is uncertain, and one single example of *Geryon* (Brachygnatha) omitted previously from the volume on Grapsoids. The Dromiacea are still regarded as belonging to the Brachyura in spite of the fact that the larvæ differ entirely from any brachyuran zoea. The Oxystomata are the largest group represented and occupy the greater part of the volume (pp. 75–258). In this sub-tribe are many very interesting forms, some of peculiar shape, some so exactly resembling the pebbles in which they live that it is difficult, if not impossible, to detect them in their natural surroundings. The Calappidæ with their large chelæ which cover the ventral surface are also included here. The 86 plates, mainly from photographs, are good and clear.

Indian Brackish Water Fauna

N. Kesava Panikkar and R. Gopala Aiyar (*Proc. Ind. Acad. Sci.*, 6, Nov. 1937) have investigated the fauna of the brackish waters in the neighbourhood of Madras, particularly in regard to its relation to its habitat. The temperature of the water varies during the year from 25·0° C. to 29·6° C., its *p*H from 8·48 to 9·15, its salinity from 16·91 to 30·44 per mille. The change from marine to brackish water conditions is somewhat abrupt. Ninety-two species of invertebrates, eighty belonging to typically marine groups, are recorded, and this excludes Protozoa and Rotifera. The majority of the fifty-four fishes recorded are more or less permanent inhabitants; seven freshwater species and a few casual or seasonal migrants comprise the remainder. The fauna on the whole is typically marine. The animals are discussed from the point of view of their ecology and adaptation to their environment, which is described in detail. The vertical and regional distribution of the organisms is described, and there is a discussion of the general problems of the biology of animals in brackish water in the light of the facts brought forward.

Osmotic Values of Plant Tissue under Snow

During the British East Greenland Expedition of 1935–36 under the leadership of Dr. L. R. Wager, Dr. and Mrs. H. G. Wager carried out observations throughout the year upon the osmotic values of typical plants in Kangerdlugssuak, East Greenland. The osmotic values were determined by a plasmolytic method using sections or stripped portions of the epidermis and cane sugar solutions. Some of the species examined showed a sharp rise in osmotic value in late autumn, probably associated with the falling temperature both directly and indirectly, through the fact that the soil water was thus rendered unavailable. The most interesting result is the fact that five plants—two species of *Salix*, *Empetrum*, *Viscaria* and *Cassiope*—show a marked fall in osmotic value during the winter, whilst buried under the snow. The authors suggest that this is probably associated with a change in the water balance. Under the snow the air is continually saturated with water vapour and the water shortage in autumn, very clearly shown in some species by the shrunken protoplasts when examined in oil, no longer exists, the cells slowly saturate with water and the osmotic pressure falls. Comparison between the osmotic values of some of the same plants grown throughout the seasons in Dublin suggest, however, that the group of factors determining the seasonal changes of osmotic pressure is very complex.

Disease of Australian Pines

A progress report for 1936–37 entitled "Needle Fusion of Species of *Pinus* in Southern New South Wales" by W. V. Ludbrook has been issued (Melbourne, 1937) discussing the disease known as 'needle fusion', 'fused needle', or 'curly needle', which is confined to Australasia, being important chiefly in Queensland, Tasmania and the coastal plantations of New South Wales. Investigations appear to show that it is severe only when the soil conditions are unsuitable to the trees planted, a case which has other parallels elsewhere with introduced exotics. There is no evidence that it is infectious, though the cause of the disease is still unknown. It is said that the commercial value of severely affected trees is permanently destroyed. Diseased trees exhibit varying degrees of stunting, die-back and needle abnormality, but are rarely, if ever, killed by the disease. The symptoms commonly appear 3–7 years after the trees have been planted. The majority of the species of *Pinus* commonly grown for afforestation in Australia are susceptible, *P. pinaster* being the chief exception. *P. caribea* appears to be relatively resistant. It is said that there is little or no chance that the disease will cause appreciable loss in plantations where the soil and climatic conditions are satisfactory. In Queensland, climatic conditions are very different from those where the investigations were made, so that the conclusions arrived at may not be applicable.

Fusarium culmorum on Wheat

The fungus *Fusarium culmorum* has been described as the cause of various diseases of wheat, but modern investigations do not incriminate it strongly. G. Samuel and F. J. Greaney have, in fact, isolated it from healthy, high-yielding crops in three localities in the south of England (*Trans. Brit. Mycol. Soc.*, 21, Pts. 1 and 2, 114–117; 1937). One crop obtained the gold cup at the Bakers' Exhibition in London, yet in spite of this undoubted hall-mark, its roots and stems harboured *F. culmorum*. Very numerous isolates of the fungus were all mildly pathogenic under greenhouse conditions, and there would appear to be other evidence that the fungus really does cause damage in the northern parts of Great Britain. Such findings emphasize the need for greater development of the ecological side of plant pathology. A close alliance of laboratory studies and field estimations over a wide area is absolutely necessary for the correct evaluation of any host-fungus relationship.

Oceanic Sedimentation

From the stratification of the bottom samples collected during the *Meteor* Expedition, Schott, in 1935, calculated the average rate of deep-sea sedimentation at 1 cm. per 1,000 years. This estimate was based on the reasonable assumption that 20,000 years have elapsed since the climate was considerably colder than at present. In an interesting study of the problems raised by such rapid sedimentation, Ph. H. Kuenen (*Amer. J. Sci.*, Dec. 1937) points out that Schott's estimate appears to imply a total thickness of deep-sea sediments amounting to about 17 km. This, in turn, implies denudation of the continents of about 40 km., which is evidently far too high to be acceptable. Two modifying factors have to be considered, however, namely, compaction of the sediments, and the steady production of eruptive rocks throughout geological time. Appropriate estimates of the effects of these factors then bring Schott's figures into close agreement with the results of other denudational statistics. It is concluded that the thickness of deep-sea deposits may be of the order 5–6 km. The bearing of such a thickness on isostasy, temperature at the lower surface of the oceanic crust, seismic propagation, the thickness of the continents, and the mechanism of continental drift is discussed. Kuenen shows that if South America drifted westwards for 3,000 km., the piled up oozes would, after complete isostatic compensation, form a mass equivalent to a plateau 200 km. broad at sea-level. Actually, the continental slope is there one of the steepest in the world and is fronted by deep-sea troughs. Evidently the problem of oceanic sedimentation is involved with others which cannot yet be easily solved.

Origins of Magmas

IN a stimulating paper on "The Origin of the Pacific Magma Types in the Volcanic Inner-arc of the Soenda Mountain System" (*De Ingenieur in Ned.-Indie*, No. 1 ; 1938), R. W. van Bemmelen reaches some petrogenetic conclusions of far-reaching importance. He points out that three different ways of magma generation may now be distinguished : (1) differentiation of a parental magma (primary or juvenile magmas) ; (2) magmatization of pre-existing crustal rocks by ascending emanations from the substratum (palingenetic magmas, now becoming more familiar as rheomorphic magmas) ; and (3) hybridization or contamination of juvenile or palingenetic magmas by assimilation of foreign material (syntectic or mixed magmas). On the basis of geological field observations, together with petrological and petrochemical investigations, in the area under review, the author comes to the conclusion that there are few direct indications of (1), whereas (2) and (3) are of great importance for the origin of calc-alkali or Pacific magma types. The observations strongly point to the possibility that at least part of the various types of Pacific igneous rocks are *not* the product of gravitational crystallization differentiation of a gabbroic parent magma, as has been commonly assumed, but that they are the result of the ascent of magmatic emanations, containing mainly silicon, aluminium and alkalis, whereby the sialic crustal rocks became locally magmatized. A valuable feature of the paper is the review which it contains of the recent literature relevant to the subject of magma formation.

Impact Stresses

IN a paper read before the Scottish Section of the Institution of Mechanical Engineers at Glasgow on March 3, it was demonstrated that stresses caused by impact loads may and do differ materially from those calculated on the assumption of statical equivalence. The subject of the research—described by Mr. R. N. Arnold under the title "Impact Stresses in a Freely Supported Beam"—was a portion of railway rail, 8 ft. span, and the bending stresses induced were found to be 20 per cent higher than those calculated on this assumption. The beam was subjected to impact loads by dropping weights of magnitude up to 470 lb. from different heights and at intervals of 4 in. along its length ; records of its deflections were made by means of a scratch extensometer, the construction of which is described. These show the occurrence of 'sub-impacts'—the weight, in some cases, striking the rail five times in what appeared to be a single impact. At the centre of the beam the deflections are seen to be initially positive, but at distances of 16 in. and more from the centre they prove to be initially negative and to become positive as the impact proceeds, thus showing a distinct divergence from the conditions of static bending. The analysis of the results obtained in this way and also by the use of thin pieces of paper inserted between the rail and the falling weight leads to the conclusions that impact effects, even in comparatively simple settings, are in general much more complicated than is supposed, and that while the ordinary methods give fair approximations for deflections, the errors which they introduce in the bending moments and stresses are excessive. This research had particular reference to the impact loads to which railway rails are subject due to such causes as non-circular wheels, rail irregularities, joints and crossings and to the trouble experienced with fatigue cracks. These grow internally in the head of the rail and are especially dangerous because their existence may be quite unsuspected until fracture occurs. Similar internal fissures have been produced by prolonged repetitions of a rolling load on a rail, and wheel impact load rather than bending moment has been indicated as the stress-determining factor. The results of the present series of tests are held to have exhibited the complexity of impact effects and the probability that the actual loads may be much more severe than are predicted by the usual approximate theories.

State of the Outer Planets

DR. HAROLD JEFFREYS has recently published a note on the state of the outer planets (*Mon. Not. Roy. Astro. Soc.*, 98, 3 ; Jan. 1938) in which he corrects certain misinterpretations of his previous papers on the cold conditions prevailing on the outer planets. His paper is largely suggested by Mr. B. M. Peek's paper (*Mon. Not. Roy. Astro. Soc.*, June 1937), where doubts are expressed regarding the deep atmosphere and thick layer of ice on Jupiter. In Dr. Jeffreys's second paper (*Mon. Not. Roy. Astro. Soc.* **84** ; 1924), he pointed out that an explanation of the observed radiation of Jupiter and Saturn—appreciably larger than it was possible to explain by solar radiation—would be possible if the planets possessed 1,300 times as much uranium per unit surface as is present on the earth. This, however, was not suggested as a serious explanation, as some appear to have thought. Another alternative explanation was departure from black-body radiation, made some two years later, but he does not consider that this is the correct one. He now suggests that if the surface temperature of Jupiter is about 150° absolute and we allow for solar radiation, the planet would have had time to lose 5,000 calories per gram—not an unreasonable amount. With suitable internal conditions the original heat may explain the difference between the observed and calculated radiations. Dealing with the thick ice layer, he does not consider that this implies cold interior conditions, because if the temperature gradient fell below some degrees per kilometre, convection would cease, cooling would be negligible, and a high central temperature would be possible. Dr. Jeffreys also attaches some importance to Wildt's suggestion that the ice would be in the form of Bridgman's high-pressure modification, Ice vi, which can exist at fairly high temperatures.

Teaching of Technical Optics

THE teaching of optics may be divided into four sections; (1) physical optics; (2) optical computation and design; (3) ophthalmic optics; (4) practical optics—glass grinding and polishing.

Physical Optics. The first of these sections is included to a greater or less extent in the teaching of physics in nearly all schools, universities and technical colleges. As 'light' it is included among the subjects that may be offered in the school certificate and matriculation examinations. To more advanced stages it is treated in the courses for the science degree and for the honours examinations in physics at the universities. All these courses are so well known that they need be no further described.

Optical Computation and Design. The second section is an exceedingly important one, as upon the ability to carry this out depends our future progress in the construction of new forms of instruments for surveying, astronomy, gunnery (including such things as range-finding and air defence), photography and microscopy. The actual number of men required for these computations is not large—indeed it is exceedingly small in comparison with the numbers of engineers or chemists for which there is a demand; their importance, however, is not to be measured by their numbers but by the value to the nation of the work they do. The demand for such men has only gradually arisen in (say) the last fifty years. Until then, lenses both for the microscope and for photography had to a large extent been devised and produced by methods of trial and error by practical men, who had only a general acquaintance with optical principles; their calculations were mostly concerned with first-order quantities, and their corrections were the result of their own long experience of the results of changing one or other of the surfaces. This experience in the hands of such men as Andrew Ross and Tom Powell resulted in the production of lenses of excellent performance, but each lens had to be individually tested and adjusted. Then such computers as Schroeder, Hasselkus, Conrady, Booth, Aldis and Dennis Taylor in Great Britain, and Abbe, Rudolf, Goerz and others abroad, showed that there were great possibilities of improvement in the design of lens systems by the application of the theoretical work of Coddington, Seidel and others, and by the systematic computation of the paths of rays through a lens system. As a result, such firms as Zeiss now employ men who spend their whole time in the computation of lenses for optical instruments of all kinds.

The sudden large demand for optical instruments caused by the Great War and by the closure of the foreign supply of such instruments, made it imperative that special courses of training should be provided. Courses were already in existence at the Northampton Institute, set up first by Dr. C. V. Drysdale and later carried on under S. D. Chalmers and since his death in 1919 by H. H. Emsley, but these classes were sparsely attended and did not carry their students very far. A special Department of Technical Optics was therefore established at the Imperial College of Science under Prof. Frederick J. Cheshire with Prof. A. E. Conrady in the chair of optical designing and computing and with L. C. Martin as lecturer. Somewhat later, Prof. A. F. C. Pollard was appointed to the chair of mechanical design of optical instruments. In the first few sessions, the demand for trained computers made the classes abnormally large, but since then they have averaged an output of some half-dozen a year. They cannot expect to be larger, as the number of firms requiring such men is necessarily small; for example, in Great Britain there are only four firms making microscopes—Baker, Beck, Swift and Watson, and four making photographic lenses—Cooke, Dallmeyer, Ross and Taylor, Taylor and Hobson. To these must of course be added firms making surveying, navigating and astronomical instruments, and the army and navy have their own staffs for the design of the special instruments required for warfare; but when allowance is made for all these the total numbers still remain comparatively small, though nevertheless of exceeding importance.

The course at the Imperial College is a two-year one, usually taken as by post-graduates. It includes the theory, design and testing of the fundamental optical systems from both the optical and the mechanical points of view with practical work in all branches. Since their establishment, more than six hundred students have entered for these courses and must have proved of very great value to the industry. The research work of the College, which has been carried on both by students who have continued on after the completion of their course and by the members of the staff, has covered a wide field. Of great importance were Conrady's investigations into the tolerances allowable in an optical system (published in the *Monthly Notices of the Royal Astronomical Society* and later embodied in his "Applied Optics and Optical Design"). Other papers, on ultra-violet transmission of materials and the ultra-violet microscope, the electron microscope, on colour vision and colorimetry and on similar subjects amount in all to more than a hundred and fifty—no inconsiderable output for one department in a comparatively short period.

Some small amount of similar work has been done at both the Northampton Polytechnic Institute, London, E.C.1, and the School of Technology in Manchester, but more in the way of individual work by advanced students and by research than as systematic training, as it has not been worth while to run special classes for the small number of students who wished to attend in any one year.

Ophthalmic Optics. In the third section of optical teaching, ophthalmic optics, there are much larger numbers of students. For these, special examinations were set up by the British Optical Association in 1895 and by the Spectacle Makers Company a year or two later. Before entering for the examinations of the former body, students must have passed a matriculation examination or its equivalent; for the latter they have to sit for a preliminary examination in similar subjects. For the certificates of both bodies the students have to pass in elementary optics; the general structure and functioning of the eye; practical sight testing for the prescription of spectacles; and in workshop practice—lens finishing and mounting and frame making and bending. In order to ensure satisfactory training for the examination, the B.O.A. has 'recognized' certain schools which have been inspected to ascertain that their equipment, staffing, and courses are satisfactory. These schools are mostly in the technical institutes in such towns as Manchester, Edinburgh, Glasgow, Bradford, Cardiff, etc. The largest classes are those at the Northampton Institute, London, where last session more than two hundred and thirty attended organized courses in addition to some sixty who took special courses or individual classes in optics. In Manchester in the same session twelve students were taking full-time courses and about forty were taking part-time courses for these examinations. In the other schools the numbers are of the order of a dozen students in the session. In addition to the optical training in these schools, arrangements are made in all cases for the students to attend some form of hospital course in order to enable them to recognize diseases of the eye, to ensure that patients so suffering shall be sent to obtain proper treatment.

Practical Optics. The fourth section of optical training, practical optics, is provided to a limited extent at all the 'recognized' schools, since it is included in the training of the sight-testing optician, who is expected to be able to grind, polish and edge a lens for a spectacle frame; but it is also arranged as an independent course both at the Northampton Institute and at the Manchester School of Technology. These special courses are planned for workers in optical factories; the students attend on three evenings a week for instruction in drawing, in optical calculations, and in actual lens- and prism-grinding and polishing. The industry so far does not seem to have appreciated the potential value of these classes, as there were less than ten students at either of the schools last session. In spite of the large use of machinery for the grinding and polishing of lenses and prisms, the very exact workmanship required in some cases (roof-prisms, for example, have to be worked to an angle which is correct within two seconds of arc) still necessitates hand finishing; for this and similar work, as well as to enable the men to use the machines in a more intelligent and less 'rule-of-thumb' manner, such classes should surely be of very great value.

Inauguration of the German State Council for Research

In March of last year, the foundation of a new State Council for Research ("Reichsforschungsrat") was announced in Germany by the Minister of Education, Herr Rust. Within ten weeks the fourteen departments of the research organization were formed. In December last a handsomely printed quarto publication describing the Council and its purposes was issued with No. 23 for the year 1937 of the Official Gazette of the German Ministry of Learning, Training and National Education (Amstblatt der Reichs-Ministeriums fur Wissenschaft, Erziehung und Volksbildung). It is entitled "A Celebration of German Learning" (Ein Ehrentag der deutschen Wissenschaft, 25 Mai 1937).

The publication sets out the system on which research is to be organized and the principles on which it is conducted in the Third Reich. It is illustrated with scenes of the inaugural ceremony and with large portraits of the Fuhrer, the Minister of Education, the president of the new Council, Artillery-General Professor Dr. K. Becker, his acting deputy, the vice-president, Dr. O. Wacker, and the directors of the various departments. Fourteen of these departments, all of a definitely technical character, have been established. The speeches of Herr Rust and of Prof. Becker are set out in large type and are followed by detailed records of the career of each director of a department.

In his address, Herr Rust directed attention to his ready action and indicated the need for the establishment of the Council. "The Council," he said, "is initiated at a moment when the German people is preparing, in a manner hitherto unprecedented and by an unexampled expenditure of its utmost effort, to win its rightful foundations of existence, independent of its environment. . . . Not long ago many of us felt that learning (*Wissenschaft*) was too aloof from the great decisions of our time to co-operate in the great struggle of the German people. But the course of German history has itself brought this idyllic attitude to an end and with it has ended also certain idyllic forms of scientific work. The Nazi Revolution summoned science to the decisive battle."

Herr Rust then turned to the question of the freedom of science and of learning: "Complete freedom of opinion and judgment," he said, "are not marks of a truly free science, but rather of an estrangement of the spirit from the eternal forces of Nature and of history. . . . Freedom is assured to science neither by its abstractness nor by its independence of current events. . . . It is rather the hopes of the German people and of the Nazi State in the share of science in the Four Year Plan . . . that give proof of the recognition of the freedom of science.

"If the Nazi State calls on German science to co-operate in the Four Year Plan, it is not because it anticipates the findings of science but because the first task of science will be to give us those materials which Nature has denied us. Such a task can only be accomplished by free science. For science is unfree if her findings be dictated by an unscientific force, but she is free if she sovereignly masters those problems which are posed to her by life. . . . With the foundation of this Council no new principle of scientific behaviour is introduced. . . . What is new is the determinate and planned co-operation of technology and of science for the self-sufficiency of the German economy."

The president of the Council, General Becker, spoke of the reduction in number of the independent centres of research in Germany with the object of concentrating research on more immediate ends. He then turned to consider the way in which the new Council would further the unification of research on methods of preparing raw materials and on their employment. Here, he pointed out, a special position was occupied by the Kaiser Wilhelm Gesellschaft zur Förderung der Wissenschaften.

"The status of the Kaiser Wilhelm Gesellschaft," he said, "will not be disturbed by the new process of organization. Those in authority regard its maintenance as necessary not only because of the respect which it enjoys abroad but also for the purpose of linking research with industry. The necessary cooperation between the State Council for Research and the Kaiser Wilhelm Gesellschaft is for the present guaranteed; first, by the common supervision of both bodies by the Reichsminster (Herr Rust), secondly, by the appointment of the directors of two of the Kaiser Wilhelm Institutes as heads of Departments of the State Council for Research, and finally by my own membership of the Senate of the Kaiser Wilhelm Gesellschaft. Later it will be essential, by suitable measures, to bring the directors of all the Kaiser Wilhelm Institutes into closer relations with the State Council for Research. The Ministerial decree founding the Council," he added, "designates the furtherance of the Four Year Plan as one of the Council's most important tasks."

The careers of the heads of all departments of the new Council are set forth in the publication, those of the president and vice-president being stated as follows:

"*Artillery-General Professor Karl Becker*. Born 1879. From 1900 Artillery Officer. 1906–14 in the Military Technical Academy and active as referee in ballistics. 1914–16 on active service in charge of a 42 cm. battery and then until the end of the War ballistic expert of the Artillery Investigation Commission. From 1919, ballistic expert in the Armaments Office and from 1926 director of its Projectiles and Munitions Department. Since 1932, as director of the Munitions Office Investigation Committee, he has been responsible for the entire technical developments of the Army. In 1933 he became professor ordinarius of military technics, physics and ballistics at the Technische Hochschule in Berlin."

"*Staatsminister Dr. Otto Wacker*. Vice-president of the State Council of Research. Head of the office for Learning (*Wissenschaft*) in the Ministry of Learning, Training and National Education. Born 1899. During the War he was a 'front fighter' on the western front. After the War he studied architecture at the Technische Hochschule at Karlsruhe. Since 1925 he has studied German literature and history at Freiburg, where he took his doctorate. During the revolutionary period he became a district leader (*Kreisleiter*). He also wrote for the Baden journal *Der Führer*. In 1933 he became *Kultus* and Education Minister of Baden. With the nationalization of justice in 1934, he became Minister of Justice for Baden. He is also an SS Commander (*Oberführer*)."

The fourteen departments already organized by the Council are as follows: (1) Physics, including mathematics, astronomy and meteorology; (2) Chemistry and physical chemistry, under the direction of General Becker himself; (3) Power materials; (4) Organic industrial materials, artificial products, rubber, textiles, fats, cellulose; (5) Non-ferrous metals; (6) Geology, including mineralogy and geophysics; (7) Agriculture and general biology, including zoology and botany; (8) Forestry and timber research; (9) Military science and technics, under General Becker himself; (10) Electro-technics; (11) Mining and smelting; (12) Iron and steel; (13) Medicine, including race research and race biology; (14) Military medicine.

Medical Research in Canada

Medical Research Committee

A COMMITTEE to study the organization of medical research in Canada has been appointed by the National Research Council. This action was taken on the recommendation of a nationwide conference on medical research held in Ottawa recently, which was attended by representatives of all the medical schools, organizations and institutions concerned in medical research, including the provincial departments of health, the Department of Pensions and National Health, and the National Research Council. Sir Frederick Banting has been appointed chairman of the new committee. The president of the National Research Council, the deputy minister of the Department of Pensions and National Health, the president of the Canadian Medical Association, and the president of the Royal College of Physicians and Surgeons of Canada are to be *ex-officio* members of the committee. To complete the personnel of the committee invitations have been extended to twelve distinguished members of the medical profession who have a comprehensive knowledge of Canada's requirements in medical research.

It has been suggested by many members of the medical profession that the formation of this committee on medical research under the National Research Council might well be a first step towards the formation of a medical research council for Canada similar to that which exists in Great Britain. Commenting on this suggestion, Major-General McNaughton, president of the National Research Council, speaking at the conference, said that "the National Research Council is approaching the problem of organization of medical research at present as a preliminary measure only. When a purely medical research council becomes necessary, there will be no opposition whatever from the National Research Council. In fact, the National Research Council will give every assistance possible in order to help a movement that in the opinion of the Council is very important for the welfare of the people of Canada."

The immediate purpose of the committee is defined in the terms of reference, which are: (*a*) to receive suggestions for requirements in respect of medical research and in matters related thereto; (*b*) to consider by whom the investigations required can best be carried out and to make proposals accordingly; (*c*) to correlate the information when secured and to make it available to those concerned; (*d*) to do such other things as the committee may deem advisable to promote medical research in Canada.

The conference agreed that the scope of the new committee's activities should not be limited to particular subjects, but that it should be empowered to investigate the whole field of medical research in Canada. One of the first steps to be taken by the committee will be to make a survey of the work in progress at various centres to determine how the activities of the various institutions concerned may be developed to the best possible advantage.

A remarkable record of individual research achievements was revealed in the prepared statements presented at the conference, but the need of bringing the available information together through a central body which could then make it more readily accessible to all concerned was stressed by nearly every speaker. The new committee undertakes its task with the full support and under the direct leadership of the medical profession as a whole in Canada. Results of far-reaching importance are expected in the planning and co-ordination of medical research that will be possible through this new committee. Better dissemination of information regarding the multitude of projects that are being carried on by skilled workers in the hospitals and laboratories of the Dominion will greatly enhance the opportunities of the research workers to make their efforts count.

Progress in Road Research*

ONE of the interesting features of the report of the Road Research Board (director of research, Dr. R. E. Stradling) recently issued by the Department of Scientific and Industrial Research is that which concerns the method of studying the problem of skidding by means of texture prints. These are obtained by inking a portion of the actual road surface and rolling over it a perfectly smooth tyre which then impresses on a sheet of paper an exact record of this portion of the road surface. The object is to study the texture of the surface of a road in order to ascertain its relation to the skidding resistance of the road and to its wearing properties.

The importance of the method can be understood from the statement made in the report that the skidding characteristics of road surfaces are largely determined by the total area of contact between tyre and road and by the number of individual isolated areas of contact into which the total area is divided. In order that, when the road is wet, the liquid on it can escape as the tyre rolls over the road, these small areas of actual contact must be surrounded by channels of adequate size. If the channels are too small, these small areas of contact will, in effect, be merged into one another and the surface will behave as if quite smooth. "An examination of texture prints taken from roads known to be slippery has shown", says the report, "that on these the tyre makes contact with the road over almost the entire area of the ellipse of contact while the number of individual contacts in this area is small". On the other hand, where the sideway force coefficient is high, the proportionate area of actual contact is found to be less while the number of individual areas of contact is much higher. The same is regarded as true of tyre-tread patterns.

In two other directions, the road texture print is an aid to the study of surface problems. By their means the seasonal changes in the slipperiness of roads are being more closely investigated. These, it is believed, depend largely on changes of the surface texture. Then, again, apart from the question of slipperiness, a series of prints is of value in exhibiting the progressive wear of a road surface and of enabling this and other surface changes to be recorded and followed.

The motor-cycle and side-car equipment described in previous reports continues to be employed on skidding tests and is noted as having been employed on surfaces prepared of cast-iron blocks, ordinary wood blocks and special blocks. A sharp fall in the value of the sideway force coefficient as from dry to wet conditions is very noticeable in the results. The higher powered machine now available permits of tests at speeds from 30 to 50 miles an hour, and it would appear that while, on most surfaces, the coefficient tends to reach a steady value in this range, on some there are indications of a continued fall and therefore of increased risk of skidding.

Specimens of mud from surfaces giving low skid coefficients are being studied and their lubricating properties compared with those of water in order to determine to what extent this agency affects slipperiness. The report briefly discusses the question whether mud films on a road during a fog produce a specially slippery surface, and the conclusion tentatively reached is that, from the several points of view quoted, the tendency is towards increased slipperiness.

Tests of road roughness by the special vehicle designed for the purpose and capable of detecting and recording irregularities of more than one fifth of an inch and of integrating them, show a total irregularity, on the best roads, of 75–85 inches a mile. Main roads commonly give 100–250 inches, and very rough roads 500–800 inches a mile.

In investigations on the durability of road construction by means of the full-size lorry driven round a track of 55 ft. radius, experience indicates the desirability of correlating these trials more closely to actual road conditions. In conjunction with a traffic census, records of the periods of wetness and of dryness will afford valuable information. Instruments have been devised for this purpose, the method employed to detect whether the road is wet or dry depending on the fact that the electrical resistance of the film of moisture on the road, measured between two contact strips 3 ft. long and 18 inches apart, is of the order of one fifth megohm when the road is wet, and some 50 megohms when visibly dry.

Other lines of investigation include the impact forces to which traffic subjects a road, the causes of failure of embankments and cuttings in wet seasons, tests of road materials and experiments on the aggregate vibration method of concrete control. An extensive trial of this method is being made by the County Engineer of Surrey in the construction of the Mickleham By-Pass Road.

* Department of Scientific and Industrial Research. Report of the Road Research Board, with the Report of the Director of Road Research, for the Year ended 31st March, 1937. Pp. viii+120. (London: H.M. Stationery Office, 1937.) 3s. net.

Water and the Plant

PROF. E. J. SALISBURY delivered the Masters Lectures of the Royal Horticultural Society in March of last year. He spoke on "The Plant and its Water Supply", and the text is now published in the Society's *Journal* (62, Pts. 10 and 11, Oct. and Nov. 1937). It provides a synopsis of present-day knowledge which should be in the hands of every teacher and research worker in botany.

Prof. Salisbury ministered to the modern necessity for defining what is meant by water, for he considered some of the botanical implications of heavy water. A plant does not have a uniform water requirement throughout its period of growth, and the work of B. N. and B. R. Singh was quoted to show that seedlings and plants about to flower have greater demands than at other stages. Soil conditions naturally play a large part in the supply of water, and the physical forces which are active therein were reviewed in a succinct manner. Recent work upon the extent of root systems, the suction pressures required to transfer water from the soil to the plant, the appearance of osmotic gradients within the root and shoot, the numbers and behaviour of stomata, and the occurrence of hydathodes and nectaries, was marshalled to provide a basis for estimation of a plant's balance of water.

Several external factors may affect these processes. The root system may be diminished by competition or lack of phosphate in the soil, and shoot development is dependent upon proper extension of the root. The intake of sufficient mineral matter and of the rarer essential elements is also conditional upon an adequate area of absorption. It is interesting to note that gold is now enumerated among the elements present in small quantities in the tissues of some plants. It is found in the ash of *Equisetum arvense*, but not in amount sufficient "either to justify its cultivation, or even compensate us for its presence". Plants may also take in some water through the leaves, and the recovery of wilted shoots during the night is probably due very largely to this agency.

The mechanics of water transfer along the stem was also passed under review by Prof. Salisbury. Rates and pressures of the transpiration stream were enumerated. Investigations by Keinholz and by McDougall seem to show that a woody tree is not a rigid system, for the trunk contracts slightly during the day, and recovers at night.

The numbers of stomata upon the leaf of a plant may vary with soil conditions, being crowded when the plant grows in a dry situation, and sparser under wet conditions. Some plants grow better in dry air, while others flourish more in a moist atmosphere. The rate of water loss also depends upon the difference in temperature between the leaf and the surrounding air, whilst wind, of course, increases transpiration.

One cannot escape the conclusion, on reading Prof. Salisbury's lecture, that botanical research owes a great deal to the simplest methods. Measurements of temperature, humidity, water contents and organic matter contents, leaf areas and root lengths, contribute to a very convincing philosophy of the water relations of a plant, and also provide much practical knowledge which can be used directly by the gardener.

Telegraphy and Telephony

Progress in the General Post Office

AT the Institution of Civil Engineers on January 11, Sir George Lee, engineer-in-chief to the Post Office, read an instructive paper on recent and future developments in telephony and telegraphy and on the conveyor and machine systems in postal work. The aim of the developments is reduction of costs or higher precision in transmission. The change in the increase in the number of telephones from 73,000 per annum in 1931, to 250,000 per annum in 1937, and the 50 per cent increase in the traffic in telegraphy due to the new tariffs, shows that such steps are desirable.

It was pointed out that by carrier-cables the speed of transmission in telephony has been increased from about 20,000 miles per second to six times that amount. The use of these cables also reduces the difficulties met with owing to the fact that waves of different frequencies travel with different velocities. It is fortunate that the ear is very accommodating both for electric wave 'echoes' and 'phase delay'. It is interesting to find that the beams of light which constitute a television picture, in order to be portrayed accurately and quickly, require, at the present time, a band width of 1,600,000 cycles, whilst commercial telephony only requires 2,400. Circuits for music require 9,000. Thus the new 'coaxial' cable is expected to carry 400 telephone conversations simultaneously, although it only provides one television channel.

Sir George referred to radio telephone communications by the use of ultra-short waves. Examples were given of commercial communications within the optical range, in the radio telephone system across the North Channel between Scotland and Northern Ireland. This is done by using two stations well above sea-level. A distance of approximately 36 miles is traversed, the path being entirely optical. As an example of a service working over a non-optical range, the radio telephone service between England and Guernsey was cited. It was attempted at first to cover a range of 105 miles, the optical range being only 45 miles. With this arrangement it was found that as late autumn changed into winter, the received energy was only about one thousandth of that received during the summer. A change in the stations selected reduced the distance to 85 miles; this worked satisfactorily, the working range being 1·73 times the optical distance.

Science News a Century Ago

Human Temperature in Different Climates

AT a meeting of the Academy of Sciences on April 9, 1838, reported in the *Gazette Médicale de Paris* of April 21, MM. Eydoux and Souleyet reported their observations on the men belonging to the crew of the *Bonite* of different ages and temperaments but always leading the same kind of life and engaged in much the same kind of occupations. Their observations were carried on every day at the same time (3 p.m.) from their arrival at Rio de Janeiro until their return to France. These observations, which amounted to more than a thousand, showed that human temperature rises and falls at the same time as the external temperature, though much less rapidly, as it is easy to imagine. It falls rather slowly on passing from a hot to a cold country, but after leaving a cold region for a tropical one it rises much more rapidly. This upward or downward movement is more or less marked according to the individual, but the extremes are fairly close to one another, and the average of the differences observed in the temperature of the human body for a difference of 40° C. in the temperature of the external air was only about a degree in the men under observation.

The Royal Astronomical Society

AT a meeting of the Royal Astronomical Society on April 13, 1838, several communications were made. The first of these was "On the Correction of the Mean Distance, Eccentricity, Epoch and Longitude of the Aphelion of the Orbit of Venus, by Errors of Heliocentric Longitude derived from the Cambridge Observations of the Years 1833, 1834 and 1835 and the Greenwich Observations of 1836". The author of this paper was the Rev. Robert Main (1808–78) who had become chief assistant at Greenwich in 1835 and was afterwards Radcliffe observer at Oxford.

Another paper, entitled "Times of Emerson of the first and second Satellites of Jupiter observed at Greenwich Hospital School, April 9, 1838", was by Edward Riddle (1788–1854) who was mathematical master at the School from 1821 until 1851. "These phenomena," said Riddle, "deserve notice and are here recorded, merely from their happening within so short a time of each other, and from their having been observed earlier in the evening than the superintendent of the *Nautical Almanac* anticipated that they could be seen with advantage in this neighbourhood."

German Scientific Periodicals

THE editor of the *Athenæum* had apparently asked a correspondent in Germany to give a review of the progress of art and science in that country, and accordingly a communication was sent from Dresden which was printed in the journal on April 14, 1838. "Your wishes", the writer began, "are easier expressed than complied with; however, I will do my best to give you a sketch of the intellectual world of Germany. . . . In no part of Europe is the number of periodicals devoted to science, art and literature, so great as in Germany. . . . In the scientific and medical journals, of which about eighty exist in Germany (forty-one being exclusively devoted to physiology and medicine) many subjects of importance are under consideration and discussion. Animal magnetism, somnambulism, and even the histories of people possessed with devils occupy many pens . . . the works on animal magnetism, which have lately appeared from the pens of Professor Hensler and Dr. Bork . . . are reviewed in Gersdorf's Repetorium and other journals. Dr. Bork asserts that during the last nine years he has cured no less than two thousand diseases through the influence of animal magnetism. In the writings of two other medical men, the greater number of illnesses, particularly of married people, are attributed to disharmony in the magnetic influences; and however absurd such opinions may be thought in England, it is beyond question that many educated Germans have faith in them. . . . Another therapeutic novelty . . . is the *cold water* system. . . . The press is continually producing works advocating cold water, internally and externally, as the grand remedy for all disorders."

. . . . .

"A periodical of somewhat higher pretensions than any of the preceding is the 'German Quarterly' just published by Cotta, of Stuttgart. . . . This work is to occupy new ground, and supply a void long felt to exist. A point of union was wanting in Germany, where new discoveries and their practical utility . . . could be immediately discussed and appreciated, by men of all parties, distinguished for science and general attainments. Germany may boast of a conscientious cultivation of the sciences and of its honorable acknowledgement of the merits of foreigners; but many first rate men have often been thrown back on themselves, or confined to a narrow circle, though capable of imparting valuable information to society, from the want of such a work. . . . No man can find time to hunt after all that he may desire to be informed of, if scattered abroad in numberless periodicals; and few public libraries, much less individuals, have even the means at command to purchase all that are published. And yet the basis of knowledge is wasted, and the capacity to appreciate it greater, in Germany than in the surrounding countries. The German Quarterly is intended to collect together whatever is best and most important in all branches of knowledge, that they may gain general appreciation and be brought home as far as possible to the business and bosoms of men in our everyday life. . . ."

A Life-Saving Rocket Apparatus

THE *Mechanics' Magazine* of April 14, 1838, quoting from the *Silurian*, said: "A Mr. Gyngell made experiments on the Green near Brecon, with some rockets of his invention for communicating with stranded vessels. He discharged several rockets of different weights. The rope was coiled on a cone formed of light rails of wood, and was carried out the distance of from 3 to 5 hundred yards according to the size of the rocket attached to it. . . . Mr. Boyers, of Swansea, in a letter on this subject that we inserted a few weeks since, remarks that if rockets could have been obtained at the time of the wreck of the Killarney steamer, a number of lives might have been saved and the survivors would have been delivered from their dreadful sufferings. . . . It is very seldom that an instance occurs of a vessel striking on a lee shore a greater distance than a quarter of a mile from the land. We need hardly point out the utility of the rocket in such cases, and we hope ere long no vessel will leave port without being provided with this simple and cheap apparatus."

University Events

Aberdeen.—The honorary degree of LL.D. was conferred on Dr. E. J. Butler, secretary to the Agricultural Research Council, and on Dr. G. Dahlberg, director of the Institute of Medical Genetics, Uppsala, among others, on March 30. The ordinary degree of D.Sc. was conferred on Dr. D. Robertson, for a thesis entitled "Studies on the Internal Parasites of Sheep in Scotland and the Importance of Nutrition in Regard to their Control."

Cambridge.—The adjudicators consider that the following essays submitted by candidates for the Smith's Prizes and Rayleigh Prizes are of distinction: F. Hoyle, of Emmanuel College, "Beta-Disintegration"; G. L. Clark, of Trinity College, "The Relativity Theory of Gravitation"; G. S. Rushbrooke, of St. John's College, "Strictly-regular Solutions"; A. L. Yoxall, of Sidney Sussex College, "Systems of Equivalence and their Applications to the Geometry of Algebraic Varieties". The Smith's Prizes are awarded to F. Hoyle, of Emmanuel College and A. L. Yoxall, of Sidney Sussex College. Rayleigh Prizes are awarded to G. L. Clark, of Trinity College and G. S. Rushbrooke, of St. John's College.

The General Board recommends: (*a*) that the following additional University teaching offices be established: A University lectureship in the Faculty of Economics and Politics; two University demonstratorships in the Department of Engineering; (*b*) that a third assistant directorship of research in colloid science be established and that the General Board be authorized to appoint Dr. H. W. Melville to this post for five years; (*c*) that a post of assistant in statistical research be established; (*d*) that three posts of assistant in research in medicine be established from July 1, and that appointments to these posts be made by the Appointments Committee of the Faculty of Medicine, with the approval of the General Board, each for a period not exceeding five years, or for so long as the Rockefeller Foundation continues the grant to the University for this purpose, whichever period is the shorter.

The Board of Research Studies has approved Dr. F. P. Bowden, of Gonville and Caius College, for the degree of Sc.D.

London.—Lieut.-Colonel H. E. Shortt has been appointed, as from April 1, to the University readership in medical parasitology tenable at the London School of Hygiene and Tropical Medicine. Since 1934 he has been director of the King Institute of Preventive Medicine, Madras.

Societies and Academies

Paris

Academy of Sciences, February 7 (*C.R.*, 206, 385–464).

Gaston Julia: The inversion of the linear operators of Hilbertian space.

Lucien Cayeux: The brechoid structure of chalk containing phosphates of the North of France, and its multiple origins.

Charles Achard, Augustin Boutaric and Mme. Madeleine Roy: Viscosimetric researches on serums and solutions of their proteins separated by the cold acetone method.

Pierre Lejay: Application of the inverted elastic pendulum to levelling the axes of astronomical instruments. This method possesses some advantages over the usual liquid level. It is much more rapid and rather more accurate.

Henri Eyraud: Some laws of errors in two dimensions.

Gustave Malécot: The Mendelian chances and the correlations of heredity.

Stanislas Golab: The function representing the distance of a variable point to a fixed ensemble.

Rodolphe Henri Germay: The decomposition into primary factors of certain uniform functions.

Dragoslav S. Mitrinivitch: Theorems relating to the differential equation of Riccati.

Robert Ballieu: Functions locally univalent in the unit-circle.

Chi-Tai Chuang: A criterion of quasi-normal family and on Schottky's theorem.

Joseph Peres and Lucien Malavard: Analogical realizations of flow with jet lines.

Pierre Clerget and Raymond Marchal: The working of injection motors and igniting by compression in a rarefied atmosphere. The motor, with double injection, was fitted with mechanical compressor giving an admission pressure of 760 mm. at a height of 2,700 metres. An aeroplane driven by this motor climbed to a height of 7,650 m. without the controls being affected.

Godofredo Garcia and Alfred Rosenblatt: Stokes's formula in the theory of gravity.

Gleb Wataghin: The theory of neutrinos.

Paul Ehrenfest: Two negatives of penetrating cosmic rays obtained in the Bellevue magnetic field (10,000–15,000 gauss) and on the existence of a heavy particle.

Mathieu Dobine: A possible method of determination of the true adsorption of the solvent and of the dissolved body in concentrated solutions.

Georges Carpéni: Electrometry and ultra-violet spectrography of rhodizonic acid. Remarks on titration with iodine.

Georges Wolf: A method of determining the metals of the alkaline earths. The method is based on the pressure of carbon dioxide obtained by heating a mixture of the three carbonates in a vacuum at temperatures between 630° C. and 840° C.

Fernando Gonzàlès Nuñez and Emilo Figueroa: Preparation and study of vanadyl bromide.

Mlle. Yvonne Garreau: Some addition compounds of pyrocatechol.

Mme. Elisabeth Jérémine: The lherzolites in the course of serpentinization in the Lorraine Vosges.

François Kraut and André Vatan: The origin of the clay rocks of the neighbourhood of Confolens (Charente) attributed to the siderolithic. These clays are not, as has been supposed hitherto, siderolithic sediments, but have been formed where they are found.

Arnold Bersier: The subsidence in the molassic pre-fosse of the Alps.

René Bernard: The observation of a new fluorescence phenomenon in the upper atmosphere. The presence and intensity variations of the radiation λ 5893 A. in the light of the sky at twilight.

Jacques Bardet, Arakel Tchakirian and Mlle. Raymonde Lagrange: The spectrographic search for traces of elements in sea water. Various precipitates were formed in sea water (60 litres) and examined spectroscopically. By this method all the elements detected by other workers, with the exception of nickel and tungsten, have been found, and arsenic and gallium, not previously notified, were added to the list. Gold was not found, and there seems reason to suppose that gold is irregularly distributed in sea water.

Tien Kiu : Atmospheric absorption and molecular diffusion according to the measurements of the Smithsonian Institution at Montezuma.

Philippe Hagene : The influence of the solvent and of the concentration on the velocity of penetration of thymol into the internal epidermal cells of the fleshy leaves of the onion bulb.

Roger Gautheret : Researches on the culture of fragments of tubercles of the carrot.

Maurice Bouchet, Antoine Jullien, Daniel Vincent and Mlle. Madeleine Vuillet : The diffusion of acetylcholine starting with the heart of *Helix pomatia*. In *Helix pomatia* a fraction of the intramyocardiac acetylcholine is diffusible into the surrounding medium : the concentration of the medium in this substance increases with the time, reaching a certain equilibrium after some hours. The quantity set free amounts to approximately one eighth of the total stock of acetylcholine.

Antoine Magnan, Charles Perrilliat-Botonet and Henry Girerd : Attempts at simultaneous cinematographic recording in three perpendicular directions, two by two, of the flow of air around a bird in flight.

Prague

Czech Academy of Sciences and Arts

May 28, 1937.

J. Milbauer : Colloidal and pure carbon. Colloidal carbon was prepared by the action of sulphuric acid on acetylene at 200° C. After centrifuging and washing, purest carbon was obtained, of a brownish black colour. Pure carbon was also obtained by using sugar instead of acetylene.

R. Rost : The minerals in burning waste heaps in the Kladno district.

A. Orlov : The first discovery of bauxites in Czechoslovakia.

E. Kodíček and J. Joachim : The quantity of vitamin C in the organs of rats affected by vitaminose B.

T. Buday : Geological conditions in the surroundings of Šahy, in southern Slovakia.

October 22, 1937.

K. Domin : *Lycopodium Issleri* Rouy in Czechoslovakia and the variability of the native *Lycopodium* of the section *Heterophylla* Spring.

B. Hejda and F. Procházka : Glutathione in the blood, and its significance in metabolism.

F. Němejc : Palæobotanical studies in travertine sediments near Gánoved and Horky (Poprad, Slovakia).

J. Wolf : The surface relief of human skin. (2) Stratum desquamans epidermis in man.

V. Špalek : The Miocene of Židlochovice, Moravia.

December 10, 1937.

J. Milbauer : A note on the action of permanganate with selenites.

J. Vachtl : A new discovery of carboniferous flora in the Slovakian Ore Mountains.

M. Hampl : The strain and bending of a spherical bottom, effected by uniform radial pressure.

V. Hovorka and V. Sýkora : The β-oxime of isatine, a new reagent for certain metals. (2) Determination of uranium by the β-oxime of isatin.

Washington, D.C.

National Academy of Sciences (*Proc.*, 24, 53–106, Feb. 15).

W. J. Robbins : Organisms requiring vitamin B_1. The fungi examined can be divided into four groups according as they require : (1) the vitamin ; (2) thiazole and pyrimidine (intermediates of the vitamin), or the vitamin ; (3) pyrimidine, both intermediates or the vitamin ; (4) thiazole, both intermediates or the vitamin. Some fungi are unaffected by any of these substances, and others are inhibited.

O. J. Eigsti : Cytological study of colchicine effects in the induction of polyploidy in plants. Solutions of 1 per cent colchicine and upwards are toxic, and even weaker solutions are toxic if treatment is prolonged. Weak solutions produce enlargement of meristematic tissue (root and stem). Individual cells are affected independently of their neighbours. Mitosis proceeds, but spindle and cell-plate formation are inhibited, producing nuclei with double or more times the number of chromosomes.

G. Evelyn Hutchinson : Chemical stratification and lake morphology. The distribution of alkalinity (bicarbonate ion, determined by titration with methyl orange as indicator) in a small lake suggests that the bottom water movements are confined to thin horizontal layers, as suggested by Alsterberg. Certain sudden rises in alkalinity appear to be initiated by temperature minima at the surface.

J. Bonner and D. Bonner : Ascorbic acid and the growth of plant embryos. Embryos of different varieties of peas differ markedly in the amount of ascorbic acid they are able to synthesize from sucrose and also in their response to added ascorbic acid. Varieties which synthesize most respond least (or not at all) to added ascorbic acid, and vice versa.

W. J. V. Osterhout : Potentials in *Halicystis* as affected by non-electrolytes. To study changes in potential difference caused by diluting sea water bathing cells of *Halicystis*, a non-electrolyte should be added to maintain the osmotic pressure of the sea water ; mannite seems to be most suitable.

G. W. Beadle, R. L. Anderson and Jane Maxwell : A comparison of the diffusible substances concerned with eye colour development in *Drosophila*, *Ephestia* and *Habrobracon*.

D. M. Whitaker : Effect of *p*H on the development of ultra-centrifuged *Fucus* eggs. Fertilized eggs centrifuged at 150,000 times gravity and at *p*H 7·9–8·1 formed rhizoids at the centrifugal ends ; at *p*H 5·8–6·1, rhizoids formed at the centripetal ends. The effects may be due to concentration and toxic over-concentration respectively of growth hormone by centrifuging.

Louise Wipf and D. C. Cooper : Chromosome numbers in nodules and roots of red clover, common vetch and garden pea. In each species, a tetraploid number (twice that of ordinary tissue) was found.

G. A. Miller : (1) Groups having a maximum set of independent generators of the same order. (2) Groups having a maximum number set of conjugate independent generators.

R. Courant : Existence of a minimal surface of least area bounded by prescribed Jordan arcs and prescribed surfaces.

F. Bernstein : The continuumproblem.

H. Lewy : Existence of a closed convex surface realizing a given Riemannian metric.

Forthcoming Events

Tuesday, April 12

Quekett Microscopical Club (at 11 Chandos Street, Cavendish Square, W.1), at 7.30.—Prof. F. J. Cole, F.R.S.: "Microscopic Science in Holland in the Seventeenth Century". (Open to the public.)

Wednesday, April 13

Society of Glass Technology (in the University, Sheffield), at 2.—Annual General Meeting.

Faraday Society, April 11–13. General Discussion on "Chemical Reactions involving Solids", to be held in the University of Bristol.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant Engineer in the Roads Department of the Ministry of Transport—The Assistant Secretary, Establishment Department, Ministry of Transport, Metropole Buildings, Northumberland Avenue, W C.2 (April 11).

Civilian Instructor (engineering) for the Royal Army Service Corps Training Centre, Aldershot—The Under-Secretary of State (C.5), War Office, London, S.W.1 (April 11).

Senior Technical Officer at the Air Ministry Headquarters, London—The Secretary, Air Ministry (S.2.d), Adastral House, Kingsway, W.C.2 (April 15).

Scientific Officer in the Air Ministry Research Pool—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (April 15).

Junior Scientific Officers at the Building Research Station, Garston—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (April 19).

Junior Scientific Officers at the National Physical Laboratory, Teddington, Middlesex—The Director (April 19).

Lecturer and Assistant Lecturer in Mechanical Engineering in the Belfast College of Technology—The Director of Education, Victoria Street, Belfast (April 23).

Civilian Education Officer (grade III) in the Royal Air Force Educational Service—The Secretary, Air Ministry (E.S.1.), Adastral House, Kingsway, London, W.C.2 (April 23).

Head of the Civil and Mechanical Engineering Department of the Northampton Polytechnic, St. John Street, London, E.C.1.—The Principal (April 25).

Assistant Lecturer in Statistics in the London School of Economics, Houghton Street, Aldwych, London, W.C.2—The Secretary (April 30).

Assistants (grades II and III) in the department of War Department Chemist—The Under-Secretary of State (C.5), War Office, Whitehall, London, S.W.1 (April 30).

Instructor in Domestic Engineering in the Education Department of the Straits Settlements—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1.

Lecturer (woman) in Hygiene and Biology in the Avery Hill Training College—The Education Officer (H.2/1), County Hall, London, S.E.1.

Assistants (grade III) in the Meterological Office—The Secretary (S.2.A), Air Ministry, Adastral House, Kingsway, W.C.2.

Director of the National Institute of Poultry Husbandry—The Principal, Harper Adams Agricultural College, Newport, Shropshire.

Civil Engineer in the Public Works Department of the Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1.

The Protectorates and the Union in South Africa

NATIVE affairs in the greater part of South Africa, though no longer under the jurisdiction of the British Parliament, continue to be a prominent factor in the relations between Great Britain and the Union. Both inside the British Parliament and without, there is a spirit of watchfulness, which gives close regard not only to any action of the Union Government, but also to the currents of public opinion in South Africa in all matters affecting the present welfare and future development of the native and coloured populations. In questions relating to the inhabitants of the Protectorates and Territories under British administration, in which this body of informed opinion can make its influence effective, its aim is to avoid opening the door to either exploitation or treatment considered detrimental or not in accord with the methods and principles of native administration in the territories, when the inhabitants of these territories cross the Union borders to meet the demand for labour. Hence it is usual for the appearance of the Protectorates on the question paper of the House of Commons to herald a lively and instructive debate.

An important statement in response to questions dealing with the future of the Protectorates was made by Mr. Malcolm MacDonald, H.M. Secretary of State for Dominion Affairs, in the House of Commons on March 29. It contained an explicit reaffirmation of policy, and went on to announce two practical measures, which are to be put into operation forthwith. In the matter of policy, Mr. MacDonald, while recognizing on behalf of the British Government the meaning and intention of the sections of the South Africa Act of 1909 which deal with transfer, also emphasized the binding character of the pledges that transfer to the Union Government would not take place until, on one hand, the wishes of the natives had been most carefully considered, and on the other, the United Kingdom Parliament had been given the fullest opportunity to express its views. In the meantime, he went on to say, a conference is to be appointed consisting of three representatives of the Union Government and the three resident commissioners of the Protectorates. This conference is to study "openings for co-operation between the Union Government and the Administrations in matters affecting the development of the territories, and to consider any matters of joint concern to the Union and the territories". As regards the nature of the inquiries, it was indicated in subsequent debate that they are to be of a technical character, such as the prevention and control of animal diseases, marketing of produce, prevention of bubonic plague, etc.

The second measure is the preparation by the Union Government of a series of memoranda, which as a whole will place before the peoples of the Territories, native and other, a clear picture of the terms on which the transfer of the government should take place. These terms, it was said, would follow closely the provisions of the schedule of the South Africa Act and deal with the conditions of government, the maintenance of tribal institutions, the economic advantages to accrue to the territories and so forth.

Taken at their face value, these two practical measures have much to commend them. In bringing them forward, the British Government has been anxious to further the policy of co-operation adopted three years ago, of which the aim, as stated at the time, was to demonstrate to the peoples of the territories that "the Union

Government are working in concert with the local administrations with a real and generous desire to develop and improve conditions in the territories". The Union Government in dealing with the Protectorates under this arrangement has been as generous in giving financial and other assistance as it has been to South-West Africa; and its attitude merits recognition. The conference which is to be set up should help to alleviate the legitimate grievances of the Union—advanced as one of the reasons for transfer, and indeed one of the strongest—in that the natives of the territories, who are economically dependent upon the Union, are beyond its control in matters in which the welfare of the Union is vitally affected, such as, for example, the control and prevention of cattle and other diseases, labour supply and other technical or difficult questions of a like character.

There was evident anxiety felt in the House of Commons lest the convention should not be sufficiently possessed of the necessary expert knowledge of such subjects, while there was also perturbation because of the fact that the natives are not to be represented. On both counts Mr. MacDonald expressed confidence in the knowledge of the resident commissioners, as well as in their sense of responsibility for the interests of the natives of their respective territories.

Later in the debate, it became abundantly clear that the members of the House also felt considerable apprehension lest acceptance in principle of the preparation of the memoranda—apparently their preparation is already well advanced—should be construed as a pledge of transfer. This elicited the assurance that the memoranda were no more than an intimation of how the Union Government would propose to deal with the matters recited in the schedule of the Act of 1909, and further that they would be issued in a readily accessible form.

At this point it may be regarded as appropriate and, indeed, instructive, to refer to a statement of future native policy which indicates the line of approach of a legislature outside the Union. In laying the foundation stone of the David Livingstone memorial mission school at Ntabasinduna, Mr. Huggins, the Prime Minister of Southern Rhodesia, announced that in the coming year the Government will provide additional advanced training for natives in training schools. At the same time, he foreshadowed a policy of segregation in which the country would be divided up into separate 'white' and 'black' areas. In the black areas the native is to be protected from white competition. In the white areas the native will be allowed to assist, but not to compete with the white man. Native education, he went on to say, would be by missions and not by the State, until natives had a background of Christianity.

Criticism of such a scheme is obviously out of place, until it is possible to see how far the native tribal controls, to which Mr. Huggins referred, are to be retained. It seems illogical to deprecate the effect of white man's law, religion and example, and yet to refuse the facilities for advanced education until a background of Christianity has been acquired.

In fact the trend of anthropological investigation, that is, investigation not only of native thought and institutions in their integrity, but also as they are affected by European culture contacts, now seems to suggest that if tribal controls are to be regarded as of value, and utilized in the moral training of the individual, early education will involve a scientific and objective study of native taboos and institutions. This cannot fairly be asked of a mission, to which education is left without State assistance or control.

If the Union Government, apart from the spur of advantages to accrue to the Union, is urgent for early transfer of the Protectorates out of a desire to help them, the preparation of the memoranda affords an opportunity for approach to the solution of the problem of native development such as has never occurred before in South Africa, free from tradition and prejudice and the preponderating claims for consideration of a white population. It should then be possible by a scientific and dispassionate study of the situation as a whole, to work out a scheme of administration, education and training, not overlooking opportunities for utilizing that training in after-life which would make the disintegration of tribal life, inevitable in the long run, a slow and gradual process, in which a sense of individuality, appropriately and advantageously suppressed in a tribal form of existence, could be built up to fit the native to take his place in a more advanced civilization. It may be recalled that to carry out an ambitious scheme of this nature South Africa has at its service a school of anthropologists, not only well versed in the study of African tribal thought and institutions, but also well trained, as it has already shown by its work, to gauge the trend and effect of cultural modification and contacts among African peoples.

Scientific Thought in Tudor Times and After

(1) Astronomical Thought in Renaissance England:
a Study of the English Scientific Writings from 1500 to 1645. By Francis R. Johnson. Pp. xv + 357. (Baltimore, Md.: Johns Hopkins Press; London: Oxford University Press, 1937.) 15*s*. net.

(2) Johannes Kepler Gesammelte Werke
Herausgegeben im Auftrag der Deutschen Forschungsgemeinschaft und der Bayerischen Akademie der Wissenschaften, unter der Leitung von Walther von Dyck und Max Caspar. Band 3: Astronomia Nova. Herausgegeben von Max Caspar. Pp. 487. (München: C. H. Beck'sche Verlagsbuchhandlung, 1937.) 12 gold marks.

(3) Œuvres complètes de Christiaan Huygens
Publiées par la Société Hollandaise des Sciences. Tome 19: Mécanique théorique et physique de 1666 à 1695; Huygens à l'Académie Royale des Sciences. Pp. iii + 688 + 6 plates. (La Haye: Martinus Nijhoff, 1937.)

THE Middle Ages in England were buried in Bosworth Field. Science in the next two centuries culminates in the age of Newton. Here are parts of the work of two outstanding figures in the second half of that period. The other book which comes under review covers the greater part of the longer interval of time. Perhaps a happier choice might have been found in the limits of the Tudor period itself. The scientific spirit of the seventeenth century is visibly different from that which had prevailed up to the closing years of the sixteenth. It is often startlingly modern. But Mr. Johnson's choice helps, sometimes unconsciously, to lay stress on this contrast.

(1) Mr. Johnson's book is a well-written and, within limits, a scholarly work. It is the more necessary to explain its intention. It describes the scientific, mainly the astronomical, literature of the period. The material is drawn from the English printed books to be found in libraries, particularly the Huntington Library. It is a bibliographical study for use as a background to the more general literature of the times. But references to this great literature are few and mainly incidental. On the other hand, no very satisfactory picture of the scientific history of the time emerges. For that a more intimate knowledge and a stronger sense of proportion would have been required.

The first half-century is pre-Copernican. The infusion of Hellenic culture denoted by the Renaissance is scarcely more important than its immediate diffusion by the printing press. In relation to science the main influences were threefold. That of Aristotle waned almost continuously. The second may perhaps be indicated by the Pythagorean tradition, which continued in force long enough to number Kepler among its adherents. Taken in a broad sense, this includes the work of the Greek mathematicians, and is associated with the Platonists, though the obscurities of the "Timæus" suggest clearly that Plato himself was a very poor geometer. Finally there was the "Almagest", together with the Alfonsine tables. But as there must have been few capable of understanding the nature of Ptolemy's great work, it seems to have been commonly replaced in popular estimation by a wretched Aristotelian travesty. The writings of the Oxford school of the time of Roger Bacon remained available generally in manuscript form only. Still, they were not without effect.

There is evidence that a fairly general interest was taken in England in these various factors from the past in forming a scientific judgment. Then came the "De Revolutionibus", followed by the Prutenic tables of Reinhold. The general views of Copernicus were readily assimilated by Robert Recorde, a fine Greek scholar, textual critic and mathematician. Tables were reproduced by John Feild. But ready as was the response to new ideas, the scientific value of the reaction seems easily over-estimated. When a work of this particular kind is in question there are three distinct elements in the appreciation of it. There is the simple idea, here a heliocentric theory in the vaguest sense, which many people with open minds can understand. A much smaller number can understand the resulting tables and use them. But the number who can penetrate to the inner spirit of the work is always small indeed. In this case the response scarcely went beyond the first class. The Aristotelians remained entrenched. The energies of a most active age in England were otherwise directed. There were no astronomers to make systematic and purposeful observations, and the mathematicians were left without straw to make bricks. The fine sentiments of the period, which are not wanting, rather serve to emphasize its scientific immaturity.

Mr. Johnson has chosen the reaction to the Copernican theory as a touchstone of scientific progress in his period. A truer estimate of that theory seems therefore to be necessary. Now Copernicus was a great man undeniably, and it is right that history should err in its estimates of great men on the side of generosity. But in this case it is not easy to do so without doing injustice to two far greater men, Ptolemy on one side and Kepler on the other. The "De Revolutionibus" is in the strictest sense a derivative work. Stripped of all detail and represented for the popular taste as a heliocentric theory, it is a reincarnation of Aristarchus of Samos, as Robert Recorde observed. With the detail restored, it is a geometrical transformation of the "Almagest" so slavish in its imitation that the claim to be considered a true heliocentric theory must be abandoned. The only true begetter of such a theory was Kepler. Moreover, the period during which the work of Copernicus can be said to have had a scientific, as opposed to a popular or archæological, value, is limited to sixty-six years, 1543–1609, after which it was superseded by the "Astronomia Nova".

It may be well to indicate where the real greatness of Copernicus lay. To the Arabian astronomers belongs the credit of preserving the "Almagest". But their creative powers were limited. The utmost they could do was to use the work, and their highest efforts are embodied in the Alfonsine tables. The first man who could see to the core of the work, understand its mathematical devices and adapt them to another form, was Copernicus. For this all honour is due to him, though the weapon he fashioned, when applied to the computation of an ephemeris, had exactly the same range as Ptolemy's, no more and no less.

When he enters on the seventeenth century and approaches the date of Newton's birth, Mr. Johnson's account seems to become less satisfactory, certainly as a commentary on the true scientific history of the time. The rival theories are now those of Copernicus and Tycho Brahe. The work of Galileo had an immediate popular appeal. Here it may be noted that the fundamental problem of astronomy was ultimately solved without the aid of the telescope. Galileo's more important contribution was made to the foundation of dynamics. But as judged by the material to which Mr. Johnson has had access, the state of the public mind seems to have become more confused on scientific questions than in the previous century. For some reason he is particularly severe on Francis Bacon. Bacon as a man had his faults, no doubt. But in so far as he embodied the philosophical ideas of his time in a supreme degree, Mr. Johnson should surely have found more satisfaction in revealing the background from which they were drawn than in imputing a lack of originality. The estimate of "Baco Verulamius" formed by Huygens was very different.

(2) The first instalment of Kepler's works to be newly published is the third volume of an edition which is destined to supersede that of Frisch (Frankfurt, 1858–71). The "Astronomia Nova" may be counted one of the three greatest works on astronomy, the other two being the "Almagest" and the "Principia". It is impossible, with the volume at hand, to resist quoting the words in which a true heliocentric theory was first stated :

> Ad Physicas vero causas motuum indagandas primus gradus fuit, ut demonstrarem, concursum illum Eccentricorum non alio loco (prope Solem) contingere, quam in ipsissimo centro corporis Solaris, contra quam Copernicus et Braheus crediderant.

And in the margin :

> Primus ad eas gradus factus. In unico centro corporis Solaris concurrere omnium sex Eccentricorum plana.

In a short space it is only possible to allude to one point, but it seems an interesting one. The book when it appeared was far in advance of its age, and few were capable of understanding it In the editorial appendix (p. 459) it is mentioned that twenty-three years after its publication Galileo denied that there was any certain knowledge of the theory of the planets. But this is not all. In a note (xix, p. 258) on the problem of planetary tables, written for the Paris Academy of Sciences in 1667, Huygens shows no greater understanding of the position. The names of other astronomers in the same case are mentioned by Montucla.

In England, events took a different course. In the years 1606–9, Thomas Harriot was in communication with Kepler. The letters are extant and may be the occasion of some future reference when a later volume of this edition appears. This correspondence is mentioned by Mr. Johnson. That Francis Bacon, writing about 1612, betrays an ignorance of Kepler's laws of planetary motion seems scarcely surprising in the circumstances or a fair subject for reproach. But how far bibliography and history can stand apart is illustrated by the fact that no mention is made in Mr. Johnson's book of Jeremiah Horrocks (*d.* 1641). The nearest contact is through Samuel Foster, whose name occurs in a list of Gresham professors of astronomy. Now Foster was in correspondence with Horrocks. The omission can no doubt be justified on technical grounds, but it is fatal to any true picture of the times. For Horrocks, alone of all his contemporaries, had the proper appreciation of what Tycho Brahe and Kepler had done, and his boyish enthusiasm made him a unique figure in the history of science. Dying almost as soon as he had reached his majority, he can stand in the line Kepler—Horrocks—Newton for all time. As Kepler had stated the laws of undisturbed motion, so Horrocks approached the problem of perturbations both in lunar and planetary theory with perfect insight. To a mathematician like Newton the rest was a logical conclusion. Great credit is due to Gilbert as a pioneer in experiment, but some of the deductions drawn from his work on magnetism seem to have been quite illogical and misleading. Here again Horrocks brushed away with effortless ease the magnetic cobwebs which Kepler had picked up from Gilbert.

(3) When vol. 18 of the monumental edition of the works of Huygens appeared, it seemed as if the stream of rich material was at last beginning to show signs of exhaustion The end cannot be far distant. But the latest volume with its admirable editorial notices returns to a level of interest certainly not below the average. It contains the classical "Traité de la Lumière", surely one of the most beautiful memoirs on a physical subject ever written. This alone is enough to give distinction to the volume in which it appears. An antecedent fragment, here reproduced in facsimile, is headed : "'ΕΥΡΗΚΑ 6 Aug. 1677. Causam mirae refractionis in Crystallo Islandica", and the exultation in the discovery of ellipsoidal waves seems entirely justified. Huygens returned from The Hague to Paris in the following year, and the substance of the "Traité" was delivered to the Academy in a series of discourses. Publication was delayed until 1690, with some idea of preparing a Latin text. It would seem that Huygens had less than Kepler's facility in that tongue. A change of fashion was beginning to set in, though the practice survived to the days of Gauss and Bessel.

The fate of Huygens's ideas on physical optics is well known. The interval from Huygens to Fresnel has some analogy to that from Kepler to Newton, and it was even longer. As the failure to appreciate the significance of Kepler's great work has already been noticed, it may be remarked that, after making the personal acquaintance of Newton in 1689, Huygens accepted the theory of elliptic orbits, even for comets.

This volume, which contains the contributions of Huygens as an academician at Paris, covers the whole range of mechanics and physics as now understood. It is a mine of information on the state of science in the latter half of the seventeenth century, and it gives a singularly complete picture of the mind of this great man. The intellectual heir of Descartes, the influences impressed in youth persisted through his life. How they led him, and how far his natural independence triumphed over inherited prejudice, can be studied and fairly seen in this single volume of his works.

H. C. P.

Quantum Theory in Chemistry

Einführung in die Quantenchemie
Von Prof. Dr. Hans Hellmann. Pp. vii + 350. (Leipzig und Wien : Franz Deuticke, 1937.) 20 gold marks.

Dirac has said, "The general theory of quantum mechanics is now almost complete. . . . The underlying physical laws necessary for the mathematical theory of a large part of physics and the whole of chemistry are thus completely known, and the difficulty is only that an exact application of these laws leads to equations much too complicated to be soluble. . . ." How then is it possible to have a quantum chemistry ? Must the chemist for ever wait on the pleasure of great calculating machines before he can get a new insight into the underlying philosophies of his subject, or must he acquire a mathematical equipment which would only enable him to play about on the fringe of quantum chemistry ?

Bohr's theory of atomic structure was in its mathematical dress difficult for the chemist, and it seemed impossible to base a mathematical theory of valence upon it. Yet G. N. Lewis, by introducing a beautiful and simple conceptual picture, provided the chemist with a framework into which he could fit—mosaic-like—the 'irreducible stubborn facts' of chemistry, thereby giving a new meaning to them.

The ineffectual behaviour of Hamlet was due to the fact that out of the disconnected fragments of experience he chose no pattern or framework ; and theoretical chemistry is in danger of becoming incoherent for lack of a guiding pattern. Again the time has come when chemists need a conception —based upon modern quantum mechanics—which will unify and co-ordinate chemical phenomena in the same way as did the conceptions of G. N. Lewis. Fortunately there are, in the hands of a few, guiding patterns and frameworks into which it is possible to set large sections of chemical phenomena and to see them with new meaning and new insight. The conceptions and methods of such frameworks are described and discussed by Prof. Hellmann in the monograph now under notice.

It is necessary that these methods of thought should not remain with the few active workers in this field ; they should rather be an integral part of the equipment of all chemists. It is not sufficient to graft these new conceptions on to old ideas as reservations and restrictions to be borne in mind while continuing to use older methods. We feel that this monograph is an excellent beginning in the presentation of such underlying principles of quantum chemistry.

The two main methods of approximation to the study of valence problems are presented in great detail. These two schemes—one, the homopolar or bond eigenfunction method associated with the names of Heitler, London, Slater and Pauling; the other, the method of molecular orbitals developed by Lennard-Jones, Hund and Mulliken—already provide a means of describing and explaining the valence behaviour of large groups of chemical substances. Nor are all the successes confined to the relatively simple chemical compounds—the theory of resonance in conjugated compounds has had great influence on the theories of the stability and reactivity of organic molecules.

Another field in which the appearance of quantum concepts has led to new understanding and fresh impetus is that of chemical reaction kinetics. In this book the basis of the work of Eyring and his school on one hand and of Polanyi on the other is very fully discussed. One chapter is devoted to the application of these conceptions to the semi-empirical calculation of activation energies and to the calculation of absolute reaction velocities.

"Einführung in die Quantenchemie" is filling a real need. For those who are able to use the mathematics of the approximate methods of quantum chemistry, this monograph with its very full bibliography is an admirable introduction. On the other hand, by collecting in one place and correlating the various methods which have been used in quantum chemistry, this book may enable readers to find a conceptual structure which will give rise to a new co-ordination of chemical phenomena in a form which can be understood and handled by non-mathematicians.

Mathematics for Technical Students

(1) Calculus

By Prof. Herman W. March and Prof. Henry C. Wolff. (Modern Mathematical Texts.) Pp. xvii + 424. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 15*s*.

(2) The Elementary Theory of Operational Mathematics

By Prof. Eugene Stephens. (Electrical Engineering Texts.) Pp. xi + 313. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 21*s*.

(1) "THE bond of union among the physical sciences is the mathematical spirit and the mathematical method which pervade them." Thus in their admirable text-book, Profs. March and Wolff endeavour to develop the fundamental principles of the calculus which play so important a part in the physical sciences, and to lay the emphasis upon the mode of thought so that even though the student may forget the details of the subject, he will continue to apply these fundamental modes of thinking in his later scientific or technical career.

While the needs of technical students have been foremost in the minds of the authors, the book is equally adapted to others. For, in the opinion of Profs. March and Wolff, mathematical courses for technical students and for the students of pure science do not materially differ. Both classes of students profit by the type of study that is assumed to be adapted to the other class.

The book is not divided into two separate parts devoted to the differential and integral calculus respectively. Integration with the determination of the constant of integration and the definite integral as the limit of a sum, are given immediately following the differentiation of algebraic functions, and before the differentiation of the transcendental functions. Thus many of the most important applications of the calculus occur early in the course and constantly recur. Further, by this arrangement the student is in a better position to pursue courses in physics and mechanics simultaneously with the calculus.

(2) In electrical engineering, the algebraic method as an aid to the simplification of work with the differential equations and integrals encountered in mathematical physics, has only been partially appreciated hitherto. The text of Prof. Stephens's book on the elementary theory of operational mathematics is an attempt both to search out the history of these methods and to codify the set of theorems found. Owing to the fundamental character of the methods used, the book will probably be of interest to the mathematician; but the author is careful to point out that it is written primarily for "all those who live and work to make mathematics useful to mankind, because of the beauty and simplicity of the operational forms and because of their wide application to the daily tasks of teachers and workers in engineering schools and industrial laboratories".

The essential nature of the method here presented consists of: (1) 'algebraizing' the operators of the differential and integral calculus; (2) simplifying the algebraic forms thus obtained; and (3) re-interpreting the resulting forms as operators which are then found to be easier to use than the original ones. Wherever the methods are not rigorously justified, reference is made to "The Theory of Linear Operators", by H. T. Davis: and a very extensive bibliography is provided.

Der Chemie-Ingenieur:

ein Handbuch der physikalischen Arbeitsmethoden in chemischen und verwandten Industriebetrieben. Herausgegeben von A. Eucken und M. Jakob. Band 3: Chemische Operationen. Teil 1: Physikalisch-chemische und wirtschaftliche Gesichtspunkte für die durchführung chemischer Operationen. Herausgegeben von A. Eucken. Pp. xvi+564. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1937.) 52 gold marks.

THIS book is the first part of volume 3 of a well-known work on chemical engineering under the editorship of Eucken and Jakob, the former of whom in the opening chapter of this book considers the determination of the maximum output from the point of view of chemical equilibrium, both of homogeneous and heterogeneous systems under constant conditions of temperature, as well as the thermodynamics involved and practical applications thereof.

The first part of the second chapter is from the pen of H. von Dohse, and is concerned with the subject of the velocity of reaction particularly in homogeneous systems and where catalysts are present. K. von Fischbeck, who is responsible for the second part of this chapter, has treated the subject of the reaction velocity in heterogeneous systems such as may arise in the burning of coal, decomposition of salts and between compact bodies.

Responsibility for the last section of this chapter is taken by G. von Danikohler, who has considered such subjects as the influence of diffusion, flow and heat on the yield in reactions carried out on an industrial scale.

Involving as they do the application of the principles of physical chemistry to industrial problems, the treatment of the aspects discussed in these chapters is quantitative as well as qualitative, and numerous references are made to much recent work.

Not of least interest and importance to the chemical engineer and industrialist is the cost of the various operations involved in the manufacture, packing and selling of his product, an important subject which is discussed in Chapter iii by L. von. Meyer, who, realizing the variations which may be introduced, has wisely stressed the general principles involved.

The book is uniform with the parts of volumes 1 and 2, and contains much useful and valuable information relating to the transfer of a process from the laboratory to the industrial scale, which should be of assistance to the chemical engineer and industrial chemist.

The Bantu-speaking Tribes of South Africa:

an Ethnographical Survey. Edited for the (South African) Inter-University Committee for African Studies by I. Schapera. Pp. xv+453+24 plates. (London: George Routledge and Sons, Ltd., 1937.) 21*s*. net.

IN view of the increasing importance of native policy as a factor in determining the future of British and Mandated Africa, it is essentially desirable that accurate information about the native should be available in a readily accessible and easily assimilable form. For this purpose this volume is in every way admirable. The life of the Bantu-speaking peoples of South Africa is described from every side as lived before modification by European contacts. Each chapter is written by an acknowledged expert among South African anthropologists. Among those dealing with the more general questions, Prof. Raymond Dart writes on racial origins and Dr. A. J. H. Godwin describes the geographical environment, while Dr. N. J. van Warmilo deals with grouping and racial history. Dr. C. M. Doke is responsible for the account of language and Mrs. Hoernlé analyses their social organization and records their magical and medical practices. The other aspects of native life and culture are covered by writers of equal authority; the editor himself has been responsible for economics, politics, and law and justice.

It is unnecessary to enter further into detail. The name of the editor is a sufficient guarantee that nothing which is essential to give the layman a comprehensive view of South Africa Bantu culture—using the term in a broad sense—has been omitted. The special merit of the book, however, is that not only does it deal with the native of South Africa as he was, but it also gives objectively, and impartially, be it said, an adequate account of present-day conditions—the native as he is, after contact with European civilization and now that he has become a 'problem'—information that is essential, if we in Great Britain are to understand what is involved in the difficulties which the people of the Union of South Africa have to solve. Here Prof. Schapera, Dr. Monica Hunter, and the colleagues who have collaborated with them are guides whose scientific detachment is above suspicion of political bias.

Light:

Principles and Experiments. By Prof. George S. Monk. Pp. xi + 477. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 30*s*.

THERE is a rapid increase in the number of elementary treatises on light intended to serve the needs of the student of a good pass or first year honours grade. Prof. Monk's book is of this standard. It provides a very well balanced course of geometrical and physical optics in which the emphasis is, naturally, on the physical side. The fundamentals of the subject are carefully developed and expounded, and, though the treatment is relatively elementary, intensity-distribution problems receive due consideration, and there are concise but comprehensive chapters on spectra, light and material media, the effects of magnetic and electric fields, and the eye and colour vision. The geometrical part contains a useful discussion of the cardinal points of an optical system developed on classical lines, apertures, aberrations, photometry and instruments. About seventy pages are devoted to a series of twenty-three laboratory experiments, ranging from the focal lengths of simple lenses to the optical constants of metals.

The book forms an excellent introduction to a more specialized treatment for students in an honours grade.

A. F.

Natural and Artificial Rubber: the Elasticity of Long-chain Molecules

By Prof. H. Mark, University of Vienna

INTRODUCTION

THE elasticity of rubber and related substances is not of the same kind as the elasticity of steel or glass, but seems more to possess the nature of the elasticity of gases. This may appear strange, because we are accustomed to regard rubber as a solid body, but as a matter of fact technical men have since long realized this peculiar relationship. Hence they nearly always use rubber or rubber-like material in conjunction with air, when they try to produce a high elastic combination as a ball, a tube, a tyre, etc., but they never combine soft rubber with metals or other solid bodies. Only hard rubber is used in this field. Our technical experience so far can be summarized thus: soft rubber is best used in conjunction with gases, hard rubber with solid bodies.

It may be very surprising that recent research work in the field of high molecular substances has shown, indeed, that the elasticity of soft rubber is based on exactly the same fundamental effect as the elasticity of gases, while on the other hand the elastic properties of hard rubber are closely related to those of metals or other solid bodies.

We have well-founded ideas on the elastic behaviour of normal crystals, and we know that the single atoms or ions oscillate around equilibrium positions, which are shifted when we extend the crystal elastically. The energy which enters in this way in the lattice represents the elastic energy of the sample; this is the cause of the experimentally observed fact that a normal crystal cools during rapid extension and heats during rapid relaxation. On the other hand, soft rubber heats during rapid extension and cools down when it is rapidly relaxed, while hard rubber shows the same behaviour as normal solid crystals.

All these facts show that we have to look for quite a different mechanism when we want to explain the high reversible elasticity of soft rubber and a number of analogous substances, which are grouped together under the title 'synthetic rubber', but may be built up from substances chemically quite different. Searching for such a new explanation, we have first to note that all bodies with characteristic rubber-like elasticity have one common property, namely, they are built up of long chain-like molecules, every one of which consists of some hundred members and every one of which shows a remarkable internal flexibility. Substances built up of long thread-like molecules, so-called main-valence chains, play an important part in the constitution of organized matter. There are rubber, proteins, cellulose, chitin, starch, etc. Synthetic products of the same molecular type are the well-known high polymeric substances such as polystyrene, buna, duprene, sowpren, thiokol, perdurene, etc. Always, when the long chains are flexible, as is the case with rubber, proteins, buna, duprene, thiokol, sulphur, etc., we get typical rubber-like elasticity, while in the case of more or less stiff chains—cellulose, chitin, polystyrene—we get plastic materials, which may be used technically as artificial resins.

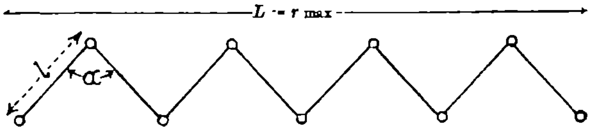
We have therefore to put the question: What particular properties have long flexible chain-like molecules?

BEHAVIOUR OF A SINGLE CHAIN-MOLECULE

Starting from very simple assumptions, we study an isolated chain-molecule of the type

$$\underbrace{CH_3.CH_2.CH_2 \quad . \quad . \quad . \quad . \quad . \quad CH_2.CH_2.CH_3}_{n \text{ C-atoms}},$$

n being a number between 100 and 10,000. We are quite aware that our results must be preliminary, because rubber does not consist of one single chain of this type, but contains many such chains substituted with methyl groups and linked together by secondary valences.



$n = 9$

Fig. 1.

Bragg's experiments show that the length of every carbon linkage is 1·45 A. and stereochemistry teaches us that the angle between two valencies is 109°, and that, around every linkage, free or nearly free rotation has to be assumed. When we stretch the molecule we get a chain of the length

$$L = (n - 1).\ l \sin \frac{\alpha}{2} = r_{\max}$$

the shape of which is shown in Fig. 1. The distance between the first and the last atom of the chain represents the maximum possible distance which can be produced between these two atoms, and can be realized only in the way represented by Fig. 1.

But when we prescribe for the distance between the first and last C-atom another value r such that

$$r < r_{\max},$$

it is easily seen that we can obtain this distance in many different ways. According to the flexibility of the chain, we are free to fold it together in different ways, so that the distance between the ends is just r. To every given r belongs a certain number of possibilities, realizing this value in geometrically different ways. This reminds us rather closely of the Boltzmann statistics of an ideal gas, where we also have to enumerate the possibilities of microscopic realization for one given macroscopic state. In our case the macroscopic state is the fixed distance r between the chain-ends, and the different possibilities or aspects are afforded by the different shapes of the chain, all of which give the same distance between the ends (compare Fig. 2).

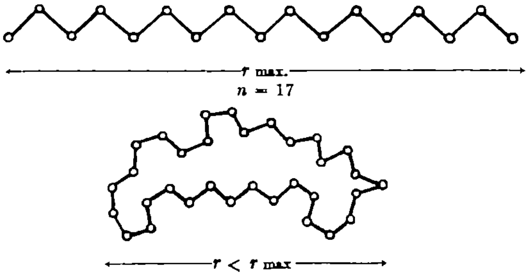


Fig. 2.

These considerations invite us to assume that a chain-like molecule, being in thermodynamical equilibrium with its surrounding—getting from all directions at random thermal impulses—will by itself always appear in that state which has the greatest number of aspects. This means nothing else but the application of Boltzmann's ideas to the case of a single chain-like molecule. When we have the extended chain and allow it to be in free contact with its surroundings, it will try to increase its number of possible states, that is, to reach a higher statistical probability. This is certainly not the extended state, because that has the realization number *one*. It will be another state, in which the ends of the chain are nearer together than in the case shown in Fig. 1. That means nothing else but that the extended chain will *contract by itself*, as an ideal gas expands by itself, because the number of aspects increases with increasing volume of the gas. On the other hand, when we want to extend the contracted chain, we have to bring it in a less probable state. According to the general laws of thermodynamics, this is only possible if one puts work into the system, and this work is used to extend the elastic chain.

It is seen, therefore, that the contraction of an extended piece of rubber is not due to the action of molecular forces but to the thermal movement of the single members in the different chain molecules which build up the sample. Exactly in the same way, the pressure which an ideal gas exerts on its wall is not due to forces but to the thermal movement of the single molecules. It is very significant that in both cases thermodynamics requires that with increasing temperature the effect should increase. In fact, it has long been well known that the pressure of an ideal gas is proportional to the absolute temperature, and it was a very important observation made independently by K. H. Meyer, to whom we owe the new development on this field, and L. S. Ornstein that the elasticity of rubber also increases with the temperature.

It is not very difficult to put all this in formulæ, which was done by E Guth some years ago. To every prescribed distance r between the ends of the chain belongs a certain number of realization possibilities. It can be calculated by the laws of probability. One finds the probability, W, that a chain with n members each of the length l, combined together by a valence angle α, should give a distance r between its first and last atom is given by:

$$W(n, l, a, r)r^2dr = \sqrt{\frac{6}{\pi}} \cdot \frac{3}{n^{3/2}\, l_\alpha^2} \cdot \exp\left(-\frac{3r^2}{2nl_\alpha^2}\right) r^2dr.$$

$$l_\alpha^2 = l^2 \frac{1 + \cos\alpha}{1 - \cos\alpha} \qquad (1)$$

When we regard this as the statistical probability function of our system, we may define the *entropy of a single chain* by the well-known Boltzmann expression,

$$S = k \log W, \qquad (2)$$

and can derive from the entropy all properties of the substance. It is well known that in the theory of ideal gases the pressure can be calculated from the entropy by the formula

$$p = +\left(\frac{\partial S}{\partial V}\right)_T . T.$$

When we put in this equation the entropy of an ideal gas, we get the fundamental equation of state

$$pV = RT.$$

In very close analogy to this we can put for our chain molecule the relation

$$\sigma = -\left(\frac{\partial S}{\partial \delta l}\right)_T . T$$

σ = tension or stress. (3)
δl = extension.

Taking (2) for S and (1) for W, we get the equation of state for our system. In this way we obtain:

$$\sigma = kT\frac{3}{nl^2} \cdot \frac{1 - \cos\alpha}{1 + \cos\alpha} \cdot \delta l, \qquad (4)$$

which is nothing else than a theoretical expression for the *extension curve* of a single flexible molecular chain in thermodynamical equilibrium with its surroundings.

APPLICATION OF THE THEORY

It is interesting to note that experiment is in very fair agreement with these ideas. We have already mentioned the experiments of K. H. Meyer and L. S. Ornstein, which show the fundamental fact that the elasticity of rubber increases with increasing temperature. Other measurements due to L. Hock and to P. A. Thiessen show that the thermo-elastic properties of rubber do not at all contradict the ideas of statistical elasticity. The relation (4) contains the number n of the chain-members, which is closely connected with its molecular weight. In fact, W. Kuhn, to whom we owe very interesting calculations on this field, was able to derive the average molecular weight of rubber starting from its modulus of elasticity. He got values between 20,000 and 100,000, in very satisfactory agreement with other methods earlier applied. Another consequence is that the specific heat of stretched rubber measured at constant length must be different from the specific heat measured at constant tension. This also has been proved experimentally, and supports the ideas put forward in this article.

To get real quantitative agreement between experiment and theory it is necessary to improve our model in two directions:

(1) We have to consider that a macroscopic piece of rubber consists of *many* long-chain molecules connected together by van der Waals' forces. This means that the molecules are not independent of one another, but have the property of hindering each other during the extension.

(2) It is not necessary that the rotation around the single carbon linkages in one chain should be really free. There can be some steric hindrance, which allows only a certain amount of free rotation.

Both improvements are on the same lines by which one proceeds from the equation of state of an ideal gas to the van der Waals' equation.

Our second point is identical with the van der Waals' volume correction, while the first one brings into consideration the forces between the different molecules. From the theory of gases we know that at high pressures and low temperatures during the compression of a gas a new phase, namely a liquid phase, arises, and that in this region an equilibrium between two phases plays an important part in the behaviour of the system. In very close analogy it has been found that rubber also shows at high tensions and low temperatures a new phase, namely, the small rubber crystals, which were detected by J. R. Katz and afterwards were investigated by many other workers. Under these conditions, again, an equilibrium between liquid and solid rubber determines the behaviour of the system. This equilibrium was carefully investigated by G. v. Susich and by P. A. Thiessen and his collaborators. In gases the condensation process is subject to the Clausius-Clapeyron equation, and it is very easy to derive from the formulæ mentioned above a relation which corresponds exactly to the Clausius-Clapeyron equation and which seems to be in very good agreement with the experimental facts found by L. Hock, G. v. Susich, P. A. Thiessen and others.

There is no question that a lot of experimental and theoretical work has still to be done before we shall be able to survey the whole field of elastic extensibility of high-molecular substances, but we seem to be on the right path, and many other properties, such as the viscosity of high-molecular solutions and the dielectric behaviour of long-chain dipoles, will be elucidated by such studies.

Science, Logic and Philosophy*

By Dr. Harold Jeffreys, F.R.S.

MUCH in current discussion of scientific method turns on the ancient problem of idealism versus realism. As I understand it, an idealist holds that he is inventing a universe for himself as he goes along, while a realist holds that there is a "universe existing independently of our thought and our examination of it"—to use the words of Prof. Dingle—and that what we are doing in science is to find out something about this universe. Realism has been severely criticized, and some forms of it not too severely. Nevertheless, I do not believe that anybody is an idealist. If an idealist regards the world as a mere mental construct of his own, so are other people, being part of that world. Hence if an idealist argues with other people he must think that he is arguing with his own mental constructs, and all discussion should be futile for him. So far as my observation goes, people that call themselves idealists are at least as argumentative as the rest of mankind; whereas if their belief was genuine I should have expected them to retire into a state of psychotic isolation.

---

*Based on a lecture given at the University of Leeds on January 31.

The great difficulty about idealism is that every idealist must have his own separate idealism. If A and B are idealists, A thinks that he has invented B and vice versa. The relation between them is that between 'Alice' and the 'Red King'; but while Alice was willing to believe that she was imagining the King, she found the idea that the King was imagining her quite intolerable. This fundamental asymmetry makes it quite impossible for two idealists to agree. They may support idealism in similar forms of words, but each is advocating his own particular idealism, which is flatly contradictory to the other's; and if they think that they agree they must have used some other principle.

Nevertheless, idealism contains an important principle recognized by Karl Pearson[1], that any person's data consist of his own individual experiences and that his opinions are the result of his own individual thought acting on those experiences. Any form of realism that denies this is merely false in fact. A hypothesis does not exist until some one person has thought of it; an inference does not exist until one person has made it. We must and do in fact begin with the individual. But early in life he recognizes groups of sensations that habitually occur together, and in particular he notices resemblances between those groups that we, as adults, call observations of oneself and other people. When he learns to speak he has already made the observation that sounds belonging to these groups are habitually associated with other groups, and has inferred the rule that we should express by saying that particular things and actions are denoted by particular words; and when he himself uses language he has generalized the rule to say that it may be expected to hold for future events.

The use of language accepts the principle that generalization from experience is possible; and this is far from being the only such generalization made in infancy. But if we accept it in one case we have no ground for denying it in another. But he also observes similarities of appearance and behaviour between himself and other people, and as he is associated with a conscious personality it is a natural generalization to suppose that other people are too. Thus the departure from primitive solipsism is made possible by admitting the possibility of generalization. Further, it abolishes the asymmetry between different people, and it is possible for them to understand and agree with each other simultaneously, which appears to be quite impossible for two idealists. But it does not say that nothing is to be believed until everybody believes it. The situation is that one person makes an observation or an inference; but this is an individual act. If he reports it to anybody else the second person must himself make an individual act of acceptance or rejection; all that the first can say is that, from the observed similarities between himself and other people, he would expect the second to accept it. The facts that organized society is possible and that scientific disagreements tend to disappear when the participants exchange their data or when new data accumulate are confirmation of this generalization; but to take universal agreement as a primary requisite for belief is a superfluous hypothesis, and it cannot be applied in practice. It is impossible for a person to ask everybody's permission before he believes anything.

The need for an understanding of generalization is quite fundamental. It is not worth while to invent or postulate an object unless we find that we can co-ordinate many sensations by doing so. The Nautical Almanac's predictions of planetary positions, an engineer's estimate of the output of a new dynamo, and an agricultural statistician's advice to a farmer about the utility of a new fertilizer are all generalizations from experience. So are my expectations about the flavour of my next meal. Now if our reasoning is restricted to traditional logic such inferences are impossible. Traditional logic admits only three alternatives about any proposition: complete certainty, absolute denial, or blank ignorance. In pure mathematics it deals only with logical relations between nothing in particular, and is frankly admitted to have nothing to do with sensory experience until some extra hypotheses are supplied. In applied mathematics these are supplied, usually without mention of their origin, and results are deduced as exact consequences. Thus it is impossible to say anything at all until we can say it with certainty.

Generalizations from experience are not, however, made with certainty. To say that they are involves the fallacy known in logic as the excluded middle term. It appears in accounts of scientific method in various forms. Thus it may be said that a quantitative law is a description of the observations; but that refers only to the observations that have yet been made, and an infinite number of laws would fit any finite number of observations ([3], pp. 37–39). To infer any new observation from it we must select a particular law from this infinite set; and without some rule not contemplated in traditional logic there is no means of making such a selection, or therefore of preferring any prediction to any other. Conversely, if we say that we learn our laws from experience we can avoid the fallacy of the excluded middle only at the cost of admitting that there are valid inferences that are not made with certainty. We must, in fact, choose between three alternatives.

(1) Prediction is meaningless: then all practical men are wasting their time, the sun may rise in the west to-morrow, and human relations that depend on people understanding one another's language are impossible.

(2) Prediction is made deductively, not from experience, but from some general principle alleged to be logically certain; if experience plays any part at all it is only to fill in a few details. This is the attitude of many modern theoretical physicists. However, their general principles and their results differ even within the very limited field of knowledge where they have been applied; and at the most we can regard them only as guesses worthy of proper test by experiment.

(3) Generalizations from experience can be valid inferences, but are not made with certainty. But in that case traditional deductive logic is admitted to be inapplicable to either ordinary life or scientific method.

There are no other alternatives; nobody believes the first; the second is very doubtfully applicable at all, and has not been applied to the fundamental problems; the third is generally accepted, but asserts the inadequacy of deductive logic. It demands the notion of a degree of reasonable confidence, of which certainty and impossibility are the extreme possible values; but the former, while it may be approached by a generalization or an inference from one, is never quite attained.

The need is indeed obvious without this discussion if we consider the kind of inferences that we actually draw. Suppose that we measure the distance between two points once and get 18·1 mm.; we measure it again ten times and get values from 18·0 mm. to 18·2 mm.; we measure another distance ten times and get values from 17 mm. to 19 mm. What will we infer about the distance that we should get in a further measurement? Obviously we cannot infer a single exact value in any case; but we can say that in the second case the next value is very likely to lie between 18·0 mm. and 18·2 mm.; in the third it is much less likely; in the first we have no idea at all except that the most likely result will be 18·1 mm., unless we have independent evidence about the accuracy of our readings; if we have not, the next observation may depart by any amount. Everybody that has ever made observations is fully aware of these facts. Very few, however, have grasped the consequence, that any theory of inference that can make only exact predictions or none at all is for that reason inadequate. We must have a theory that deals with the probability of variations of different amounts. Meanwhile I shall use the adjectives "naive" to denote any theory, whether realist or idealist, that maintains that inferences are made with certainty, and "critical" for one that admits that they are not, but nevertheless have validity.

Again, suppose that we repeat the second and third of the above series of measures a day later, and get in each case an average value of 17·5 mm. Are we to say that this is a variation similar to what we have already found, or that the distance has changed? Evidently in the third series it is more likely to be of the old type than in the second; but where are we to draw the line? In neither case can we assign any definite value and say that any discrepancy less than this is certainly of the kind that we have already had and that any larger one certainly represents a change of distance. Yet we must draw some sort of a line somewhere, even though we cannot be sure of drawing it in the right place. Such problems are of everyday occurrence; but traditional logic has nothing whatever to say about them. That does not say that they cannot be treated mathematically; it is perfectly possible to generalize mathematics to give it greater elasticity, and modern physicists have done much in that direction. They have, however, shown a curious reluctance to recognize the inadequacy of traditional logic itself, being apparently saturated with the naive realistic ideas of applied mathematical teaching. Yet traditional logic denies the possibility of learning from experience, and it is right if we restrict this to mean learning with certainty; if we believe that we can learn from experience it must be with different degrees of probability.

The notion of probability as a statement of a degree of reasonable confidence goes back at least to James Bernoulli, and is quite explicit in the works of Bayes, Laplace, and a number of other writers. Other definitions have been attempted, but they all lead either to the introduction of superfluous postulates or are insufficiently general to cover the ground. I mention only one. Some writers speak of 'mathematical probability' as meaning simply that if there are n possible results of a trial and m of them include the event considered, the probability of the event is m/n. (See, for example, the series of reviews in NATURE of January 8, p. 55.) In earlier works, such as those of Laplace, this was stated with the proviso 'provided that all the ways are equally likely'. Thus it was not a definition of probability, since the notion occurred in the statement; it was a rule stating how to estimate probabilities in certain circumstances, the idea of probability itself being taken as already understood. If the proviso is dropped, however, we find that the 'mathematical probability' of a coin coming down heads is ½ even if it has been loaded with lead on one side and has already given ten heads in succession. The definition is simply a concession to traditional logic and discards the essence of the matter; and traditional logic admits no compromise. It says that the result of a trial, or of any number of trials, is simply unknown and there is no more to be said.

The question is, then, can we construct a mathematical theory of probability, in the ordinary sense of the term, that will be consistent, and will meet the requirements of scientific procedure—and incidentally of ordinary life? It turns out that we can. The fundamental idea is simply that of the probability of a proposition, given the data; we need the postulate that such probabilities can be arranged in an order*, and a few minor postulates and conventions that make it possible to assign numbers in a one-one correspondence to probabilities[2,3]. The principle of inverse probability follows as a theorem, and enables us to compare the probabilities of different hypotheses on the same data. The results are consistent in the sense that if we compare the probabilities of two hypotheses at any stage of our knowledge, and other information is afterwards attained, the ratio of the final probabilities will be the same in whatever order the new pieces of information are taken into account. (It is known that complete consistency cannot be proved even for pure mathematics.) Inconsistency can arise if we speak of the probability of a proposition without reference to the data, which is still liable to be done on account of an inadequate notation that does not mention the data explicitly; but with a correct notation (due in principle to W. E. Johnson) no such trouble can arise. The essential point is that to say that we can learn by experience is the same as saying that the probability of a proposition is a function of both the proposition and the data. With this theory we can proceed to discuss what confidence we may attach to hypotheses, given observed data, if we are to follow consistent rules, and not to have different standards of validity depending, say, on whose hypothesis we are discussing.

Ordinary and scientific reasoning both admit learning from experience and therefore recognize the inadequacy of deductive logic; and everybody admits the significance of the statement "on data r, p is more probable than q". Different people may disagree in particular cases about which is the more probable, but they agree that the statement has a meaning. We start with the agreement and postpone consideration of the differences. It turns out that they can be attributed either to incomplete working out of the results (which can happen in pure mathematics) or to allowing our beliefs to be influenced by our wishes. Science has got on fairly well without any formal statement of its principles, but it is definitely advantageous in practice to have such a statement, which will at least allow these complications to be placed where we can see them and may possibly enable them to be removed, since they are perfectly capable of being tested; and on the theoretical side it liberates inference from experience from the charge of being indistinguishable from a set of arbitrary assumptions. It turns out that the apparent assumptions are all closely connected and that the process is much more coherent than might have been thought.

One immediate result is that the traditional idea of causality must be discarded as possibly wrong and certainly useless. With the possible exception of mere counting, a scientific law is never exactly verified. This fact appears to be quite unknown to philosophical critics and to be conveniently forgotten by most scientists when talking about the basis of science. We must either choose our laws to fit the data exactly or be satisfied with a compromise. At the times when Euclid and Newton worked, the unexplained discrepancies were some hundreds of times those that ultimately led to modifications of their laws; but in spite of this the laws were taught as having deductive certainty. Scientific success does not consist in exact correspondence, but in the improvement of approximation. However carefully we measure, our measures never repeat themselves exactly; we may speak of 'experimental error' in some metaphysical sense, but the solid fact is that the measures vary—unless we use so coarse a measuring scale that all variations are swamped by the step of the scale, and if we do that even such a law as the additive property of distance is not verified. Even the simple law that the length of a solid body is constant is not exactly verified. But what is true is that the variation is irregular, and we can consider the hypothesis of 'random variation'; that is, that there is a part of each measure which cannot be foretold at all from previous measures.

On this hypothesis we can find a distribution of the probability of the remaining or permanent part. But this hypothesis is not certain, and we are entitled to consider the alternative that only part of the variation is random, the rest varying at an unknown rate the most probable value of which has to be estimated from the observations. It might account for any fraction of the total variation*, and the prior probability of its possible values has to be distributed uniformly within the range permitted by the total variation to express this. We can then compare the total probabilities, given the observations, that the whole of the variation is random and that part of it is systematic in this sense. It is found that if the new term as found by a least squares solution is more than a certain amount, the observations increase the probability that part of the variation is systematic; if it is less than this amount, they decrease it and support the proposition that the whole of the variation is random. The critical value is usually two to three times the standard error as usually estimated, and therefore is in good agreement with the rule that has been found to work well in practice.

---

* The postulate is actually that "on data r, p is more probable than q" has a meaning and that this relation is transitive; when a practical statistician gives advice on the "best" way to proceed in order to achieve a desired result, he is assuming that "p is more probable on data q than on data r" has a meaning. But the latter can be proved from the other postulates and need not be taken as a separate postulate.

The method can be stated as saying that, if we have no previous knowledge beyond the fact that the new parameter is worth considering, we take the prior probability that it is zero as ½, and we accept it as genuine if the posterior probability is less than ½ (though not with much confidence unless it is considerably less). This is what I have called a 'simplicity postulate' ([2], p. 250). Some objection has been made to it by alleged naive realists, who would apparently accept every estimate uncritically as an exact determination. I can only say that every competent statistician does reject new parameters below about the limit that I find, and that nobody who has ever accepted two estimates as consistent because they agreed within the standard error of their difference is a naive realist. Anybody who rejects the simplicity postulate must apparently believe that the Nautical Almanac Office, in predicting the positions of the planets, would get better agreement with future observation by fitting polynomials exactly to the whole of the observations and then extrapolating, than it gets by the actual method of finding the minimum number of parameters by least squares and calculating according to the law of gravitation. But if anybody really believes that, he would add to the clarity of discussion by saying so explicitly. If, on the other hand, current procedure is admitted as valid, it is thereby admitted that probability must be introduced at some stage before we can get practical results. But if it has to come in sooner or later anyhow, we may as well have it at the start; and then it is found to solve most of the problems that have led to controversy, since the apparent postulates turn out to be either superfluous or legitimate inferences from experience.

---

* It is because it often accounts for nearly all of it that a physicist can think that there is evidence for strict causality. In such a subject as agriculture no such confusion is possible. Fisher's term "the analysis of variance", though used by him only in relation to a particular technique, goes straight to the root of the general problem.

Obituary Notices

Mr. W. H. B. Cameron

The untimely death of Mr. W. H. B. Cameron on February 16, at the early age of thirty-six years, came as a great shock to all who knew him.

A native of Ulster, Mr. Cameron entered Queen's University, Belfast, as Sullivan scholar from the Royal Belfast Academical Institution, and graduated in 1923 with honours in physics and mathematical physics. During the next three years he was successively Musgrave demonstrator in physics and Musgrave research student at that University, and undertook research work in spectroscopy under the direction of Dr. R. C. Johnson. His work on spectra associated with oxygen and nitrogen, for which he was awarded the M.Sc. degree, was followed by work on the nitrogen afterglow, and on the production of various spectra in the presence of neon and argon. During this work he discovered the bands of carbon monoxide now generally known as the Cameron bands, and also some new bands of silicon oxide.

Mr. Cameron joined the staff of the Physics Department at the University of Sheffield in 1926, and continued there his spectroscopic researches, working first on the band spectrum of sulphur, and later carrying out the construction of a novel grating spectrograph. Later work was done in collaboration with his colleague, Dr. A. Elliott, on intensity measurements of the first positive band spectrum of nitrogen excited by various methods. This was followed by a joint analysis of the visible emission bands of chlorine, recently published, in which it was shown that the bands are emitted by singly ionized chlorine molecules. Further work on the continuous spectra excited in chlorine by active nitrogen was in progress when he was stricken by his fatal illness.

Mr. Cameron's activities, however, were by no means confined to his scientific work. He had been leader of the University Rover Crew from its inception, as well as resident tutor at Crewe Hall and supervisor of University lodgings since 1936. During his time in Sheffield he was actively associated with St. Andrew's Presbyterian Church. He was secretary and past president of the Sheffield Physical Society, and an associate of the Institute of Physics.

In all phases of his varied activities, Mr. Cameron's work was characterized by unflagging patience and carefulness. This was particularly evident in his dealings with students, who held him in high affection and for whom no amount of work was a trouble to him. Besides being an excellent and sympathetic teacher and a delightful colleague, he had many sterling qualities; his modest manner, quiet humour, and kindly smile endeared him to all with whom he associated. It can truly be said of him that he spent himself gladly in the service of others. R. W. L.

Sir Arthur Downes

SIR ARTHUR DOWNES, who died on March 11, at his home on Mount Carmel, Haifa, Palestine, at the age of eighty-six years, had a long career in the public health service. He was educated at Shrewsbury School, University College, London, and the University of Aberdeen, where he graduated M.B., C.M. with honours in 1873. He became M.D. in 1875, and took the diploma of public health, Cambridge, in 1877.

After serving as deputy medical officer for Shropshire, and medical officer of health for the Essex Combined Areas, 1879–99, Downes was made inspector in the old Local Government Board, rising to become its senior medical inspector. He represented that body on many occasions, and served on the Royal Commission on the Poor Laws, and on a number of departmental committees.

Sir Arthur Downes will be best remembered for the pioneer work he did on the effect of light in inducing certain chemical changes, upon protoplasm and micro-organisms, and upon the activity of enzymes, publishing several communications on these subjects between 1877 and 1886, alone or in association with T. P. Blunt, in the *Chemical News*, *Proceedings of the Royal Society* and NATURE. Downes and Blunt showed that oxalic acid is completely oxidized and hydrogen peroxide is partially destroyed by insolation. In their "Researches on the Effect of Light upon Bacteria and other Organisms" in 1877, they found that light is inimical to the development of bacteria and micro-fungi, and under favourable conditions may wholly prevent development, the fitness of the culture liquid for growth being unimpaired, and they stated that this effect appeared to be associated with the actinic rays.

They carried this investigation a stage further in 1878 in their work "On the Influence of Light on Protoplasm". They tested the action of light upon Bacteria and Torulæ grown in test-tubes screened with different coloured glasses, the light-transmission of which was determined spectroscopically, and found that the action depends chiefly upon the blue and violet rays. Downes published another paper in 1886 on "The Action of Sunlight on Micro-Organisms", and in a letter in NATURE of the same year (34, 546) stated that the enzymes invertase, malt diastase, pancreatic diastase and trypsin, are all destroyed by insolation for a month.

Not inappropriately, Downes became a vice-president of the Sunlight League; he was knighted in 1910, and held the Order of the Crown of Belgium.

R. T. HEWLETT.

Sir Raymond Crawfurd

WE regret to announce the death on March 9 at the age of seventy-two years of Sir Raymond Crawfurd, registrar of the Royal College of Physicians of London, consulting physician to King's College Hospital and fellow of King's College, London.

Raymond Henry Payne Crawfurd was born on November 9, 1865, at East Grinstead, where he afterwards became consulting physician to the dispensary. He was the son of the Rev. Walter Payne Crawfurd, and was educated at Winchester and New College, Oxford. He qualified M.B. in 1894 and M.D. in 1896 with a thesis on Graves's disease, on which he afterwards contributed an article to Quain's "Dictionary of Medicine" (1900). In addition to his position on the staff of King's College Hospital, to which he was appointed assistant physician in 1898, dean in 1900 and full physician in 1905, his two chief spheres of activity were Epsom College, where he was chairman of the Council for thirteen years, and the Royal College of Physicians, where he was successively Fitzpatrick lecturer (1911–12), examiner (1912–16), censor (1918), Harveian orator (1919) and registrar from 1925 until the time of his death.

Apart from his joint editorship with Dr. (now Sir Farquhar) Buzzard of the fourth edition of Burney Yeo's "Manual of Treatment" (1909), Crawfurd contributed little to the literature of modern medicine, but he took a scholarly interest in the history of his art, being secretary of the section of medical history in the International Congress of Medicine held in London in 1913 and afterwards president of the Section of the History of Medicine of the Royal Society of Medicine, in the formation of which he took an active part. In 1909 he published a work entitled "The Last Days of Charles II", and in 1911 and 1912 chose as the subjects of his Fitzpatrick lectures "The King's Evil" and "Echoes of Pestilence in Literature and Art" respectively. Crawfurd was not only a fine scholar and an urbane and kindly physician, but also an excellent organizer and man of business whose loss it will be difficult to replace.

J. D. R.

WE regret to announce the following deaths:

Mr. Frederick J. Gould, author of many papers on moral education and world unity, who devoted his life to the promotion of social progress, on April 6, aged eighty-two years.

Prof. F. Mesnil, of the Pasteur Institute of Paris, member of the Section of Anatomy and Zoology of the Paris Academy of Sciences, aged seventy years.

Prof. Otto Naegeli, professor of internal medicine and director of the Medical Clinic in Zurich, known for his work on diseases of the blood, aged sixty-seven years.

Prof. D. W. Hering, emeritus professor of physics in New York University, on March 24, aged eighty-eight years.

Mr. F. A. Molitor, consulting engineer of New York, known for his work in railroad engineering, on March 12, aged sixty-nine years.

News and Views

Science at the Empire Exhibition, Glasgow

THE Empire Exhibition, which opens next month at Glasgow, will be the largest and most representative exhibition, with the exception of Wembley, that has been held in the history of the British Commonwealth. The Exhibition will present an impressive representation of the industrial and manufacturing capacity of the Empire and will show the progress of civilization within the Empire in many of its different aspects. Both in the industrial exhibits and in those for which the Government is directly responsible, research will occupy a prominent position. The theme of research will be symbolized in the huge sculptured feature, more than 40 ft. in height, which occupies the lofty entrance court of the United Kingdom Pavilion. Above the 'original elements', earth, water and air, represented by a golden sphere about which water continuously plays, a figure typifying man's questing spirit is seen to ride on a great silver wave. This figure bears the symbols of energy which science has placed within the grasp of man. The first of the four exhibition halls, each covering an area of 5,000 square feet, which form the United Kingdom Pavilion, is being devoted to a 'Fitter Britain' exhibit organized by the Ministry of Health in co-operation with the Board of Education, the Scottish Department of Health and the National Fitness Council. This exhibit will illustrate in a striking and interesting manner how the application of scientific knowledge is leading to a healthier nation.

EXHIBITS in the other three halls in the Pavilion have been organized by the Department of Scientific and Industrial Research. The aim of these halls is to demonstrate the part played by scientific knowledge and research in the industrial life of the nation. The three great national industries, coal, iron and steel, and shipbuilding, have been selected to illustrate this theme, and one hall is devoted to each of these subjects. In planning the exhibits the Department has had the fullest co-operation from industry. Important industrial organizations, such as the Mining Association of Great Britain, the Gas Federation, the Iron and Steel Federation and the Shipbuilding Conference, besides scores of leading firms, have freely given their assistance. Elsewhere in the Exhibition, the Ministry of Agriculture and Fisheries and the Forestry Commission, in co-operation with the Scottish Department of Agriculture and the Scottish Fishery Board, are showing exhibits illustrating some of the benefits which modern research has brought to agriculture, fishing and forestry. In the agricultural section, dairying, animal nutrition, fruit growing, land crop improvement and animal diseases are dealt with. One interesting section will deal with the gas storage of fruit developed by the Food Investigation Board, and another shows the application of chemistry to the problem of keeping soil fertile. In the forestry section the Forest Products Research Laboratory is co-operating with the Forestry Commission in staging an exhibit illustrating the work of the Laboratory as applied to home-grown timber. Another application of industrial research will be shown in an exhibit in the Palace of Engineering arranged by the Home Office, which will demonstrate modern methods of promoting the safety, health and welfare of industrial workers.

Press and the Public

THE broadsheet on "The Press and the Public" which has recently been issued by P E P (Political and Economic Planning) is of special interest in view of the recent attacks made upon the freedom of the Press in Great Britain by certain foreign powers, and of the Prime Minister's spirited championship of the Press in his speech at the annual dinner of the Parliamentary Press Gallery. The present broadsheet is concerned with the social influences of the Press, and its admirable exposition of the intricacy of the relationship with the public, and of the functions, amounting essentially to the provision of a daily magazine, which a newspaper is expected by many of its readers to fulfil, shows clearly how unfair is much of the criticism of the Press for sensationalism and inaccuracy. In its presentation and selection of material the Press is largely limited by the educational standards of its readers, and the broadsheet suggests that for one important class of readers all four of the popular dailies represent an improvement in taste and information. Equally it is emphasized that large numbers of readers would apparently support a newspaper considerably more sensational, more scandalous and more irresponsible than anything which the scruples of journalists, advertisers and proprietors and the restraints of the law will allow to appear.

THE basic function of the Press is to provide its readers with trustworthy news on which they can, if necessary, form sound opinions on current events, and in referring to the question of the standard of accuracy outside of the political field, the broadsheet points out that criticisms of accuracy in regard to scientific matters are criticisms not only of the Press but also of organized science itself. In scientific matters the giving of extra time to working up the statement properly would often prevent false or misleading impressions being conveyed. Though many scientific workers will have experience of inaccuracies even when a very careful statement was supplied to the Press, it should not be forgotten that organized science has as yet evolved no adequate means in Great Britain of telling the Press in advance what scientific workers have to say when the time comes for announcements of progress to be made. The broadsheet suggests that the influence of the Press may best be estimated by considering it as the principal agenda-making body for the everyday conversation of the ordinary man or woman, and therefore for that elusive element called public opinion. From that point of view alone, the broadsheet deserves the attention of those scientific workers who are interested in the shaping of public opinion and the encouragement of a scientific outlook or approach to the many social problems in which scientific and technical factors are involved.

The Conception of Curved Space

In a paper read at a meeting of the Victoria Institute, London, on April 4, entitled "Fallacies underlying the Einstein-Eddington Conception of Curved Space", Mr. Albert Eagle declared that "the whole conception does such violence to the nature of our minds that we can only call it a lie. . . ." He admitted that a disk might change its dimensions in a gravitational field, and so be distorted, but this should be regarded as a distortion of matter, not of space. The relativity formula for the distance between two points in a gravitational field might be correct if applied to the measurements taken with a material measuring rod, but such measurements should not be taken as the space of external reality. Mr. Eagle regarded the idea of curved space as self-contradictory, chiefly on psychological grounds. Moreover, he deprecated the attempt to abstract from reality everything that is tangible, and the attempt to reduce the physical universe to a purely geometrical universe. He complained that "practically no editor will publish an article making an attack on the theory". Quite apart from the difficulty under which most editors labour of finding space for the many contributions submitted, it may be suggested that a partial explanation may be, in Mr. Eagle's own words, that "Some people may think that I have more moral indignation, perhaps amounting even to animosity, against the theory of curved space than can be justified against any mere theory, no matter how erroneous or misleading it is."

Discovery

With the April issue our contemporary, *Discovery*, enters upon a new phase of its existence. It appears in new format, an octavo size, approximately that of a popular magazine, instead of a quarto ; and it is now published by the Cambridge University Press. *Discovery*, since its foundation soon after the Great War, with Sir J. J. Thom on, Sir Frederic Kenyon and the late Prof. R. S. Conway as its trustees, has consistently maintained a high standard of accuracy and a uniform distinction in style in bringing before an educated, but non-technical, public, information relating to the latest advances in knowledge and scientific discovery. Originally published by the house of John Murray, it was transferred to Messrs. Benn Bros. in 1924, by whom it has been published since that date until March of the current year, when responsibility for its future production was accepted by the Syndics of the Cambridge University Press. Dr. C. P. Snow, of Christ's College, Cambridge, will act as editor. Although the form of publication is changed, there will be no break in policy, which under the general supervision of the Committee representing the Trustees will be to continue to place before its readers, so far as possible, an accurate and universal view of advance, not only in physics, astronomy, biochemistry and medicine, but also in archæology, travel, architecture and the like in terms and phrasing of general appeal. The first issue in the new form holds out every hope of the fullest attainment of this aim. Among the contributors are Sir James Jeans, who writes on "The Origin of the Planets", and Dr. L. Infeld, a pupil of and collaborator with Prof. Einstein, on "Holes in Empty Space", while Mr. R. Philmore and Dr. J. Judkin contribute an amusing inquest on the scientific aspects of methods of murder in detective fiction. An article on new developments in colour photography is illustrated by a colour plate taken on the New Agfacolour film. We wish the new editor and publishers every success in their endeavour to enlarge popular interest in the progress of science.

Social Background of the Rise of Science

The sixth lecture of the series "Science in the Social World" organized by the Left Book Club Scientists' Group was delivered on March 28 by Prof. P. M. S. Blackett, his subject being "The Social Background of the Rise of Science in the Seventeenth Century". Prof. Blackett contrasted the view that the rather sudden rise of modern science in the seventeenth century was largely a matter of chance, with the view that this rise was closely related to the technical needs of the time. In particular, the progress of navigation and mining in the fifteenth and sixteenth centuries had led to a very urgent demand for the solution of certain scientific problems. The importance attached to these problems is shown by the efforts made to solve them. For example, at the end of the fifteenth century, eighty-three astronomers were employed in Lisbon on problems connected mainly with navigation, and by the end of the sixteenth century large financial rewards in the shape of prizes were offered for the solution of the problem of longitude. Again, Agricola in his book "De Re Metallica", published in 1556, listed sixteen different ways of pumping mines clear of water, a clear sign that no one of them was really satisfactory. It is interesting to note that the use of a clock at sea as a way of finding longitude was suggested so early as 1530, but that it was not until 1764 that this method was successfully used. Many of the scientific problems solved by Newton and his contemporaries had been raised into prominence between one and two hundred years before by the demand of practical techniques. The technical progress in the Middle Ages was not only an important contributory cause of the rise of modern science, but also led to a political struggle between the monarchy and feudal aristocracy against the rising merchant and business class. In England the struggle had been won by the latter by the time of the founding of the Royal Society, and this fact undoubtedly contributed to the rapidity with which science and technique developed in England.

The Value of Forests

THE value of forests to mankind in their beneficial influence on climate and the protection they exert against erosion, flood disasters and the man-made desert has come to the fore of recent years as one of the serious questions of present-day administration and civilization. It has been recognized that in both the Old and the New Worlds the results of the ignorant interference with the world's formerly existing and widespread forests and the failure to understand Nature's laws and the equilibrium she maintains when left alone has resulted in the past, and is resulting at the present day, in disasters of unforeseen magnitude. In a study of the past, India can show many instances of the results of interference with Nature's delicate balance between the forest, grassland and water supplies, and in that country, as a result of seventy years of forest conservancy, the lesson of the importance of the forests to the country has been grasped to some extent by her administrators. Even the people in some localities have become aware of the value of their local forests. The wireless has now come to the assistance of the Forest Department in making this value, for varying reasons in varying localities differing in configuration, elevation, aspect and climate, generally known to the people chiefly concerned, and including the town-bred population. The *Indian Forester* (63, No. 8; 1937) reproduces a radio talk on forests and climate given by Sir Gerald Trevor, inspector-general of forests, from Delhi. Those with a knowledge of the Indian district and its methods of administration in the past will appreciate to the full the significance of the enormous stride from the past which such a method of forest propaganda foreshadows.

Forestry in Sweden

AN interesting historical study by Lars Tirén of forestry conditions in the Degerfors district of the province of Västerbotten has recently been published (*Rep. Swedish Inst. Exp. Forestry*, No. 30. Centraltryckeriet, Esselte A.-B., Stockholm). The foundation upon which the paper is based is drawn from the work of the Forestry Research Institute in the Kulbäcksliden research forest situated in the above-mentioned region in the north of Sweden at an altitude of 160–320 metres. The history of the forest area has been traced back to the coming of human beings into north Sweden in the form of a Nordic stone age people who immigrated soon after the inland ice had receded from Vasterbotten 8,000 years ago. This race had, as fishermen and hunters, already spread widely in the region by about 2,000 years B.C. The progress in development of the people is traced, and with this development the inevitable effect on the forests of the region. The influence on the forest of fires, especially the great fire of 1694, is traced, and the contrast made between the area affected by this great fire and the forest which escaped. Not the least informative parts of the paper are those dealing with tar production and potash manufacture. The production of tar in Sweden goes back to very olden times. It was known in Viking days, and tar was exported in the thirteenth century. In the seventeenth century for long periods the export amounted to 70,000–80,000 barrels annually. In the region here specially dealt with, tar production was an important article of export. Hardwoods are used in potash manufacture, and here again the industry is a very old Swedish one in which the peasantry take a prominent part.

The Fairbridge Farm Schools

The story of Kingsley Fairbridge's life-work was told at a meeting of the Royal Society of Arts on February 1 by the Hon. Sir Hal Colebatch, Agent-General for Western Australia, who, as a member of the Western Australian Government, saved the original Fairbridge Farm School from collapse during the Great War by arranging for a State subsidy for it. It had at first been financed wholly from private subscriptions raised by the Child Emigration Society which Fairbridge formed in 1909 while an Oxford Rhodes scholar. The purpose of the scheme was, and is, to take from unpromising if not hopeless surroundings children of 7–12 years of age and give them a good general education with special training in all phases of farm and domestic activity, up to the age of sixteen years. Their subsequent careers are self-chosen. Many do not choose farm work, but their farm training is none the less valuable to them. The Farm School method involves: residence in a cottage home restricted to fourteen inmates (boys or girls) controlled by a carefully selected house-mother, training combined with teaching, provision for leisure time occupations, an elaborate 'after-care' system, including the banking of half of all earnings up to the age of twenty-one years. Judged by results, as represented by some 700 ex-pupils, all self-respecting self-supporting citizens, pulling their full weight in the community, the scheme has been an outstanding success. Similar schools have now been founded in Canada, Victoria and New South Wales. By the end of next year, the four schools should be in full operation with an aggregate enrolment of nearly 1,200 and an annual intake and outflow of 250, the total cost per head being about £50 a year.

Accessions to the British Museum (Bloomsbury)

AMONG accessions to the British Museum (Bloomsbury) reported at the April meeting of the Trustees are two which are of outstanding interest on the history of cultural development in Great Britain. Of these the earliest and from its unique character the more arresting comes from a bronze age burial on the north Yorkshire moors. In Loose Howe, a barrow overlooking Rosedale, excavated by Dr. and Mrs. Frank Elgee, was found a coffin consisting of two canoes, with a third canoe beside it. A bronze dagger associated with this burial afforded evidence of date; but the barrow also contained secondary burials, with one of which was a polished stone axe-hammer of Danish type. Canoe-burial is a new feature in archæology. The canoes had fresh bark on them and evidently had been made expressly for the burial, pointing to a hitherto unknown ritual of canoe-burial. It has been suggested that such canoe-burials may have given rise to the custom of coffin burial, typical in northern England and Denmark. In view of the conservatism characteristic of later maritime forms and custom in Scandinavia, the comparison with the ship-burials of a much later period inevitably is also suggested. These antiquities are on loan to the Museum by Captain A. W. Milburn. The second object of special interest is a stud ornamented with *millefiori* enamel, found at Chesterholme (Vindolanda) in Northumberland in an early fourth century deposit. It has been given by Mr. Eric Birley. It is the only example of *millefiori* of a late Roman date as yet found in Britain. It is thought that it may, on further study, provide a link with post-Roman Celtic enamels. Bronze objects belonging to the first Babylonian dynasty, *circa* 2000 B.C., are additions to examples of the art of a period at present poorly represented in the Museum. They are a bronze bar decorated with a ram's head, and three small figures of women. It is probable that they come from sites near the Diyalah River in Iraq.

Meteorological Observation in Certain British Colonies

It may be within the recollection of many readers of Nature that the period August 1, 1932–August 31, 1933, was chosen as the Second International Polar Year, during which meteorological observations were to be made at as many places as possible in both arctic and antarctic regions in furtherance of the study of world meteorology. Since the First International Polar Year, fifty years earlier, attention had become directed more to the problem of the exchange of air between equatorial and polar regions, and for that reason corresponding observations were required from middle and lower latitudes. The Governments of several British Colonies have published the special observations made within their areas, and the Meteorological Office, Air Ministry, is supplementing these with the publication of the observations made at a number of places not included in the above-mentioned Colonies, namely, Ascension Island, St. Helena, South Georgia, Falkland Islands, Ocean Island and British Somaliland. These summaries constitute Geophysical Memoir No. 73 of the Meteorological Office (H.M. Stationery Office. 4*s*. 6*d*. net). Monthly summaries of daily observations of the meteorological quantities most commonly observed are given in tabular form. These are supplemented by hourly readings in a few instances and by records of autographic instruments. The memoir contains no indication of the results of the undertaking as a whole, being only part of the observational material that is becoming available for students of the atmospheric circulation of the globe.

Telephone Circuit Noise Meters

Mr. H. R. Harbottle of the Post Office Research Station read a paper on February 4 to the Institution of Electrical Engineers describing an instrument for measuring the disturbing effect of induction from power lines on telephones. During a meeting of the Commission Mixte Internationale held at Dollis Hill, the delegates made comparative measurements of four different types of disturbances by the American, German and valve voltmeter methods. It was agreed that the last-mentioned should be developed and that the precise specification for the actual instrument should be determined by the Comité Consultatif Internationale (the C.C.I. for telephonic communications at great distances). It has been agreed internationally to call an instrument of this type a psophometer. The latest proposals are explained by the author. He states that from comparative measurements of the induction from the Midi Railway, which is supplied with power through mercury arc rectifiers, to the overhead communication lines of the French administration, the results obtained by using the psophometer fully justify this method of making noise measurements. The British Electrical and Allied Industries Research Association has published a pamphlet *M*/*T* 38 describing the method of constructing a psophometer. About a year ago, a commercial model on similar lines was constructed by the General Electric Co. at Coventry. Others have been made by Siemens and Halske in Germany, by the Administration and Ericssons in Sweden, by Standard Telephones and Cables in England and by the American Telephone and Telegraph Co. At the same meeting, a paper by Dr. A. H. Davis entitled "An Objective Noise Meter for the Measurement of Moderate and Loud, Steady and Impulsive Noises" was also read. The difficulties experienced were surmounted by adopting a technique in which the noise and the reference note are listened to alternately.

Carnegie Trust for the Universities of Scotland

The circumstances of the origin of the Trust are recalled in its recently published report for the year 1936–37. Referring to the passing of Lord Craigmyle, formerly one of the trustees, the report quotes a passage from Mr. Carnegie's autobiography which shows that it was an article contributed by the former to the *Nineteenth Century* magazine in 1897 that led to the idea of a gift of ten million dollars—"half of the yearly revenue from it to be used to pay the fees of deserving poor students and the other half to improve the universities". Last year the Trust devoted nearly £52,000 to the payment of fees of deserving poor students—2,637 men and 897 women. Voluntary refunds of fees advanced by the Trust in previous years, that is, since 1901, amount to nearly £40,000, namely, £25,000 by 569 men and £14,500 by 454 women. Women beneficiaries would seem to be more given to expressing their gratitude in this way than men. Expenditure on post-graduation fellowships, scholarships and grants for research amounted to £17,500. Resignations of fellows and scholars for the purpose of entering upon professional careers were numerous—a sign, perhaps, of reviving prosperity. This was specially noticeable in the field of chemical research. Of thirty-four fellows and scholars in this field, thirteen were absorbed into industry before the termination of their grants.

Mauritius Plants

THE flora of Mauritius is of great interest on account of the geographical position of the Mascarenes, their relation to the great land masses of the Old World and the high endemism of the species. Unfortunately, the remnants of the original vegetation are fast disappearing. It is therefore very necessary to obtain adequate and critical herbarium material upon which must depend the advancement of knowledge of the flora. A complete list of the flowering plants in the herbarium of the Mauritius Institute, compiled by R. E. Vaughan, forms the subject of the first part of a new publication (*Mauritius Institute Bulletin*) dealing with the taxonomy and ecology of the flora and fauna of the Mascarenes. About eight hundred species are listed, many of which are introduced weeds. Attention is directed to the urgency of acquiring additional material in many of the more interesting genera such as *Eugenia*, *Diospyros* (ebony) and *Tambourissa*, at present inadequately represented in the collection. Further material is also required of the native orchids, of which there were probably more than eighty species in the island, though many have already become extinct owing to the destruction of the large trees on which they were epiphytic.

Fusible Metals

IN No. 5, Series B, of the Technical Publications of the International Tin Research and Development Council, E. J. Daniels summarizes existing knowledge of the fusible metals containing tin. The mechanical and creep properties of these materials are dealt with, together with their 'castability', corrosion and applications. Among the latter are mentioned their uses in automatic safety devices for fire alarms, etc. as solders and seals, for making foundry patterns and for the production of hollow bodies by electrodeposition, as fillings for thin-walled tubes to prevent buckling during bending, as tempering baths for steel tools, as matrix alloys for mounting dies and punches, for the metallization of wood and for a number of research purposes.

Special Libraries and Information Bureaux

THE report of the proceedings at the fourteenth Annual Conference of the Association of Special Libraries and Information Bureaux at Cambridge last September has now appeared. It contains full reports of the discussions on technical translating, and the uses of micro-photographic processes in documentation, as well as the other papers given at the Conference, including one by Mr. B. M. Headicar containing a number of practical notes on the storage of pamphlets and the preservation and restoration of books and documents. In addition to its value as a permanent record of the proceedings at the Conference, the report indicates the wide range of interests of A.S.L.I.B.

Science Abstracts

THE volume for 1937 devoted to physics has 1,504 pages, covering 5,494 abstracts, a subject index of 215 pages, an apparatus and instrument index of 24 pages and an author index of 78 pages. The volume for electrical engineering has 934 pages, 3,252 abstracts, a subject index of 121 pages and an author index of 48 pages. In pages and abstracts each volume is about 7 per cent less than that for 1936, but continues to be indispensable to research workers and all who wish to keep up to date in the subject with which it deals. The system of indexing in the physics volume greatly facilitates quick and easy reference.

Rabbit Control in Australia

ON Wardang Island, which lies to the west of Yorke Peninsula in South Australia, a field test is now in progress of the virus of myxomatosis, as an agent in reducing rabbit population. The marked specificity of the disease to the European wild rabbit (*Oryctolagus*) and its retention of virulence after passage through many hosts make it well worth trial in a country where rabbits constitute a pest ever-present, though varying in intensity. The test is on a small infested area of some ninety acres under strictly controlled conditions.

Grocers' Company Scholarship

THE Grocers' Company is offering a scholarship for the encouragement of original medical research into the causation of prevalent diseases or as to means of preventing premature death. The award, which is tenable for two years from September 1, is £300 for the first year and £450 for the second year, in addition to which the Council will grant up to £150 a year towards the cost of special apparatus required by the scholar. Candidates should not be more than thirty-five years of age and should send their applications to the Clerk, Grocers' Company Hall, London, E.C.2, before May 1.

Two Astronomical Handbooks for 1938

FLAMMARION'S "Annuaire Astronomique" is a remarkable little handbook, and those responsible for it evidently take great pains that it shall include the latest information on astronomical data. For example, the list of double star orbits contains the latest ones published. A note is given by Lyot on the transit of Mercury, on June 24, 1937, across the sun's corona; the list contributed by Störmer of auroras seen from Norway is continued as far as October 1, 1937, and there are some new geophysical data comprising sudden radio fadings observed from November 26, 1936, to July 1, 1937. The utility of this handbook to the novice is illustrated by the three maps showing the star field of the variable star, o (Mira) Ceti, as seen respectively with the naked eye, a pair of binoculars, and a moderate-sized telescope. The "Anuario" of the Astronomical Observatory of Madrid contains information that is chiefly of use to those living in Spain or in adjacent latitudes. There are, however, other astronomical tables and explanations (in Spanish) of general interest. A short description is appended of graphical solutions of spherical triangles used in problems of positional astronomy.

A Large Sunspot Group

On April 8, a pair of large sunspots, with smaller attendant spots, came into view around the sun's north-east limb. The group crossed the sun's central meridian on April 14·1 U.T. and will reach the western limb on April 20. The latitude of the group is 27° north, and its area on April 8 was 1,500 millionths of the sun's visible hemisphere. Sunspots of this size are found to show, statistically, a marked association with the occurrence of terrestrial magnetic storms, the storm commencing on the average about one day after the time of central meridian passage of the associated sunspot.

Announcements

The Kelvin Medal Award Committee announces that the Kelvin Medal for 1938 has been awarded to Sir Joseph J. Thomson, and that the presentation will be made by Lord Rayleigh in the Great Hall of the Institution of Civil Engineers, on Tuesday, May 3, at 5 p.m.

Dr. W. T. Calman, formerly keeper of zoology in the British Museum (Natural History), has been elected an honorary member of the Société Zoologique de France.

The following have been elected associates of the Royal Astronomical Society: M. L. d'Azambuja, Meudon Observatory, France; Prof. A. O. Leuschner, director of the Students' Observatory, Berkeley, California, and professor of astronomy in the University of California; Prof. Knut Lundmark, director of the Lund Observatory and professor of astronomy in the University of Lund.

M. Robert Courrier has been nominated professor of experimental morphology and endocrinology at the Collège de France.

Lieut.-Colonel J. H. M. Greenly has been appointed president of the Institute of Fuel in succession to Sir Philip Dawson, as from October 13 next. Colonel Greenly, who has been a vice-president of the Institute for the past few years, is the chairman of Messrs. Babcock and Wilcox, Ltd.; he is also a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, and chairman of the British Non-Ferrous Metals Research Association.

The following appointments and promotions have recently been made in the Colonial Service: K. M. Francis, European assistant, East African Meteorological Service, East Africa; J. P. Henderson, European assistant, East African Meteorological Service, East Africa; R. G. Ffoulkes-Jones, second assistant petroleum technologist, Trinidad; R. R. Waterer (assistant conservator of forests), conservator of forests, Cyprus; W. E. Bassett (assistant agricultural officer, Agricultural Department, Dominica), curator, Agricultural Department, Montserrat, Leeward Islands; C. J. M. Krige (senior agricultural assistant), agricultural officer, Tanganyika.

The annual Conference of the Institute of Public Cleansing will be held in Glasgow on June 13–17.

The eighth International Congress for Logopædics and Phoniatrics will be held at Salzburg on July 28–30. Further information can be obtained from the president, Ferstelgasse 6, Wien ix.

The eighth Netherlands Indies Congress of Natural Science will be held at Soerabaja on July 20–23 and will consist of sections devoted to mathematics, natural history, physics, medicine, biology, chemistry, veterinary science, geology and geography. Further information can be obtained from the general secretary, Dr. H. W. Lubberhuizen, Embong Kemiri 4, Soerabaja.

The seventh International Congress of Entomology will be held in Berlin on August 13–20, and will consist of a general section and a special section, the latter comprising a subsection of medical and veterinary entomology. The president will be Prof. E. Martini of Hamburg. Further information can be obtained from the general secretary, Dr. Hering, Zoologisches Museum, Invalidenstrasse 43, Berlin, N.4.

A health congress of the Royal Sanitary Institute will be held at Portsmouth on July 11–18 under the presidency of Lord Bessborough. Sections will be allotted to preventive medicine, architecture, town planning and engineering, maternity and child welfare and school hygiene, veterinary hygiene, national health insurance, hygiene of food, and tropical hygiene. Conferences of local authorities, medical officers of health, engineers, surveyors, sanitary inspectors and health visitors will also take place during the Congress. Further information can be obtained from the Secretary of the Institute, 90 Buckingham Palace Road, S.W.1.

We have received a copy of the complete, official list of the British papers which are being prepared for presentation at the sectional meeting of the World Power Conference to be held in Vienna on August 25–September 2. Copies of the technical programme may be obtained now, and copies of the general programme, time-table and membership application form will be obtainable in due course, from the British National Committee, World Power Conference, 36 Kingsway, London, W.C.2.

Erratum. In the article "Scientific Work of the Drifting North Polar Station" published in Nature of April 9, pp. 629–632, it should have been stated that the distances quoted in English units were in nautical miles. On p. 629, col. 2, line 4, the distance covered by the drift was 1,134 nautical miles (2089 km.); line 11, the average drift of the floe was 9·1 km. (4·9 nautical miles) a day; line 15, the daily drift was sometimes 23 nautical miles (42 km.) a day.

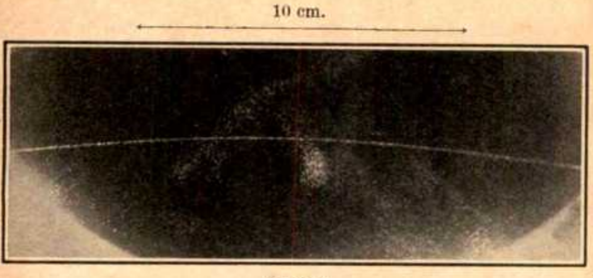
Heavy Electrons in Cosmic Rays

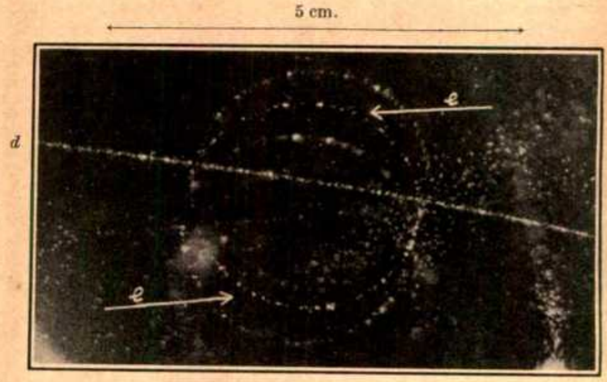
Neddermeyer and Anderson[1], on the basis of their experiments on the loss of energy by cosmic ray particles, have suggested that there are present in cosmic rays 'new' particles of mass greater than that of an electron and less than that of a proton. In this note we give additional evidence for such a particle (some of which has previously been reported by one of us at the Conferences on Physics in Copenhagen and Moscow in September 1937, the report at the latter being published), of a type which has also been put forward by other workers since the appearance of Neddermeyer and Anderson's paper.

The object of the present experiments was to investigate the nature of cosmic ray particles by measuring the primary ionization per centimetre along their tracks using the Wilson cloud chamber method, with a magnetic field to determine the momentum of the particles. The results of the early observations of Kunze[2] on this effect had led one of us to suggest that cosmic ray particles of high energy are predominantly protons, those of low-energy electrons[3]. It was expected that further observations in the region of 10^8 'volts' would throw some light on the situation. In our experiments the method of random expansions is used as it is desirable to have sharp tracks for the purpose of counting the primary ions, the tracks in a counter-controlled chamber being of necessity somewhat diffused. With a large chamber (30 cm. diameter, 30 cm. deep) about 10 cm. of sharp cosmic ray track was recorded on every photograph.



Track *d*.

In the first two hundred photographs, taken with a field of 1,000 gauss in the chamber, three tracks were observed (we shall refer to them as *a*, *b*, and *c*) the specific ionization of which was considerably greater than that of an electron track of the same curvature (that is, momentum), while a proton track with the same ionization would have a much smaller curvature and would in fact be nearly straight. It was concluded that if the curvature was due to the magnetic field, and not spurious, the tracks could only have been produced by a new particle of mass between that of an electron and a proton. A spurious curvature can be due to optical defects or to distortion of the track by motion of the gas in the chamber. The optical distortion was negligible. As regards the effect of air motion, tracks *a* and *b* passed through after the expansion and their curvature could scarcely have been spurious, judging from the straightness of sharp electron tracks appearing in the same series of photographs. At this stage of our work the paper by Neddermeyer and Anderson appeared which proposed on different grounds the type of particle which these tracks had suggested to us.



Tracks *e*, with *d* (across centre of photograph) superimposed.

To reduce the doubt regarding the curvature we increased the magnetic field from 1,000 to 2,200 gauss, but in the following four hundred photographs no heavy tracks of appreciable length appeared. The work was recently resumed using a mixture of 50 per cent hydrogen and 50 per cent air in the chamber. The greater separation of the ions occasioned by the hydrogen enables a more accurate count of their number to be made, so that smaller departures of the specific ionization from the normal could be detected. In one of the photographs taken in this series there appeared the track which is here reproduced (track *d*). The number of primary ions per centimetre along this track is about three times greater than that along an electron track of the same curvature, while a proton with this ionization would have a curvature about ten times less. In this case we are convinced that the curvature cannot have been produced by air motion. Photographs taken in the same 'run' happened to have tracks of fast particles in the same part of the chamber and these showed that spurious curvature was not more than about one twentieth of the curvature of the track *d* (the radius of curvature of which is about 55 cm.). Moreover, the spurious curvature was in the opposite direction to that of the latter. Old tracks passing through before the expansion showed obvious distortion, but even for these the extent of the corresponding spurious curvature was small and again in the opposite direction to that of the heavy track. As regards the specific ionization, we reproduce here the track of a $0{\cdot}5 \times 10^6$ volt electron (track *e*) taken under the same conditions as *d*, a part of which is superimposed on the same photograph for purposes of comparison. If *d* was the track of an electron it should have about the same number of ions per centimetre as *e*, while actually it is seen to have many more.

In the accompanying table, we give the details of each of the four tracks referred to, together with the estimated mass. The momentum in column (4) is given in terms of *mc*, where *m* is electron mass, and the ionization in column (3) is expressed in terms of the observed ionization for million-volt electrons. The sign of the charge of the particle, assuming downward motion, is given in the last column. Apart from track *b*, the tracks indicate a consistent mass of nearly 200 times electronic mass.

Track	$H\rho$ $\times 10^{-5}$	Ionization	Momentum (unit, *mc*)	Velocity (unit, *c*)	Mass (unit, *m*)	Sign of Charge
a	1·10	5	65	0·30	220 ± 50	−
b	1·83	>7	107	< 0·25	>430 (<800*)	+
c	1·47	3·0	86	0·45	190 ± 60	+
d	1·15	3·3	67	0·41	160 ± 30	+

* This limit is set by a minimum range equal to the observed length of track in the chamber.

As we have already stated, evidence of the type presented here has also been found by other workers. The results obtained by Street and Stevenson[4], and by Ruhlig and Crane[5] require a particle with a mass in satisfactory agreement with that required by the tracks *a*, *c* and *d* above. However, those of Nishina, Takeuchi and Ichimiya[6], and of Corson and Brode[7], require an appreciably bigger mass which is comparable with the mass indicated by the track *b*. It is, however, possible that the track *b* in our experiments was produced by a proton, the observed curvature being partly spurious. It might also be mentioned that in our experiments, in addition to the tracks referred to above, three or four heavily ionizing tracks were observed which were obviously due to protons.

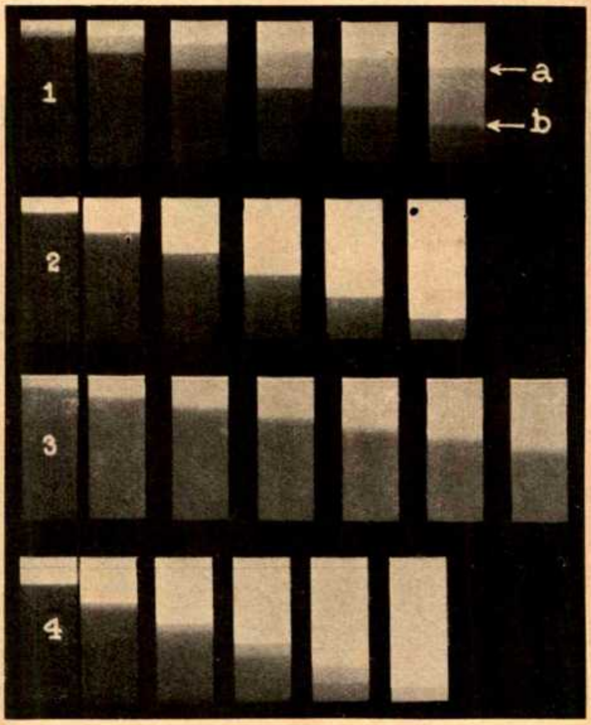
The Ultracentrifugation of the Proteins of Cucumber Viruses 3 and 4

Cucumber mosaic viruses 3 and 4 of Ainsworth[1] have many properties in common with tobacco mosaic virus, in spite of the fact that they do not cause disease when inoculated to tobacco plants. They are sufficiently stable so that their virus proteins have been isolated chemically[2]; these proteins resemble the tobacco mosaic virus protein in optical characteristics when in solution, in high inactivation temperatures, in the X-ray diffraction patterns[3] they produce, and in serological reactions. We have carried through ultracentrifugal isolations of the cucumber virus proteins and have found that they are also like tobacco mosaic virus protein in sedimentation rates.



SEDIMENTATION ABSORPTION PHOTOGRAPHS. EXPOSURE, 1·5 SEC. MADE EXACTLY 5 MIN. APART, USING ULTRA-VIOLET LIGHT OF WAVE-LENGTHS BETWEEN 2700 A. AND 2300 A.

1. AQUEOUS SOLUTION OF PELLET OBTAINED BY ONE PROLONGED ULTRACENTRIFUGATION OF THE JUICE OF CUCUMBER PLANTS DISEASED WITH CUCUMBER 4 VIRUS. The molecular component producing boundary (*a*) is present in both healthy and diseased plant juice, that responsible for (*b*) is found only in the juice of virus-diseased plants. Centrifugal field at the mid-point of the analytical cell, 23,780 times gravity.

2. SALINE SOLUTION OF CUCUMBER 4 VIRUS PROTEIN PURIFIED FROM THE LIGHTER MACROMOLECULES BY FRACTIONAL ULTRACENTRIFUGATION. The sedimenting boundary corresponding to (*b*) of 1 is single and sharp. Mean centrifugal field, 30,690 times gravity. A photograph of the purified cucumber 3 protein is indistinguishable from this one.

3. SOLUTION OF THE MACROMOLECULES PRESENT IN THE JUICE OF HEALTHY CUCUMBER PLANTS. This boundary moves at the same rate as (*a*) of 1. Mean centrifugal field, 31,290 times gravity.

4. SALINE SOLUTION OF THE CUCUMBER 3 VIRUS PROTEIN AFTER SEVERAL ULTRACENTRIFUGAL PRECIPITATIONS. The upper boundary corresponds to (*b*) of 1, the lower has a constant of about 200×10^{-13} cm. sec.$^{-1}$ dynes^{-1}. Mean centrifugal field, 31,660 times gravity.

The method used in this isolation was essentially the same as that developed for the ultracentrifugal crystallization of the tobacco mosaic virus protein[4] and for the purification of several other less stable plant[5] and animal[6] virus proteins. Juices of plants infected with either of these viruses were found to contain two macromolecular substances giving sharp boundaries with the analytical ultracentrifuge. The more rapidly sedimenting boundary (*b* of photo.) is due to virus protein; the lighter component (*a*) is present in the juice of healthy as well as diseased plants. Purified solutions of the virus proteins have been obtained after two quantity ultracentrifugations[7], using saline for re-solution of precipitated protein and a time of centrifugation that would sediment only a negligible amount of the lighter component. Under the conditions of our experiments, the two heavy components were almost completely separated by applying a centrifugal field of 40,000 times gravity for not more than half an hour. The proteins of cucumber viruses 3 and 4 differ from unaltered tobacco mosaic virus protein in being practically insoluble in pure water. Saline dissolves them and facilitates the breakdown of traces of the smaller high molecular weight substances (corresponding to (*a*)).

Cucumber mosaic viruses 3 and 4 do not lend themselves so well to quantitative work as viruses giving necrotic local lesions. Nevertheless, Bawden and Pirie[2] have demonstrated that infectivity was concentrated in their chemically isolated virus protein preparations. Our heavier components are highly infectious and without doubt they are essentially the same as Bawden and Pirie's proteins. Fresh preparations of the proteins of cucumber viruses 3 and 4 give single sharp boundaries in the analytical ultracentrifuge (Photo. 2); their sedimentation diagrams are indistinguishable from each other and from that of unaltered tobacco mosaic virus protein[8]. As nearly as can be determined, these three proteins sediment at the same rate and thus probably have substantially the same molecular weights; sedimentation constants averaged from several closely agreeing photographs are $s_{20} = 173 \times 10^{-13}$ cm. sec.$^{-1}$ dynes^{-1} for the cucumber virus 3 protein, and $s_{20} = 175 \times 10^{-13}$ for the cucumber virus 4 protein. A recent determination[8] for the tobacco mosaic virus protein gave $s_{20} = 174 \times 10^{-13}$. Tobacco mosaic virus protein derived from plants infected for more than four weeks and purified by quantity ultracentrifugation with phosphate buffer as solvent shows[8] a second more rapidly sedimenting component with $s_{20} = 200 \times 10^{-13}$. Similar components (Photo. 4) were found in purified preparations of cucumber viruses 3 and 4 that were subjected to repeated ultracentrifugations.

Special interest is attached to the presence in cucumber plants of a homogeneous high molecular weight substance other than the virus protein. Purified solutions from either healthy or diseased plants sediment with a single fairly sharp boundary corresponding to $s_{20} = 77 \times 10^{-13}$ (Photo. 3). They have given the usual qualitative tests for proteins and have always had a clear chlorophyll-green colour. Water solutions can be kept in the icebox for several days; in saline, decomposition is more rapid. Considerable molecular damage follows repeated sedimentations in the quantity ultracentrifuge, but in this respect this macromolecular substance is not unique. When repeated ultracentrifugations were made of saline solutions of purified cucumber mosaic and tobacco mosaic virus proteins, the proteins were denatured and rendered insoluble.

As milder methods of extraction and purification have been introduced, there have been found an increasing number of apparently non-infectious heavy substances[9]. They are comparable with virus proteins in homogeneity and rate of sedimentation, in stability, and in concentration in tissues. It is reasonable to expect that their further study may throw light on the nature and the origin of the virus proteins.

Cosmic Rays and the Aurora of January 25-26

Between January 16 and 26, there occurred three violent magnetic storms; the storm of January 25 was accompanied by a magnificent aurora borealis which was visible nearly in all parts of Europe (see Nature, Jan. 29 and Feb. 5).

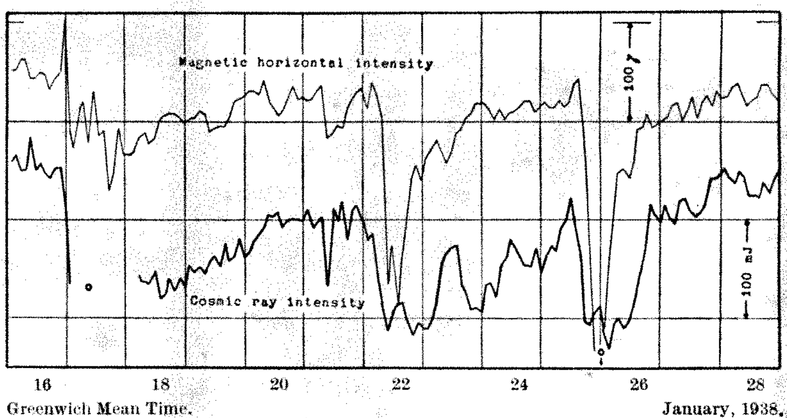

Fig. 1.

Two-hour mean values of the magnetic horizontal intensity and of the cosmic ray ionization during the magnetic and auroral disturbances of January 16–28, 1938. Average cosmic ray intensity, 2356 mJ. Average horizontal intensity 20,432 γ.

In 1937, during the severe disturbances from April 25 until April 30, S. E. Forbush[1] and two of the present writers[2] found from simultaneous registrations in North America, Peru and Central Europe, that cosmic ray ionization was influenced all over the earth by the magnetic storm, and that a sharp decrease of cosmic ray ionization followed a decrease of the magnetic horizontal force. A similar effect was also noticed by J. Clay[3] in Amsterdam.

This parallelism between the variations of the horizontal magnetic intensity and the cosmic ray ionization was observed once more and even more strikingly during the recent aurora and the two preceding magnetic storms mentioned above.

In the accompanying graph, the two-hour means of the magnetic horizontal intensity (as observed at the magnetic observatory, Vienna-Auhof, for which we are indebted to Prof. von Ficker) and the corresponding values of the cosmic ray intensity (from the registrations of the Hafelekar Observatory near Innsbruck, Austria, 2,300 metres above sea-level) are plotted together. The cosmic ray ionization was registered by means of a Steinke standard apparatus, completely screened from local radiations on all sides by iron (7 cm. thick) and lead screens (10 cm. thick). All observations are reduced to the same barometric pressure.

From inspection of the curves, it can be said that there is a very close parallelism between the variations of *H* (magnetic horizontal force) and *J* (cosmic ray ionization). The correlation coefficient as calculated from the curves is + 0·72.

On the day of the aurora (January 25) the ionization decreased from noon to 4 h. a.m. of the following day by 170 m*J* (= 0·170 *J*), that is, by about 7 per cent. Then an increase of the same amount followed, and on the evening of January 26 both *J* and *H* were quite normal. The recovery of *J* occurred some hours later than that of *H*, and this was also noticed after the disturbance of January 22.

During the magnetic storm in the night of January 16–17, the decrease of the cosmic ray ionization amounted to 5·7 per cent within the first five hours; the further decrease could not be measured since the image of the electrometer fibre disappeared from the field of view. For the sake of comparison, it may be said that on magnetically undisturbed days the average deviation of the hourly values of *J* amounts to not more than ± 0·62 per cent.

From our observations shown in the diagram, it was calculated by Charlier's method that on the average the variation of the ionization was 0·82 m*J* for a change in the magnetic horizontal intensity of 1γ (1γ = 0·00001 gauss). This magnetic effect corresponds to 0·3 per mille per γ. During the magnetic storm in April 1937, Hess and Demmelmair[2] found an effect of the same order of magnitude (1·4 m*J* per γ) and from the correlation of daily mean values in periods when the correlation is positive a similar effect was calculated by us in our last publication[4].

The effect of the variation of *H* during magnetic and auroral disturbances on the cosmic ray ionization can be explained by the assumption of corpuscular ring currents encircling the earth at distances of a few earth radii and supplied by solar eruptions (S. Chapman[5]). If during a solar outburst these ring currents are increased, the magnetic dipole moment of the earth is strengthened for regions outside these rings or shells, while inside, near the surface of the earth, the magnetic field is reduced. The increase of the magnetic field in outer space causes a considerable deflection of the normal paths of the cosmic ray particles, thus reducing the observed cosmic ray intensity on the earth.

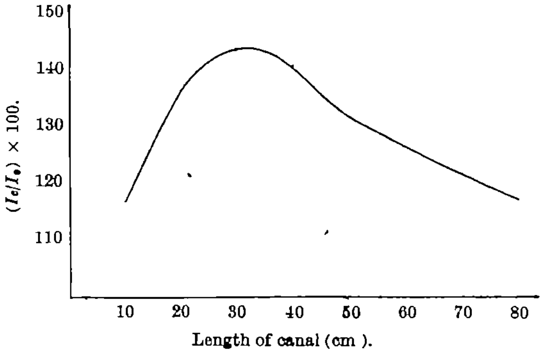
Canalization of Gamma Rays

IN an earlier communication from this laboratory[1] a method of canalizing neutrons was described which made it possible to investigate the action of these particles at distances of a metre and upwards from weak sources. In the interval, apparatus capable of producing powerful beams of neutrons and penetrating X- or gamma rays has been developed in many laboratories.

This has made it desirable to investigate the possibility of canalizing electromagnetic radiations, and we have carried out such an investigation for the gamma rays from radium (B + C). For these measurements we have used the radiations from one, to ten or more, milligrams of radium filtered by 0·5 mm. of platinum, and canalized them by tubes of wax, lead, zinc, iron, etc., having lengths from 10 cm. to 1 m. and of varying wall thickness.



The ratio of the intensity of the canalized beam (I_c) to that of the direct uncanalized beam (I_0), is shown in the accompanying figure for iron canals of various lengths; the ionization being measured by a thin-walled ionization chamber. The internal and external diameters of these tubes were 70 mm. and 78 mm. respectively. Fuller details of these experiments, including the effects of varying the wall thickness of the ionization chamber, will be published elsewhere.

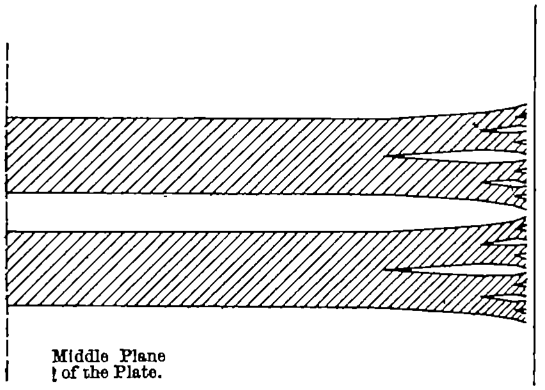
The Intermediate State of Supraconductors

In a previous paper[1], I have shown that a body in the so-called 'intermediate' state consists of alternating layers of the supraconducting and normal phases. It can be shown, however, that the plane-parallel form of these layers discussed in this paper does not correspond to a minimum of the free energy*. A detailed investigation leads to the result that the thickness of the layers does not remain constant throughout the body, but is greatest in the inner part, and becomes very small near the surface of the body. The accompanying figure shows a section of a plate in a transverse magnetic field. The normal layers (shaded in the figure) branch in both directions towards the surface of the plate. A similar branching along the lines of force occurs in the intermediate state of a body of any other shape.



Calculation shows that the thickness of the layers in the middle of the body is of the order of magnitude $(l_0 l^2)^{1/3}$, l being the total length of the line of force inside the body and l_0 the depth of penetration of the magnetic field in a supraconductor (probably of the order 10^{-5} cm.).

The branching of the layers towards the surface continues until the thickness of the layers becomes of the order of magnitude of l_0, when it is no longer really possible to speak of the normal and supraconducting states as distinct phases. Hence, a region of the width l_0 near the surface of the body is not in the intermediate state, that is, does not consist of layers; but is in some different state which may be called the 'mixed' state.

The conception of the alternating layers leads to the conclusion that the intermediate state must be supraconducting in the direction of the magnetic field, but has resistance in perpendicular directions. It might seem that the body should be supraconducting also in the direction which is parallel to the layers but perpendicular to the direction of the field; however, it can easily be shown that, if the current is flowing in this direction, the layers turn so as to be perpendicular to the current.

For the resistance of the intermediate state perpendicular to the magnetic field, we should have $R = R_0 \dfrac{B}{H_c}$ (B, magnetic induction; H_c, critical field; R_0, resistance of the normal state). However, experiment shows[2] that the resistance of a wire in a transverse field tends to this value only if the current is comparatively large, the resistance for very small currents being much smaller. This indicates that an appreciable part of the current flows not in the middle of the wire through the intermediate state, but in the mixed state near the surface. More detailed experiments could in this way supply information about the properties of the mixed state, about which at present very little can be said theoretically.

The detailed calculations will appear elsewhere.

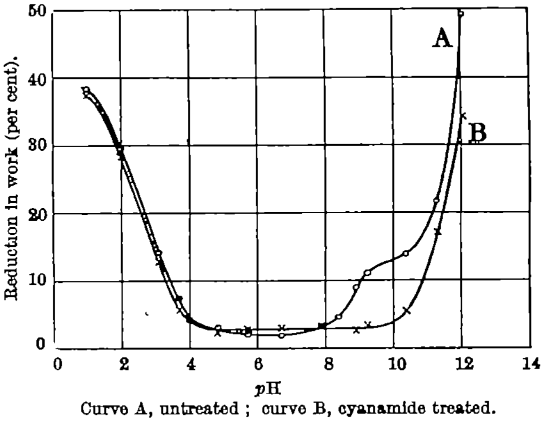
Action of Cyanamide on Wool

When wool fibres are exposed to the action of light and air, the cystine linkages undergo decomposition with loss of sulphur and development of sulphydryl and aldehyde groups. In consequence, the increased alkali-combining power of the exposed tips, as compared with the unexposed roots of wool staples above *p*H 8, has been referred to the presence of excess sulphydryl groups in exposed wool[1]. On treatment with cyanamide, however, sulphydryl compounds are converted into derivatives of isothiourea[2], and the *p*H-stability region of exposed wool, which normally ranges from *p*H 5 to 7 in buffer solutions, should be capable of extension to *p*H 10 by treating the wool with cyanamide, especially as the amino groups of lysine side-chains are simultaneously converted into more strongly basic guanido groups[3].

The truth of this deduction has been established by comparing the elastic properties of untreated and cyanamide-treated exposed wool in buffer solutions of varying *p*H. Fibres from the middle portion of a Cotswold wool staple were purified by successive extraction with alcohol, ether and distilled water, and a curve illustrating the reduction in their resistance to 30 per cent extension at 22·2° C. in buffer solutions of varying *p*H, as compared with water at *p*H 5·5, is given in the accompanying figure. The increased ease of extension between *p*H 8 and 10 is due to the fibre-swelling which follows combination of sulphydryl groups with alkali. When, however, the fibres had been treated with a 10 per cent cyanamide solution for 47 hours at 22·2° C., their resistance to extension was independent of *p*H between *p*H 5 and 10, as shown in the figure, owing to the conversion of cystein side-chains into corresponding isothiourea derivatives. The extent of the *p*H-stability region of cyanamide-treated wool, which has been confirmed by comparing the titration curves



Curve A, untreated; curve B, cyanamide treated.

of untreated and cyanamide-treated wools, lends further support to the salt-linkage hypothesis[4].

In conclusion, it should be noted that the enhanced reducing power of exposed wool is minimized by cyanamide treatment, and the industrial significance of this aspect of the cyanamide reaction has been investigated in conjunction with other workers and Imperial Chemical Industries (Dyestuffs Group), Ltd.[5].

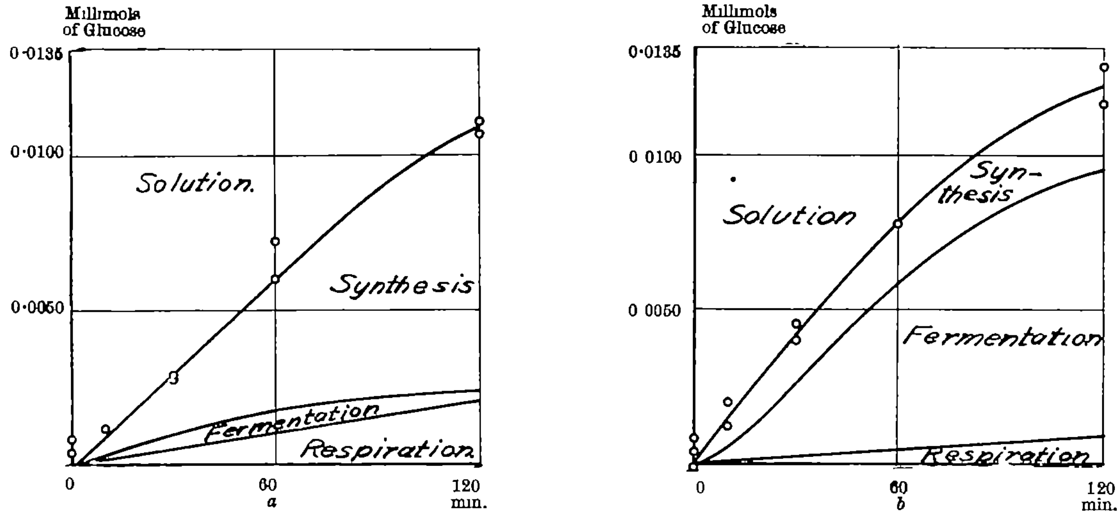
Action of Cystein on Respiration, Fermentation and Synthesis in Yeast Cells

Quastel and Wheatley[1] have demonstrated that cystein and glutathione promote the ærobic fermentation in baker's yeast. Cystein inhibits very strongly the respiration in this material. We have confirmed these results for a Swedish baker's yeast[2]. In our experiments, carried out generally at 30° and pH 5, the concentrations of glucose as well as those of cystein have been greatly varied. In higher concentrations of glucose alone (0·027–0·108 m.mol per 2·4 c.c. suspension containing 20 mgm. fresh yeast) the rate of ærobic fermentation is low at the beginning of the experiment but increases soon considerably. High concentrations of glucose give an effect similar to that following the addition of cystein to lower concentrations of glucose. In presence of cystein, however, the rapid ærobic fermentation starts immediately upon the addition of glucose. In the absence of cystein fermentation comes to an end, giving place to a slow respiration. The amount of carbon dioxide formed through ærobic fermentation is directly proportional to the concentration of glucose. The maximum rates of fermentation are directly proportional to log (glucose), range tested: 0·00455–0·108 m.mol per 2·4 c.c. suspension. During the period of rapid ærobic fermentation the added cystein is partly oxidized. The quotient total CO_2/O_2 decreases fairly rapidly during the period of ærobic fermentation. The mean of the total CO_2/O_2 values during the period of ærobic fermentation is directly proportional to log (cystein), or in other words, to the oxidation reduction potential of the cystein solution (cf. Dixon and Quastel[3]). The range tested was 0·0002–0·005 m.mol cystein per 2·4 c.c. suspension.

In medium and lower concentrations of glucose (0·0045–0·027 m.mol per 2·4 c.c. suspension) the respiration and the (slight) ærobic fermentation comes to an end when about 40–45 per cent of the added glucose has been broken down. Estimations by adding fresh yeast or by the orcin method[4] demonstrate that practically no glucose is left in the solution surrounding the yeast cells. As is well known[5], the yeast synthesizes glucose to higher carbohydrates. When cystein is present, all the added glucose is broken down. The higher carbohydrates are not formed or, possibly, they are not stable. All the glucose rapidly taken up by the cells is available for the breakdown processes. The graphs give representative experiments with and without cystein.



Consumption of glucose by baker's yeast through respiration, fermentation and synthesis of higher carbohydrates at 15° C. (*a*) Without cystein; (*b*) With 0·005 millimols of cystein added to 2·4 c.c. cell suspension of 20 mgm. yeast in a buffer, succinic acid and succinate, pH 5. Initial amount of glucose: 0·0135 m.mol.

The synthesis is considerably lower under anærobic than under ærobic conditions. The rate of respiration is, over a very wide range, independent of the concentration of glucose, but decreases very rapidly with increasing concentrations of cystein.

Baker's yeast which has been kept in a dried state exhibits qualities very similar to those described for fresh yeast treated with cystein. The respiration is comparatively low; the ærobic fermentation considerable. Further, the capacity for synthetic storage of glucose is impaired. This can be changed very considerably by aerating the yeast in the presence of glucose. Following the æration the respiration is increased, the ærobic fermentation strongly decreased and the capacity for synthesis restored.

The results reported may contribute to the discussions concerning the 'Pasteur reaction'. This reaction may be due to the mechanism causing storage of higher carbohydrates. The oxidation or reduction of certain systems decides whether synthesis or fermentative breakdown will occur in the cell. This interpretation combines in a somewhat modified form elements from the ideas presented by Meyerhof[6], Quastel, Wheatley[3] and Lipmann[7].

Forms of *Gammarus* from Ireland

THROUGH Miss Frost, of the Ministry of Fisheries, Eire, I have received a collection of *Gammarus* from the rivers and freshwater loughs of Ireland. This collection was sent in the hope that in waters of widely differing hydrogen ion concentration, some species other than *G. pulex* (L) might be present.

On examination, however, it became obvious that the collection did not contain a single specimen of *G. pulex*. The specimens were very distinctly the allied and usually brackish-water species *G. duebeni* Lilljeb.

This is a very astonishing fact, for though *G. duebeni* is known to range into fresh water, its occurrence there is by no means common. Also, *G. pulex* is the usual freshwater form which is found generally distributed in the fresh waters of Europe, although I have not found it in the waters of high acidity in Scotland.

The Irish collection was made from rivers and loughs all over the country and the *p*H varied from 4·8 (which incidentally produced an enormous specimen) to the strongly alkaline waters of the limestone districts.

By the courtesy of Dr. Harding I have also examined the collection of *G. pulex* from Ireland in the British Museum (Natural History) and find them to be *G. duebeni* with the exception of a few specimens of *G. pulex* from Lough Erne. These are the only *G. pulex* I have seen from Ireland.

These freshwater *G. duebeni* differ only slightly from the brackish-water form. There are fewer bristles among the groups of spines on the urosome. This is merely a matter of degree and it would be very difficult, if not impossible, to draw any definite distinction anatomically between this and the brackish-water form.

A full report will appear later.

Action of Insulin in Cell-free Extracts

IT has recently been reported that the Ostern reaction, the formation of hexosemonophosphate from glycogen and phosphate in muscle extract, is inhibited by glucose[1]. It was suggested it might be possible to correlate this phenomenon with known facts of carbohydrate metabolism *in vivo*. It can now be stated that an inhibition of glycogen breakdown in muscle extract can also be produced by adding minute amounts of insulin, the hormone which removes glucose *in vivo*. The same effect can be demonstrated using extract of dried yeast as enzyme. The esterification of phosphate in the Ostern reaction takes place in two steps; a non-reducing easily hydrolysable ester appears first, which is then followed by the irreversible formation of Embden ester. The second step is inhibited by insulin. The hormone, even if added at intervals, considerably retards the formation of Embden ester, but unlike glucose does not interfere with the eventual end point. It is known that *in vivo* the symptoms of hypoglycæmia, after vigorous insulin treatment, do not follow the fall of the blood sugar immediately.

Details of the action of insulin will be published elsewhere. It may be mentioned here that diabetes and hypoglycæmia can be more easily understood by considering that the essential task of insulin is rather to provide glycogen and to regulate its breakdown by the presence of the hormone itself and the level of glucose, than to lower the blood sugar. The latter may be considered the substrate of 'glucolysis proper' (Needham), the polysaccharide as the source of Embden ester which is an acceptor of further phosphate or oxygen. The loss of inorganic phosphate and the need of oxygen in insulin shock or the accumulation of compounds to be reduced (acidosis) in insulin deficiency, which is illustrated by the old saying of "fats burning in the fire of carbohydrate", may thus gain more biochemical substantiation.

Heterochromatin at the Distal Ends of the Chromosomes in *Triticum monococcum*

Kihara and Katayama[1] and Chizaki[2] studied meiosis in haploid *Triticum monococcum* ($n = 7$) and found that the chromosomes often become attached end-to-end, especially during diakinesis. It seemed very improbable that so many duplications or interchanges are responsible for this chromosome behaviour in the haploid *T. monococcum*. I suspected that this phenomenon is probably due to associations between heterochromatic regions of non-homologous chromosomes[3,4]. In studying this problem, I fixed root tips of *T. monococcum* in one part 1 per cent platinum chloride with one part commercial formalin and stained the preparations with Newton's gentian violet. In the chromosome plates of the preparations, stained somewhat more deeply than usual, I found that small portions of the distal ends of almost all chromosomes remained dark, while all the other parts became lighter (being very deeply stained). In the accompanying illustration are shown several chromosomes drawn separately from one and the same metaphase plate. Only the lighter and the darker regions are indicated.

This finding of differential staining suggests that heterochromatin might also be located at the distal regions, and that it is very probable that this heterochromatin is responsible for the end-to-end associations in the haploid *T. monococcum*. Associations between the heterochromatic (inert) regions of non-homologous chromosomes in *Drosophila* occur as a rule in the salivary glands. Our case suggests that this phenomenon is probably more general and is of great significance for the hereditable variations in plants and probably in animals. This problem is being discussed elsewhere.

Determination of Azeotropic Concentrations by the Twin Pycnometers Method

EXTREME precision and accuracy of the method of determining the density of liquid substances by means of twin silica pycnometers[1] opens up the way to precise determination of azeotropic concentrations. The new method is based upon investigating the relation between the density of a mixture of two components and its concentration. For this purpose, several mixtures covering either the whole scale of concentrations or the region about the expected concentration of the azeotrope under investigation, are prepared, and their densities are measured. Then an azeotropic mixture of the same components is distilled with an efficient column, its density is determined and the azeotropic concentration is read directly on the diagram, density/concentration.

The accuracy of this method depends upon the difference in density of the two components, but when dealing with organic liquids it is of the order of a few hundredths of one per cent or better. The certainty and the accuracy of this method are based also on working with high-purity substances and azeotropic mixtures as well as on the precise density determination. The easy means for measuring density of organic liquids within a few parts per million, which is secured by the use of the twin silica pycnometers method, and on the other hand the sensitive method of the control of purity of the liquids by the aid of Swietosławski's[2] differential ebulliometer, makes this method of determining the azeotropic concentrations superior in accuracy to other methods formerly used.

Actual examples will soon be published elsewhere.

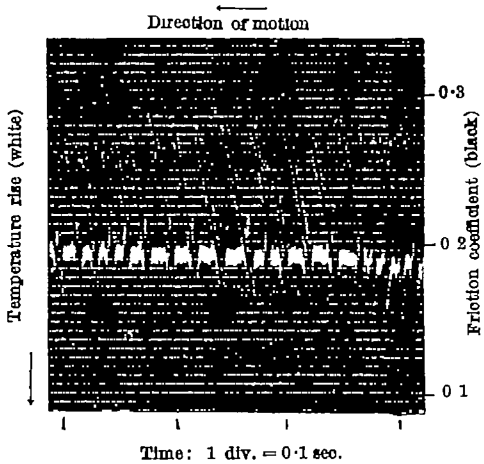
Nature of Sliding and the Analysis of Friction

MOST methods of measuring kinetic friction merely record the *average* force necessary to maintain sliding. On theoretical grounds, and from the results of some earlier more primitive experiments, it was considered probable that the frictional force between sliding metals might not be constant. An apparatus was constructed which was capable of recording any fluctuations in the frictional force if they occurred. The lower surface was driven at a slow uniform rate, and the top surface, which rested on it, was attached to a high-frequency device for measuring the friction.

Experiments with this apparatus show that the frictional force is indeed not constant, but is undergoing most violent fluctuations. Sliding is not continuous; the motion proceeds in jerks. The top surface 'sticks' to the bottom one and moves with it until, as a result of the gradually increasing pull, there is a sudden and very rapid 'slip'. The process is then repeated indefinitely. Experiments with a number of different metals and other solid surfaces prepared and polished in various ways show that this phenomenon is a general one. It is not due to surface scratches or irregularities. Even if the surfaces are lubricated with a mineral oil or other lubricants the behaviour may be essentially the same. Sliding proceeds by a process of 'stick and slip'. Certain long-chain fatty acids will, however, cause continuous sliding.



It is possible, by using two different metals as a thermocouple, to measure the surface temperature reached by the sliding metals. Earlier work has shown that this local surface temperature may be very high indeed[1]. A simultaneous analysis of the friction and the surface temperature is given in the accompanying photograph. In this case the top surface was of constantan and the lower surface was of steel. The metals were lubricated with medicinal paraffin and the lower surface was driven at a slow uniform rate of 0·3 cm. per sec.

The black trace measures the frictional force between the surfaces and it will be seen that large fluctuations are occurring in it. The slope of the darker portion of this trace corresponds to the speed of movement of the lower surface so that no relative motion is occurring; the surfaces are sticking together. Then suddenly a very rapid 'slip' occurs. This 'slip' is so rapid that it cannot be followed with accuracy. The surfaces again 'stick' and the process is then repeated.

The white trace measures the surface temperature. It will be seen that the surface temperature remains sensibly constant during the 'stick'; but, at the instant that 'slip' occurs, there is a sudden very rapid rise and fall of the temperature. The whole temperature 'flash' may be over in less than one thousandth of a second. (The temperature rise is shown by the downward movement of the white trace. It appears only faintly on the photograph. The more obvious upward kick beyond the zero is instrumental and may be ignored.)

The fact that an intermittent clutching and breaking away of the surfaces takes place during sliding and that the friction and the surface temperature are fluctuating violently has an important bearing on the theory of friction and lubrication.

Possible Role of Urea in Formation of Cancerous Growths

The interesting method of treatment of osteomyelitis developed in recent years in the United States is well known. First 'surgical maggots' were used. Then it was found that the beneficial effect was due to the presence of allantoin in the natural excretions of the maggots, so that the use of the latter could be eliminated. Later research showed that the chemically related (and much cheaper) substance urea could be substituted for allantoin in the treatment of osteomyelitis.

Apparently, one effect of urea is to cause rapid multiplication of cells. Is it possible that urea may be a factor in the formation of cancerous growths in the human body, either owing to an excess of urea in the blood stream or to certain organs being made more susceptible to the action of urea by minor lesions?

Points from Foregoing Letters

Further evidence for the existence of particles with mass between that of the electron and that of the proton is given by Dr. E. J. Williams and E. Pickup. They describe four curved tracks obtained in a Wilson chamber using magnetic fields of 1,000 and 2,200 gauss. The tracks indicate that the mass of the new particle is nearly 200 times the electronic mass.

Photographs showing the sedimentation (in an ultra-centrifuge) of cucumber viruses 3 and 4, are submitted by Dr. W. C. Price and Dr. R. W. G. Wyckoff. Two highly infectious heavy components were almost completely separated by a field of 40,000 times gravity acting for half an hour. They have the same sedimentation rate as the tobacco virus, but are 'insoluble' in water. The presence of a homogeneous high molecular weight substance, other than the virus, was also demonstrated in the cucumber plant, and the authors consider that the study of such non-infectious heavy proteins may throw light on the origin of the virus.

Graphs showing the cosmic ray intensity and the magnetic horizontal force between January 16 and 26, when magnetic storms and brilliant auroral displays occurred, are given by Prof. V. F. Hess, R. Steinmaurer and A. Demmelmair. The graphs show a close parallelism (the variation of the ionization due to cosmic rays being 0·82 mJ for a change in the magnetic horizontal component of 1γ or 0·00001 gauss). The effect, the authors state, may be explained by Chapman's hypothesis of corpuscular ring currents, fed by solar eruptions, encircling the earth at a distance of a few earth radii.

A curve showing the canalization effect of an iron tube 70 mm. diameter and 8 mm. thick upon gamma rays from radium (B + C) filtered by 0·5 mm. of platinum, is submitted by Prof. F. L. Hopwood and Dr. T. E. Banks.

Dr. L. Landau calculates that the laminæ of the intermediate state of supraconductors have to become thinner towards the surface, producing a kind of mixed phase very close to the surface.

A curve illustrating the changes in the resistance to extension of wool fibres in buffer solutions of varying *p*H, with and without previous cyanamide treatment, is given by Dr. J. B. Speakman, B. Nilssen and C. S. Whewell. The authors state that the results support the salt-linkage hypothesis of the structure of wool.

Prof. J. Runnström and E. Sperber submit graphs showing the consumption of glucose by baker's yeast —with and without the addition of cystein—through respiration, fermentation and synthesis of higher carbohydrates. Baker's yeast which has been kept in a dry state resembles to some extent that to which cystein has been added.

D. M. Reid writes that in a collection of the fresh-water shrimp *Gammarus* from Ireland, he has found that all the specimens belong to the species *G. duebeni* and not to *G. pulex*, which is the usual species in the fresh waters of Europe.

According to H. Lehmann, the formation of Embden ester in extract of muscle and dried yeast from glycogen and inorganic phosphate is considerably retarded by minute amounts of insulin.

Prof. D. Kostoff finds that the distal ends of the chromosomes in *Triticum monococcum* stain more deeply when fixed with platinum chloride and formalin and treated with Newton's gentian violet. He suggests that the presence of heterochromatin is responsible for the end-to-end association of the chromosomes.

A detailed analysis of the kinetic friction between unlubricated metals made by Dr. F. P. Bowden and L. Leben shows that the frictional force is not constant but is fluctuating violently. Sliding is not a continuous process; motion proceeds by a process of 'stick and slip'. When 'slip' occurs the surface temperature rises and falls again very rapidly. Even if the metals are lubricated with mineral oils the behaviour is essentially the same.

Research Items

Greek Wolf Lore

A dissertation by Dr. Richard Preston Eckels on "Greek Wolf Lore" (Philadelphia: University of Pennsylvania, 1937. Pp. 88) discusses the place of the wolf both in popular belief and as the object of a cult in ancient Greece, and concludes generally that the evidence is unfavourable both to the view of A. B. Cook that in connexion with the cult of Apollo it is a manifestation of a 'light' cult, and the view that it points to totemism in Greece. The author touches incidentally on the Romulus and Remus legend, which he concludes is not of Greek origin, and its modern parallels of children reputed to have been suckled by wolves and other wild animals. In coping with wild animals, primitive man has two choices only, extermination and domestication. The wolf problem could be solved partially only by domestication, and the wolf, with an effective range of about thirty miles, was in Europe a constant danger to the shepherd. In European folk-lore, therefore, it holds an arbitrary position as the wild animal most widely feared and the embodiment of all that is most malignant and terrible in the natural world—an unconscious abtraction that may be called the Baleful Beast, a mirror of the darker side of human imagination. A number of folk-lore beliefs were current in ancient Greece, such as that the wolf had one cervical vertebra only, that he was an eater of earth and that he was stupefied by squills, while men became mute when they met the wolf's eye, but music could put him to flight. An examination of Greek wer-wolf belief in relation to the beliefs in other wer-animals, as found widely distributed, reduces the importance of the wolf as a specific vehicle of the superstition. The belief is seen to be a manifestation of the Baleful Beast, one of a number of animals which appear in 'shape-shifting'. The more difficult problem is the place of the wolf in certain cults—Zeus Λύκαιος, Apollo Λύκειος, and the belief that Leto, the mother of Apollo, was a wolf. The connexion of Zeus with the wolf and cannibalism in Arcadia seems a piece of folk-etymology to explain the epithet, while that with Apollo is probably derivative from an original function in popular belief of the protection of the flocks from harmful beasts.

A Giant Fairy Shrimp

Mr. James E. Lynch describes an enormous new species of fairy shrimp, discovered in 1935 by Mr. J. F. Clark of Washington State College from the vicinity of Coulee City, Washington, and later found in numbers by the author in temporary alkali ponds in the Upper Grand Coulee, 19 miles north of Coulee City, Grant County (*Proc. United States Nat. Mus.*, 84, No. 3025; 1937). This is the fourteenth species of *Branchinecta* to be described and the fifth reported from North America. In *Branchinecta gigas* the male measures 63 (61–70) mm. in length and the female 86 (69–97) mm. The only other species of the genus approaching it in size is *Branchinecta ferox* from Eastern Europe and Asia Minor, the female of which may reach 70 mm. *B. gigas* differs from all other species of the genus in its large size and in having the antennæ in the female as long as those of the male. It is interesting to find that its food is a *Diaptomus*, the intestine of fresh specimens being bright red from the remains of this crustacean which it has eaten.

West North American Mollusca

A. Myra Keen has expended a great deal of labour in making the check list of west North American Mollusca ("An Abridged Check List and Bibliography of West North American Marine Mollusca". 1937. Stanford University Press). An enormous amount of matter is compressed into this small volume, which is very useful to all conchological workers, especially on the statistical side. Ranges of all species are given. The method employed for using the list to its full advantage is simple, and a large amount of information can be obtained, including literature during the past thirty years besides references to other works of general importance. The maps and diagrams are on the small side and require much enlargement in order to read them, but the whole is comprehensive and a valuable addition to any molluscan library. The book has been reproduced from typewritten sheets.

A Leaf-rolling Weevil

Gum leaves rolled into cylinders and known as 'ant-letters' have been attributed in parts of Australia to the activities of ants of the bullant tribe (Myrmecii). But since the structure of the mouth parts of these ants makes leaf-cutting impossible, John McAreavy has investigated the matter (*Victorian Naturalist*, 54, 123; 1938) and finds that the cutting and rolling of the small gum leaves and the regular scratches made upon the surfaces of the leaves are due to a weevil. The species concerned, *Euops falcata*, sub-family Attelabinæ, is common in Victoria and New South Wales. It works upon young gum trees or on suckers from old stumps, because on these the leaves are tender and easy to roll. The cutting is carried out by the female, and as soon as a leaf section is cut, the upper and sometimes the under surface also are marked with small scratches by the tips of the mandibles. The male takes no part in the operation, but remains close at hand upon the leaf, and at this stage mating takes place. Thereafter the female, after making a couple of deep cuts, which enable her to begin the rolling of the leaf, lays one yellow egg, and then proceeds to roll the rest of the leaf strip tightly with her feet. The cylinder is finally sealed by sticky sap squeezed from the cut surfaces by the rostrum of the beetle, and the author surmises that the scratches made upon the leaf-surface encourage the exudation of sap sufficient to hold the surfaces of the cylinder together as the rolling process is carried out. The beetles prefer for the formation of this egg-case the leaves of *Eucalyptus macrorrhyncha*, the red stringybark tree.

Incompatibility between Stock and Scion

INCOMPATIBILITY between stock and scion occurs in a number of fruit tree species and may be due to diverse causes. Dr. W. T. Chang, working at the East Malling Research Station, has investigated the problem in the case of pears, plums, cherries and peaches (*J. Pom. and Hort. Sci.*, 15, 4, 267; 1938). The symptoms of incompatibility were generally a low percentage take of grafts or buds, premature autumn leaf coloration and flower bud formation, early defoliation, and dying back of young shoots. Defoliation was basipetal in incompatible combinations and acropetal in compatible ones. The graft union was invariably weak mechanically in incompatible combinations due to discontinuity of bark or wood fibres or both, this being associated with slow diffusion of dyes across the union, resistance to flow of water under pressure, and a heavy deposit of starch above the union in November. It is concluded that mechanical weakness and obstruction at the union are the immediate causes of shoot and root decline in incompatible combinations, whilst differences in the periodicity of cambial activity and wide divergences between the growth periods of stock and scion are important contributory causes.

Soil Conditions and the 'Take-all' Fungus

MR. S. D. GARRETT has investigated the effects of soil reaction and aeration upon growth of *Ophiobolus graminis*, the fungus which causes 'take-all' disease of wheat. A recent paper (*Ann. App. Biol.*, 24, No. 4, 747–751, Nov. 1937) describes experiments upon the forced aeration of soil in relation to the incidence of the fungus. Such treatment was found to permit considerable activity of the organism in soils which were normally too acid for its good growth. Even in alkaline soils, aeration brought a marked increase in mycelial extension. Mr. Garrett has also evolved a method of clearing and staining fungus-infected rootlets (*Ann. Bot.* (New series), 1, No. 3, 563, July 1937). A solution of 0·04 per cent brom-thymol blue in 4 per cent sodium hydroxide is allowed to act upon the roots for a period of 5 minutes or more. The effect is a combination of clearing and maceration, whilst the brom-thymol blue stains fungal hyphæ to a deeper colour than any non-meristematic tissues of the host.

Age of the Slieve Gullion Gabbros

THE apparently ambiguous evidence bearing on the age of the Slieve Gullion gabbros has now been satisfactorily cleared up by Doris L. Reynolds (*Proc. Geol. Assoc.*, 247–275; 1937). The gabbro intrusions of Camlough Mt. and near Flurrybridge are shown to contact-alter the Caledonian Newry granodiorite in such a way as to cause the development of micropegmatite around each quartz group. As shown by alkali determinations, the alteration is a metasomatic change, potash having been introduced into, and soda driven out from, the granodiorite. The Slieve Gullion gabbro is found to be associated with a similar micropegmatite-bearing granodiorite and adamellite, and to enclose a block of the micropegmatitic granodiorite. Micropegmatitic veins extend from the zone of altered acid rock into the gabbro, both on Slieve Gullion and near Flurrybridge, and provide evidence that the metasomatized rock eventually became magmatic (rheomorphic). The rocks which result from the metasomatism and rheomorphism of the Caledonian granodiorite are shown to have petrological peculiarities in common with the Tertiary granophyre of Slieve Gullion. It is suggested that the Tertiary granophyre is the final product of metasomatism or rheomorphism of the Caledonian granodiorite. If this is so, it follows, since the change is correlatable with the gabbro contacts, that the gabbros are all (like that of Camlough Mt.) of Tertiary age. This is consistent with Egan's findings, that the gabbro and granophyre of Slieve Gullion mutually intrude one another. Richey's more recent conclusions, that the gabbros of Slieve Gullion and Flurrybridge are Caledonian, are shown to be founded on invalid evidence.

Distribution of Deep-Focus Earthquakes

MESSRS. B. Gutenberg and C. F. Richter, to whose work in connexion with deep-focus earthquakes we owe so much, have recently added an important memoir on the depth and geographical distribution of these earthquakes (*Bull. Geol. Soc. America*, 49, 249–288; 1937). They give a catalogue including all important deep-focus earthquakes from January 1, 1918, until March 31, 1932 (taken chiefly from the "International Seismological Summary"), as well as 12 earthquakes from 1905 until 1917, and 47 others from April 1932 until June 8, 1937, the total number being 255. The authors distinguish three classes of earthquakes, namely, normal earthquakes with focal depths up to 60 km., intermediate earthquakes with depths from 70 km. to 250 km., and deep earthquakes with depths from 350 km. to 730 km. It is a remarkable and well-established fact that no earthquake has been found with a focal depth much in excess of 700 km., a fact the more striking since some of the deepest earthquakes are among the greatest recorded. The distribution of earthquakes with very deep foci shows no direct relationship with the surface geology, though the epicentres occur in zones that are usually parallel to the larger structures. They are confined to zones bordering the Pacific Ocean, at some distance inland from the regions in which normal or intermediate earthquakes occur. The authors believe that the data already collected show that deep-focus earthquakes, like normal earthquakes, originate in a shearing or faulting movement, that takes place in the same direction over large areas and persists over long intervals of time.

Industrial Luminescence Research

IN the case of several manufactured products, luminescence can be employed to detect abnormalities. In *Philips' Technical Review* of January, A. Van Wijk describes a simple practical method of doing this by means of an 80-watt quartz-mercury lamp, the visible light being absorbed by a suitable filter. The filter is made of glass 'blackened' with nickel oxide and an extra addition to the molten glass cuts out the rays which cause conjunctivitis. In the Philips apparatus the lamp is surrounded by an outer bulb of the filter glass and the total useful radiation of the lamp is made available. The author suggests possible uses for these luminescent lamps. For example, it is known that the age of hens' eggs can be ascertained at a glance by means of the fluorescence of the shell. A fresh egg fluoresces red, and an old egg blue. It is stated that luminescence analysis is the best method for checking large numbers of eggs, in an egg market, where whole racks can be inspected at once. If hard water which contains lime is used in a laundry, spots of insoluble calcium soap appear in the material. When these spots are new they are invisible under normal lighting conditions. But under the luminescence lamp they glow with a bluish brightness. Instead of using disfiguring numbers or other marks on linen the laundry stamps the incoming goods with a number in invisible ink which luminesces strongly. The ink is 'fast' to washing so that after being washed the goods can be sorted in the usual way by luminiscent light. Luminescence analysis is useful in the following industries: textile, paper, paint, rubber and food. In addition, there is room for application in goods inspection, and for detecting all kinds of falsifications—cheques, postage stamps, banknotes, paintings, etc.

Progress in Power Rectifiers

DR. W. G. Thompson's paper on recent progress in power rectifiers and their applications, read on March 17 before the Institution of Electrical Engineers, gives a general survey of the present stage of their development. The introduction of the arc rectifier into power engineering may be considered to mark the beginning of a new stage in electrical development. The engineer has not only to extend the scope of his technical knowledge so as to include a field of electron phenomena, hitherto regarded as the physicist's domain, but he has also to adapt in engineering practice much of the vacuum technique of the physical laboratory. During the last twenty years the steady progress of rectifier installations shows how effectively the new knowledge has been applied. Some of the outstanding advantages of the rectifier arc, used for converting alternating into direct current, are its static nature, robust construction, high efficiency and low cost. The demand for this type of apparatus is steady and progressive, and shows no immediate sign of diminution. More than four million kilowatts of rectifier plant is in operation throughout the world. There is now little competition between this plant and rotating machinery; the competition is now between different types and makes of rectifier. With one or two exceptions, recent progress in practice has been by way of improvement and simplification of existing types rather than by new innovations. At the present time power rectifiers are divided into two main groups: (1) vacuum, or more strictly low-pressure vapour apparatus and (2) non-vacuum types. Of the equipment installed the vacuum type is much the larger, but active experimental work is being carried out on alternative forms of rectifier. The power rectifier has a widespread application and there are no signs of its limits of usefulness being approached. Typical examples of rectifier traction work associated with British industry are the London Transport Board's system and the electrification of the Southern Railway, the South African Railways and the Polish State Railways.

The Aurora

THE meeting of the British Astronomical Association held on February 23 was devoted almost entirely to a discussion of the auroras of January 25. Prof. S. Chapman discussed auroras in general, and a considerable number of the members contributed notes and papers on the subject or took part in the discussion at the close of Prof. Chapman's address, which has recently been published (*J. Brit. Astro. Assoc.*, 48, 5, March 1938). Prof. Chapman showed on the screen the iso-auroral lines—most frequent along the auroral zone which was more or less circular, centred at the magnetic axis pole. The usual height of auroras is about 60 miles for the bottom of the streamers, though on rare occasions heights of 40 miles have been recorded. An aurora might extend 300 miles or more upwards. The association between auroras and sunspots is rather nebulous, though there is a definite increase in auroral activity at the times of sunspot activity, but good statistics are difficult because suitable conditions are essential for the observation of auroras. Particles ejected from the sun with parabolic or greater velocity would, if they came within the region of our planet, be guided along the magnetic lines of force and diverted to polar regions, assuming that they were electrified. The light of auroras is due to excited atoms returning to the normal state or to electrons recombining with ions, ionization and breaking up of molecules into atoms being due to collisions between the solar particles and our atmosphere. For this reason, the spectrum of the aurora gives us information, not about the particles, but about the constituents of the upper atmosphere; and this was shown to contain neutral molecular nitrogen, ionized molecular nitrogen, and atomic oxygen. Discontinuities in auroral light, large gaps of clear sky appearing between active regions, may find an explanation on the assumption that exciting agents are absent from these zones.

A Comparison Image Micrometer

MESSRS. C. R. Davidson and L. S. T. Symms have recently published a paper with the above title (*Mon. Not. Roy. Astro. Soc.*, 98, 3; Jan. 1938), in which they describe the results obtained with a comparison image micrometer applied to the 28-inch refractor at Greenwich. Mr. F. J. Hargreaves formerly described a method for improving the measurement of double stars (*Mon. Not. Roy. Astro. Soc.*, 92, 72; 1931). This consisted in producing in the field of the telescope an artificial double star which could be varied in distance, position-angle and brightness, so that it matched the real double star. He made a micrometer on this principle with which he obtained excellent results, and it was sent to Greenwich to be applied to the 28-inch refractor. A Wollaston prism was utilized to produce the double star, crossed nicols controlling the relative brightness of the components, and the paper describes fully the use of these additions to the original micrometer of Mr. Hargreaves. Very remarkable results have been obtained by the apparatus, the advantages of which are most apparent in the case of close pairs. Where it has been impossible to measure these with the filar micrometer owing to the overlapping of disks of diffusion, with the comparison image micrometer glimpses of the nuclei are of sufficiently long duration to observe whether the real and artificial images match. The authors are of opinion that the claim of great accuracy made by Mr. Hargreaves is fully justified, and a comparison between his results obtained with the original micrometer mounted on his 12-inch reflector and those obtained with the Greenwich instrument shows a remarkably close agreement.

Geology in Great Britain

Geological Survey Publications

REPORT FOR 1935

PART 1 of the "Summary of Progress of the Geological Survey of Great Britain" for 1935[1] contains the usual annual reports of the Geological Survey Board and of the Director. Besides giving particulars of the routine work carried out during the year under review, an account is given of the opening of the new museum and offices at South Kensington and of the centenary celebrations in July 1935 (see NATURE, 136, 75; 1935). A more detailed record of these important proceedings appears in the memorial volume which has since appeared from the pen of Sir John Flett on "The First Hundred Years of the Geological Survey of Great Britain". Sir John Flett retired from the position of Director in September 1935, and was succeeded by Dr. Bernard Smith, whose term of office was, alas, tragically shortened by his untimely death in August 1936 (see NATURE, 138, 354; 1936). The Survey suffered another serious loss by the sudden death in May 1935 of Dr. H. H. Thomas, who had served as petrographer since 1911. The vacancy thus caused was filled by the appointment of Dr. J. Phemister.

The Director's report contains an interesting review of the progress which has been made during the years of recovery since the War. More than a thousand maps were issued in the period 1920–35 and nearly two hundred memoirs were published. During 1935 itself forty-three maps were issued, while a further fifty-one were in the press at the end of the year; thirteen memoirs were also published, all of which have already been noticed in our columns (NATURE, 138, 373 and 389; 1936). It is announced that a geological map of England and Wales on the 1/M scale is in preparation, and that a similar map of Scotland on the scale of 10 miles to one inch is being put in hand.

Part 2 of the "Summary of Progress"[2] contains a series of papers on subjects of special interest. R. G. S. Hudson and G. H. Mitchell contribute a valuable account of the Carboniferous geology of the Skipton Anticline, illustrated by a clear and particularly instructive geological map. The greater part of the Dinantian succession is exposed in the area, and the age of the two major earth movements which affected these beds is clearly demonstrated. J. E. Richey describes the areas of sedimentation of Lower Carboniferous age in the Midland Valley of Scotland, with special attention to rhythmic cycles and lateral variation. Washouts in the Haigh Moor Coal of West Yorkshire are discussed by W. Edwards. An account of the geology (mainly Rhætic and Liassic) of the district around Dunhampstead and Himbleton in Worcestershire is given by T. N. George. Some notes on Corallian rocks near Cambridge are contributed by E. E. L. Dixon. An assemblage of ammonites from the Ampthill clay is described by W. J. Arkell, and a new species of *Taxocrinus* from the Delabole Slates of Cornwall by J. Wright. J. E. Richey records and discusses the distribution of apatite in British Tertiary igneous rocks. It appears that apatite tends to be most plentiful in the intermediate rock types and that gravitative settling of early-formed crystals is not a factor that leads to enrichment. An apatite rock from the Ordovician volcanic vent of Bail Hill in Dumfriesshire has been studied by W. Q. Kennedy, who regards it as a pneumatolytically altered calcareous sediment, the alteration having been effected by volcanic gases at relatively low temperature.

MEMOIRS

The memoir describing the geology of the Rothbury-Ashington district in mid-Northumberland[3] is mainly devoted to the representatives of the Carboniferous system. Beds of the Cementstone Group occur in the north-west, and as the dip is mainly to the south-east there is a progressive rise in the sequence in this direction, until Coal Measure strata are encountered along the coastal belt. Much of the area is covered by a varying thickness of glacial drift, and only to the north-west does the form of the ground bear any clear relation to the underlying structure. The Fell Sandstone is responsible for the most prominent topographical features, particularly around Rothbury and the Simonside Hills. The Great Limestone gives rise to minor features, as also does the Whin Sill, locally. The Coal Measures of the coastal belt form the northernmost part of Northumberland and Durham coalfield. Whereas in Durham coking and gas coals are characteristic, here steam and bunker coals predominate. Considerable progress in the correlation of the seams has been made in the course of the recent survey. Important records of borings and pits are given in an appendix.

The Gosforth District[4] forms part of the iron-ore field of west Cumberland and lies between the western part of the Lake District and the Irish Sea. The eastern portion is hilly and is occupied by the rocks of the Borrowdale Volcanic Series, along with some parts of the Ennerdale Granophyre and the Eskdale Granite. The Carboniferous is almost entirely concealed beneath the formations of the New Red Sandstone which form the lower ground to the west. The glacial history of the district is chiefly concerned with the waxing and waning phases of two episodes: the Main Glaciation and the Scottish Readvance Glaciation. In an interesting chapter on the structure the effects of Ordovician, Caledonian, Hercynian and post-Triassic movements are clearly distinguished. It is shown that the stock-like Ennerdale intrusion is later than the Caledonian folding, but possibly earlier than the thrusting and faulting. A similar position in time is probably to be assigned to the Eskdale Granite. The chapter on the igneous intrusions suggests many problems in petrogenesis that still await solution. The iron ores of the Carboniferous form a concealed extension of the exposed area to the north; they have already been described in an earlier memoir (1924) on the "Hæmatites of West Cumberland, Lancashire and Lake District".

The memoir on the Sanquhar Coalfield[5] is mainly devoted to a detailed description of the Carboniferous sediments of the Sanquhar and Thornhill districts in Dumfriesshire, but it also includes an account of the Permian rocks and of the Glacial and Recent deposits. Both districts are situated along the upper valley of the Nith, a river which flows south-eastwards across the southern uplands to Dumfries and the Solway. The Carboniferous strata are especially noteworthy for the number of exposures of fossiliferous horizons. The majority of the 'mussel' zones which have been established in England have been recognized at Sanquhar, and their vertical range can be fixed within relatively narrow limits. Accordingly, means are now available for comparing in a broad way the Coal Measure sequence of Sanquhar with that of Ayrshire on one hand and with the English successions on the other. The palæontology of the Upper Carboniferous is dealt with in appropriate detail, with excellent illustrations. The Permian volcanic rocks of Thornhill and Sanquhar belong to an assemblage that extends to the north-west at least as far as Ardrossan. Around Thornhill the Permian lavas are succeeded by brick-red sandstones made up largely of wind-rounded grains of quartz. These desert deposits have been correlated with the Penrith Sandstone of the Carlisle district.

Descriptive Handbooks

Eleven of the descriptive handbooks issued under the general title of "British Regional Geology" have already been noticed (Nature, 138, 389–391; 1936). Five more of these invaluable summaries of local geology have now been issued. To complete the series only two more have still to come. All the handbooks are beautifully illustrated with maps, diagrams and plates; they are sold at the remarkably attractive price of 1*s*. 6*d*. each.

"The Hampshire Basin and Adjoining Areas"[6] embraces the whole of Dorset, the greater part of Wiltshire and Hampshire, and the Isle of Wight. Here are exposed all the formations in the Jurassic, Cretaceous, Eocene and Oligocene systems, together with a variety of superficial deposits. Attractive scenery and many famous holiday resorts have made the area generally familiar, while the profusion of fossils in many of the strata have made the region a classic one in the history of palæontology. Structurally, this part of England has been folded by earth-movements—the outer ripples of the Alpine storm—which reached their maximum intensity during the Miocene. The diagrams, maps and other illustrations add effectively to a particularly interesting and well-written handbook.

"East Anglia and Adjoining Areas"[7] extends from the Wash to the Thames Valley District. Jurassic formations crop out in the west and Pliocene in the east, along the coast, while between these the Cretaceous occupies a broad stretch of country. The Crag (Pliocene) deposits of East Anglia, with their abundant and well-preserved shells and remains of other organisms, have attracted many famous geologists. In particular, the Cromer Forest-Bed is celebrated for its fossil trees and plants and vertebrate remains. East Anglia is also of special interest to the archæologist because of the many discoveries relating to the history of early man that have been made within the area. Here also occurs the most complete succession of glacial deposits to be found in England. Geologists and workers in related branches of science will appreciate the clear summaries that are given of these and many other topics of abiding interest. In future editions of the Hampshire and East Anglia handbooks a selected bibliography of publications additional to those of the Survey would be welcome.

"The Central England District"[8], though a somewhat arbitrarily defined area, stretches from East Anglia across the central plain to North Wales and the Welsh Borderlands and is of great and varied interest since its exposed rocks embrace all the geological systems from the Pre-Cambrian to the Jurassic with the exception of the Ordovician. The strata contain economically important deposits of coal, fire-clay, gypsum, salt and iron ore and, as a consequence, highly industrialized areas, comprising the Potteries and the Black Country and including Birmingham, Coventry and Stoke-upon-Trent, have developed. The southern part is mainly of a pastoral character, broken here and there by recent exploitation of iron ores. Apart from the Survey work, many fundamental contributions to Midland geology were made by Charles Lapworth, particularly with regard to the Pre-Cambrian and Cambrian rocks. Adequate recognition is given to his work and that of many well-known geologists who have followed his inspiring lead.

"The Midland Valley of Scotland"[9], measuring about 120 miles in length and 50 miles in breadth, is an ancient rift-valley bounded on the north-west by the great Highland Boundary fault from Stonehaven to the Firth of Clyde and on the south-east by the Southern Upland fault from Dunbar to Girvan. The principal formations are of Old Red Sandstone and Carboniferous age. In both systems there occur great thicknesses of contemporaneous lavas and tuffs and many intrusions in the form of vents, plugs, sills and dykes. Plateaux and ridges of volcanic rocks and smaller eminences and crags marking intrusions rise from the softer sediments and give the region its characteristically varied scenery. Petrologically the area is of unrivalled interest, and the handbook is especially noteworthy for the remarkably fine summaries that are given of the various superimposed petrological provinces. The excellent maps and correlation tables also deserve special mention. The handbook is, indeed, one that will be found invaluable by students and teachers alike, as well as by the interested amateur.

"Scotland: The Northern Highlands"[10] is the region that lies west of the Great Glen and its seaward continuations, the Moray Firth and the Firth of Larne. It includes the Inner and Outer Hebrides, but the Orkneys and Shetlands are excluded. A small part of the mainland and much of the Inner Hebrides are composed of Tertiary igneous rocks to which a special handbook has already been devoted (Nature, 138, 391; 1936). Otherwise, Scotland beyond the Great Glen consists mainly of Archæan, Torridonian and Palæozoic rocks, on which rest fragments of Mesozoic strata. The area has won world-wide renown among geologists for its great Caledonian thrust-zone, extending for 120 miles from Skye, through the classic belt of Assynt to Whitten Head. Here it was, in 1883, that Lapworth solved 'the secret of the Highlands'. The handbook provides an admirable summary of many fascinating groups of rocks: the Lewisian Gneiss with its associated intrusions; the Moine series and its injection complexes; the Torridonian and Cambrian; the post-Cambrian intrusions of Loch Borrolan and Loch Ailsh; the Newer Igneous Rocks and Hybrids of Ach'uaine; and the later formations from Old Red Sandstone to Pleistocene. Many excellent maps are given, making the handbook a most attractive guide to a region which hitherto has not been dealt with as a whole.

CATALOGUE OF FOSSILS

The Catalogue[11] of type and figured specimens of fossils in the Geological Survey Gallery of the Royal Scottish Museum will be useful to palæontologists. Localities and references are given. It is noted that the Dunlop collection and the material of the Hugh Miller, Traquair and Neilson Collections in the Natural History Department are outside the scope of the catalogue.

Noise on the Road

THE Departmental Committee of the Ministry of Transport, which was appointed in August 1934 to consider the source and prevention of the noises from mechanically propelled vehicles on the road, has issued its fourth and final report*, this time on the subject of warning devices. The Committee, to the work of which we have previously referred, and of which Dr. G. W. C. Kaye has been chairman since shortly after its inception, arranged for experimental measurements to be made of the noise levels of some forty present-day warning devices, in relation to both the annoyance which they excite and their degree of effectiveness under representative road conditions. The measurements were carried out for the Committee by the National Physical Laboratory as heretofore.

The warning devices subjected to test included electric buzzer-operated horns, electric gongs, sirens, Klaxon horns, bulb horns and wind-driven horns. Measured 20 feet away, the figures for the overall loudness ranged from 82 to 113 phons at the front, and from 80 to 104 phons at the side of the warning device.

In the difficult task of assessing the degree of annoyance caused by different types of horns, more than 200 people, both old and young of both sexes, were invited to record their impressions of the various sounds, under the headings of agreeable, tolerable, objectionable, very objectionable, and unbearable. While the divergence in the opinions was perhaps even wider than might have been anticipated, nevertheless the observations, some 30,000 in number, plainly indicated the influence of increasing loudness on the scale of annoyance. There are other factors, of course; for example, the Committee conclude that horns emitting musical sounds marked by the absence of strong high-frequency components tend in general to be regarded as less annoying than harsh or non-musical high-pitched sounds of equal loudness. Furthermore, the circumstances, for example, the inconsiderate staccato or sustained operation of a horn by the user, can markedly influence the annoyance factor. But in general, if a single criterion of annoyance is looked for, which will lend itself to measurement and can be made the basis of regulations, then the loudness would seem to fill the bill sufficiently adequately in a large majority of cases.

On this basis, the Committee infers that from the point of view of residents, pedestrians and other quiet road users in relatively quiet streets, horns of loudness exceeding 95–100 phons at a distance of 20 feet are likely to cause a material degree of annoyance. In relation to such conditions, it is clear that many present-day motor-horns are excessively loud. From the point of view, however, of a driver subjected to the noise of his own vehicle and who is being followed by another vehicle desirous of overtaking, the tests show that horns of loudnesses of the order of 105 phons may be necessary in the case of vehicles of moderate noise-level, such as private cars and light commercial vehicles, while horns of so much as 110 phons or more may be required to attract the attention of drivers in the cabs of heavy noisy lorries. In such circumstances, horns with very distinctive characteristics are most readily noticeable.

A compromise to meet these diverse requirements had to be arrived at, and the Committee was led to recommend a loudness limit of 100 phons at 20 feet, as one which would result in material improvement as regards annoyance from horns to quiet users of the road, and which would be sufficient to meet the needs of the majority of drivers of vehicles. It points out that, as and when compliance is obtained with the recommendations concerning the level of motor-vehicle noise in their previous reports, the difficulty experienced by drivers of very noisy vehicles in hearing horns which are not extremely strident will be progressively reduced.

The Committee was given a difficult task, and now that its work has been brought to a successful conclusion, appreciation may be expressed of the way it has directed chief attention to the small and noisy section of road users, so that its recommendations, if brought into force, would not inconvenience the great majority who have consideration for the amenities of the road.

Anthropology as an Imperial Study*

THE process of incorporation of subject peoples into a great imperial organization, such as the British Empire, with duties, responsibilities and privileges, for which their previous experience has all inadequately prepared them, only too often has been so severe an ordeal that the novice has succumbed to the hardships involved, and instead of attaining a fuller life in a new society of peoples, has disappeared from among the nations of the earth.

Sometimes this disappearance has been the result of deliberate and calculated severity, as the Easter Islander at the hands of Peru, or the Tasmanians at those of the British. Far more often the fatalities of this ordeal have been the result of ignorance, of indifference or even of kindness misdirected with the best of intentions, as has happened in the Andaman Islands, where the Rev. Mr. Corbyn's policy of attempting to civilize the Andamanese has combined with other factors, such as the introduction of diseases from which the Islanders had not acquired immunity, to reduce the number of inhabitants from 5,000 in 1858 to 460 in 1931.

The causes of such decline have been variously estimated. A some-time lieutenant-governor of Papua is quoted as writing of "tribes who apparently must disappear before long, and when one considers their habits the only cause of surprise is that they should have come into existence at all". The habits specified seem to be child-marriage and "the probability of unnatural offences and other filthy customs", which do not afford convincing testimony of the causes of decline. Native customs, often repugnant to Europeans, such as head-hunting expeditions, are frequently the culminating point of a preparation lasting over years, which has provided interesting work in the building of canoes, etc., punctuated by rites and feasts relieving the monotony of life, and stimulating agriculture and pig-breeding. On the economic side again, the introduction of coin into the Naga Hills of Assam and its greatly increased circulation have led not only to much indebtedness, but also to the growth of a landless class. Loans formerly repaid in kind are now paid in cash, to obtain which something must be sold, generally the land, leading to a loss of independence. Great harm has been done by the complete failure to understand native systems of ownership and tenure of land.

In many parts of Asia and Africa, ownership has been communal. Under this system, destitution is impossible; for the tribe is responsible for all its members. It has happened repeatedly, however, that the chief has been treated as owner and not as trustee, as he really is. The deplorable results can be seen in the landless condition of a large proportion of the Indians of North America, or in conditions among the aboriginal tribes of India, especially in Chota, Nagpur and the Chittagong Hills, where the chief has been converted to Hinduism, and has alienated the land, which belonged to the village, and not to him as an individual. A similar misunderstanding of the tribal point of view is likely to arise in the case of many customs, and also in the administration of justice. Among the aboriginals of India the application of a system of law, which they do not understand, has more often than not resulted in ruining them economically and degrading them morally. Even the efforts of missionaries have succeeded in adding to the black man's burden by undermining the prestige of the natural leaders of the people, the pastor encroaching on the prerogative of the chief. When the chief, the medicine man, and other natural leaders become mere figure-heads, native culture no longer offers any objective worthy of effort or sacrifice, and the native lapses into an existence devoid of purpose or ambition, and, therefore, of contentment. A people who have thus lost interest in life succumb to any disease of body or mind and fail to reproduce their species in sufficient quantity to survive the chances of death.

Other causes might be cited, indicating the responsibility for decline—at any rate in part; but if we assume that decline had set in before the white man came, of what value is the culture he has to offer, if it cannot arrest, but only accentuates, the existing process of decay. We have no right to incorporate in our system peoples of other culture than ours if the ordeal of that incorporation be so severe as to destroy the peoples incorporated.

It is here that the study of anthropology comes in. The first necessity in dealing with a race of so-called 'primitive' culture, as Dr. A. C. Haddon pointed out so long ago as 1921, is an ability to adopt an attitude in which the observer divests himself entirely of his own outlook on life, and regards everything from the point of view of members of the other race, as they exist for themselves in their own scheme of life. If such a point of view is at all attainable, it is through a study of social anthropology that it can be obtained with least difficulty. For to the anthropologist all customs are natural, and even head-hunting and cannibalism are not revolting crimes, but reasonable and inevitable acts resulting from beliefs and ideas logically applied to circumstances and environment. A failure on the part of administrators and administered to recognize each other's point of view may well lead to rebellion or disturbance, but must certainly lead to apathy, depression and degeneracy on the part of the administered, whereupon, as W. H. R. Rivers pointed out, they languish and die.

The anthropologist can do a great deal towards solving these difficulties, if the various branches of that science act in collaboration. The dangers of apathy, depression, and decline is primarily the province of the social psychologist. If the result of the impact of Western civilization can be foreseen, any sudden upsetting change can be guarded against. Thus an outlet has been provided to take the place of head-hunting in New Guinea, where the substitution of a wild boar has averted the deleterious effects on the marriage rate, which threatened when head-hunting was abolished. Similarly, problems of interbreeding and the influence of changed conditions of life, owing to the introduction of new styles of dress or in buildings, call for investigation. For the anthropological economist, problems are raised by changes in the methods of production, and by such measures as the wholesale suppression of slavery, which latter on the Assam-Burmese frontier has thrown land out of cultivation. The introduction of mill-spun yarn or machine woven cloth may completely supersede indigenous manufacture, to the great detriment of certain sections of the community. Again, in Assam, the anthropologist will discover that the administration of previously independent tribes has had a deleterious effect. The old conditions of intermittent warfare, raids, and head-hunting involved competition and a hard life, the need for vigilance, resource and quick reactions. Personal efficiency was the primary standard, and wealth secondary. With the prevention of warfare and raiding, wealth comes to stand first and the whole tribe suffers by the change.

---

* Substance of the inaugural lecture of Dr. J. H. Hutton, William Wyse professor of social anthropology in the University of Cambridge, delivered on February 14.

The imposition of taxation is another important factor in change, necessitating the use of money, leading to detribalization and the acceptance of European values. Another difficulty is the belief in witchcraft, which cannot be ignored as a vain superstition, when the people themselves believe in it.

The obstacle in the way of anthropology's contribution to the solution of these and other problems has been in the past largely due to the absence of recognition of the practical value of this science. The end of the Great War, as Rivers prophesied, has brought the duty of meeting old responsibilities in new ways. The feeling is growing in Great Britain that dependencies inhabited by people of primitive culture are held in trust primarily for their inhabitants, and secondarily for the world in general. Those responsible for the administration of such areas have been slow to recognize the value of anthropology in meeting such responsibilities. The Colonial Office, it is true, has now recognized the value of a knowledge of anthropology, and probationers going out do not now go out without at least some knowledge of that science ; but politicians and men of affairs are apt to regard learning and theoretical knowledge with consistent distrust.

Forest Products Research

THE report of the Forest Products Research Board for the year 1936 with the report of the Director of Forest Products Research for the same year (H.M. Stationery Office, Dec. 1937) give evidence of the increasing interest being taken in timber research by industry.

The Board states that the period covered by the report has been of special importance to the Board as it includes a survey of the work and policy of the Forest Products Research Laboratory carried out on behalf of the Department of Scientific and Industrial Research by a Committee appointed for the purpose. It is of public interest to know that inspections of this nature are held periodically by the Department on the various activities under its control and the Board welcomed the opportunity thereby afforded to review the present position and to adjust future policy. Throughout the year, the Board was in close touch with the Reviewing Committee set up by the Department and the suggestions of the Committee were submitted to the Board for opinion at a meeting held at the Forest Products Laboratory at Princes Risborough in October. The Board's comments were afterwards laid before the Advisory Council for Scientific and Industrial Research.

During the year, more than 2,200 inquiries were dealt with at the Forest Products Research Laboratory—or twice the number dealt with five years ago, a fourth of these being from trade sources, asking for advice and assistance in practical problems connected with the seasoning and bending of wood.

As evidence of the varied nature of the work undertaken at the Laboratory, tests were carried out for British firms in the country on a number of species of foreign timbers, on the strength of a new fire-resisting wall board, on timbers for aircraft, for furniture and on a method of packing crushed bamboo and on the adhesion of plywood and glued joints generally. Another fourth of the inquiries, the majority from private individuals, related to the attacks on timber by beetles.

An interesting and perhaps unsuspected outcome, as the result of a large number of mechanical tests on selected hardwoods similar in weight, is the determined factor that tropical timbers are generally inferior in resistance to shock (toughness) to those grown in temperate regions. On the other hand, the tropical timbers are appreciably stronger in resistance to compression parallel to the grain. Both these strength properties are fairly closely related to specific gravity or weight per cubic foot and, therefore, indirectly to one another ; but statistical analysis shows that toughness and strength in compression parallel to the grain are inversely related. Search has been made, among the newer Empire timbers from tropical Africa and Asia recently appearing on the markets, for substitutes for ash and hickory but none of outstanding toughness have yet been discovered to replace these two well-known timbers.

The report deals with the investigation work carried out on shrinkage problems, box testing, insect and fungus researches, plywood products and test work in connexion with Empire timbers. Several species of the latter are mentioned. It would appear that in some of these cases the work of the Research Laboratory is in advance of the Colonies and their Forest Departments from which the timbers originate. It is of little practical utility to the trade to know that a timber is of value for a particular purpose when the commercially accessible amounts available in the forest are to a great extent unknown ; whilst working plans safeguarding the correct exploitation of the forests, as understood in India, have yet to be drawn up for the greater part of the areas under the Colonial Forest Services.

Science News a Century Ago

The Botanical Society

AT a meeting of the Botanical Society on April 20, 1838, a paper by A. Wallis was read on the genus *Myosotis*. The *Myosotis arvensis*, he said, is most usually found in cornfields, or other highly cultivated land, where it sometimes reaches a considerable height. The *Myosotis sylvatica* is mostly found in shady places, where it assumes a stouter form than *M. arvensis*; the bristles of the leaves are shorter and the leaves will generally be found longer than those of *M. arvensis*. There is another distinction also, for which neither soil nor locality would account; it is that the calyx of *M. sylvatica* is more deeply cleft than *M. arvensis*, and the tube of the corolla is longer in the former than in the latter, but he was inclined to doubt whether these were sufficient to justify a specific distinction. Admitting that a difference of soil operates so powerfully in producing such varied and perhaps permanent distinctions of character, it would become a subject worthy of attention how this peculiar operation takes place, and whether by close observation of soil and locality, we may not be able to establish geological laws.

Exploration of the Coast of North America

THE *Athenæum* of April 21, 1838, under the heading "Arctic Discovery Expedition", gave an account of the exploration of the northern coast of North America in 1837–38 by Peter Warren Dease and Thomas Simpson (1808–40), two of the staff of the Hudson's Bay Company. The expedition had been organized by Sir George Simpson (1792–1860), the administrator of the company. "Just half a century had elapsed since Alexander Mackenzie, in 1789, first descended the great river which so justly bears his name and reached the waters of the Polar Sea. Thirty-seven years later, in 1826, Franklin and Back followed Mackenzie's course to the mouth of the same river and coasted 370 miles to the westward tracing the northern shore of America till within 160 miles of Port Barrow, which had been reached only four days after Franklin was obliged to return. The intermediate portion has remained a blank on our maps till the present week brought us the gratifying news of an expedition headed by Messrs. Dease and Simpson . . . having successfully traced the unexplored country between Point Barrow and Franklin's farthest; and thus a continuous line of 60 degrees in extent from Point Turnagain on the east to Behring's Strait on the west has been explored by British hardihood and perseverance." Point Barrow had been reached in 1826 by Elson during Beechey's expedition to the North Pacific in the *Blossom*. Dease and Simpson had spent the winter of 1836–37 at Fort Chipewayan on Lake Athabasca and on the opening of navigation had descended the Slave River and Mackenzie River and had reached the ocean by the most northerly mouth of the latter.

Harper and Joyce's Heating Stove

WHEN Dr. Neil Arnott's method of heating rooms was attracting attention, considerable interest was aroused by the exhibition at the Jerusalem Coffee House of a stove invented by Harper and Joyce designed to burn prepared charcoal which it was claimed gave out no smell and did not vitiate the atmosphere. It was the subject of a lecture by Prof. Everitt before a well-attended meeting of the Westminster Medical Society on April 21, 1838, and it was also described before the Paris Academy of Sciences by Gay Lussac. In his report, Gay Lussac said: "Much has been said of the wonderful nature of this process that with an expenditure of fifty or sixty centimes [5*d*. or 6*d*.] in properly prepared charcoal, a vast apartment may be maintained at an agreeable temperature for twenty-four hours, and moreover that the carbonic acid produced by the combustion is not diffused in the apartment, being absorbed by the carbonate of soda with which the charcoal is impregnated, the danger of suffocation therefore no longer to be dreaded from this method of heating. This much boasted process has appeared to me to be deserving of my examination; and in making the results known, I believe I am doing a duty to the public and performing a duty incumbent on me. . . . The elegant apparatus in which the charcoal is burned, is a true brazier, diffusing all the products of combustion into the apartment where it is placed, and it is from these circumstances that the asserted economy rises. This economy cannot be disputed, but it should not be forgotten that it is gained at the expense of vitiating the air of the apartment."

Medical Biography

THE issue of the *Gentleman's Magazine* of April 1838 contains the following review of the first part of the "Medical Portrait Gallery" by Thomas Joseph Pettigrew which had recently appeared: "The author advances the claims of this work by stating the general deficiency of Medical Biography, and by remarking that the history of the Progress of Medicine cannot be more agreeably displayed than in a detail of the researches of the most celebrated professional men, who have successfully toiled in the pursuit of Science. That this range of view will be most comprehensive is shown by the subjects comprised in the first number: Esculapius (from an antique whole-length statue); Sir Henry Halford; and Albinus, a very learned German of the last century. Of the engravings it is sufficient to say that the style of their execution is guaranteed, from being executed under the now well-experienced superintendence of Messrs. Fisher, of Newgate Street. In the accompanying Memoirs Mr. Pettigrew has added to his already well-earned fame as a medical historian and antiquary.

Medieval Mummy

THE *Gentleman's Magazine* of April 1838 contains the following information: "Among the curiosities recently added to the Museum of the Royal Society of Northern Antiquities at Copenhagen there is one of a singular nature and of great historical interest. It is the mummy of a female, found in a peat bog near Haraldskioer in Jutland, completely sunk in the soft ground, and fastened to a stake by means of clamps and hooks. The fragments of clothing that remain on the mummy enable the skilful antiquaries of the north to calculate with tolerable certainty that it belongs to the last period of paganism, and M. Petersen has endeavoured in an able historical essay to prove that the mummy is the body of Gunhilda, Queen of Norway, whom King Harald Bloatend enticed by promises of marriage to come to Denmark in 965 where he put her to death by sinking her in a bog."

Societies and Academies

London

Royal Society (*Proc.*, A, 165, No. 920, 1–160).

J. E. Lennard-Jones and A. F. Devonshire: Critical phenomena in gases. (2) Vapour pressures and boiling points.

P. M. S. Blackett: The nature of the penetrating component of cosmic rays.

D. Porret and C. F. Goodeve: The continuous absorption spectra of alkyl iodides and alkyl bromides and their quantal interpretation.

C. Corin and G. B. B. M. Sutherland: The infra-red absorption spectrum of methylene chloride.

S. Tomotika: On the velocity and temperature distributions in the turbulent wake behind a heated body of revolution.

S. Tomotika: Application of the modified vorticity transport theory to the turbulent spreading of a jet of air.

L. F. G. Simmons and C. Salter: An experimental determination of the spectrum of turbulence.

C. A. Coulson and W. E. Duncanson: Comparison of wave-functions for HeH^{++} and HeH^{+}.

E. H. S. Burhop, R. D. Hill and A. A. Townsend: The production of gamma-rays by neutrons.

M. C. Johnson and A. F. Henson: Oscillography of adsorption phenomena. (3) Rates of deposition of oxygen upon tungsten.

Paris

Academy of Sciences, February 14 (*C.R.*, 206, 465–544).

Gaston Julia: The inversion of limited linear operators belonging to the third and fourth classes of Tœplitz.

Ernest Esclangon: The rotation of the galaxy.

Dimitri Riabouchinsky: Approximate equations of the three-dimensional movements of a perfect compressible fluid.

Stanislas Christian Zaremba: Kronecker's index.

Michel Ghermanescu: The exceptional combinations of integral functions.

Mlle. Alice Roth: The radial limits of integral functions.

Michel Scherer: An arrangement allowing the simultaneous measurement of reactions on two juxtaposed wings.

Léon Rebuffé: Two limit laws concerning the velocity of rebound and absorbed energy, in the case of the shock of a hard body on a soft metal.

Marcel Peschard: The spontaneous inflammation of hydrocarbons mixed with oxygen and its relations with the octane index.

Louis Goldstein: The theory of sprays of protons and of neutrons.

Georges Durand: The application of the mass-luminosity relation to the calculation of the parallaxes of double stars with eclipses.

Junior Gauzit: The presence of the first positive group of nitrogen in the spectrum of Finsler's comet (1937*f*).

Jean Roubaud-Valette: The expression of physical magnitudes as a function of new magnitudes belonging to a sub-space.

Albert Pérard: A method for the absolute determination of light wave-lengths as a function of the metric unit.

Paul Renaud and Georges Costeanu: The distribution in direction of steam issuing from a capillary.

Constantin Salceanu and Corneliu Istraty: Acoustic resonance spectra of liquids.

Jean Paul Cance: A new method of measuring the velocity of sound in liquids by ultra-sound capillary interference.

Pierre Vernotte: The division of the flux of heat in double-wall methods.

Jean Villey: Adiabatic compression with *remisage*.

Oleg Yadoff: The removal of electric charges by means of a high velocity jet of air.

Pierre Barchewitz: The complexity of the (CH=) bands of benzene derivatives. Discussion of the conclusions to be drawn from the study of the infra-red and Raman spectra of benzene and its derivatives. The senary symmetry of benzene is not in contradiction with a ternary symmetry in the distribution of the electric charges: on the contrary, it confirms it.

Charles F. Squire: The thermal variation of the Cotton-Moulton constant for the liquid aromatic hydrocarbons.

Maurice Henri Pirenne: The diffraction of the X-rays for silicochloroform. The geometrical structure of the molecule $SiHCl_3$. The valency angle is within two or three degrees of the angle of a regular tetrahedron, and in agreement with the view of G. Urbain the $SiCl_3$ group admits of a plane structure.

André Boullé: Calcium trimetaphosphate. Calcium trimetaphosphate has been prepared by the reaction of sodium chloride with silver trimetaphosphate. This salt has been characterized by its composition, behaviour on heating and X-ray spectrum.

Albert Portevin and André Leroy: Methods of estimation with microsamples, and applications to metallurgical studies. Details of methods of determining manganese, phosphorus and chromium in 1 mgm. samples of steel.

Henri Wahl: Methyl β_1-methoxy-β_2-naphthoylacetate.

Boris Owodenko, Henri Termier and Gaston Delépine: The presence of the Silurian and of the Devonian to the south of Naima (Oudja, Eastern Morocco).

Gonzague Dubar: The formation of folds at the Aalemian and Bajocian in the Haut-Atlas of Midelt.

Hubert Garrique and Henri Camichel: The aurora borealis of January 25, 1938, observed from the Pic du Midi.

Henri Marcelet: The presence of a C_{18} aldehyde-alcohol in olive pulp.

Raoul Lecoq and Roger Duffau: Cure of acute glucidic alimentary lack of equilibrium in the pigeon and its repercussion on muscular glucidic metabolism.

Serge Tchakhotine: Heredity and leucocytic proportion of the blood in mice.

Jean Jacques Pérez and Georges Sandor: The solubility optimum and isoionic point of the psuedoglobulins of horse serum.

Albert Berthelot and Mlle. Germaine Amoureux: The formation of 3-indolacetic acid in the action of *Bacterium tumefaciens* on tryptophane.

Mme. Marguerite Lwoff: Hæmatin and ascorbic acid: growth factors for the flagellate *Schizotrypanum cruzi*.

Th. E. de Jonge-Cohen : Doubling of the front teeth.

G. H. R. von Kœnigswald : A new *Pithecanthropus* skull. Description of the skull discovered on August 13, 1937, near Kampong Bapang in the Dutch East Indies.

Tokyo

Imperial Academy (*Proc.*, 14, No. 1, 1–26, January 1938).

Masao Sugawara : An invariant property of Siegel's modular function.

Mankiti Hasegawa and Yûita Tamura : The regular progressive changes of the magnetic field of diurnal variations of terrestrial magnetism. (2) It is concluded that the zonal variations are the principal part of the solar diurnal variations of terrestrial magnetism.

Waro Nakahara, Fumito Inukai and Saburo Ugami : Factor L (vitamin L) requirements for lactation in pregnant rats. It is concluded that factor L (vitamins L_1 and L_2) is necessary for establishing normal lactation, but once established the factor L requirement for the second lactation may become smaller.

Shinkichi Yoshimura : Limnology of two lakes on the oceanic island, Kita-Daitô-Zima. The two lakes, Aka-ike and Oo-ike, though they are in the interior basin of an island of coral limestone, are considered a type between eutrophic and dyotrophic.

Masuzo Uéno : Plankton of the lakes in Kita-Daitô-Zima.

Sanshi Imai : Third note on *Elaphomyces* and fungus-inhabiting *Cordyceps* in Japan. Three fungi, new to Japan, are described.

Mamori Ichikawa : Induction of gills in *Triturus pyrrhogaster*.

Haruo Kinosita : Chronaxy of individual fibres in nerve.

Vienna

Academy of Sciences, January 13.

K. Strubecker : Theory of circular quadratic complexes.

H. Güntert : Development of the folds of the mucous membrane of the intestine of *Salmo irideus* Gibb.

F. Urbach and A. Wolinski : Spontaneous change of the latent photographic image. If a photographic plate is illuminated by red light during its exposure to actinic light, the latent image is partially destroyed. This effect is much smaller if there is an interval between the formation of the latent image and its exposure to red light. It is concluded that the photo-chemical reaction products are unstable when first formed but become stabilized with lapse of time. The course of this stabilization has been followed over 20 hours.

A. and R. Skrabal : Kinetics of the hypochlorite and hypobromite reactions. The formation of chlorate in hypochlorite solution and of bromate in bromine bleaching solution has been studied. Among other results, the dissociation constant of hypobromous acid at 25° has been determined as 2×10^{-11}.

E. Abel and F. Fabian : Some halogen equilibria in heavy water.

O. Reithofer : New Tertiary outcrop at Wórgl in the Unterinntal.

January 20.

Elisabeth Rona and J. Schintlmeister : α-Rays of mesothorium 2. A study of differential absorption curves by means of proportional counters shows that if mesothorium emits any α-rays, the branching ratio between α-rays and β-rays is less than 2×10^{-4}.

O. Peczenik : Antagonistic effect of thyroxine and of diiodotyrosine on the heart-depressing action of pitressin.

J. W. Breitenbach : Thermal polymerization of styrol.

Zdenko Herrmann : Components of the Leclanché cell (2). The role of the soot.

E. Jusa and A. von Janovich : Azo-colours from aryl esters of 2-oxy-3-naphthoic acid and of 1-oxy-2-naphthoic acid.

H. Dostal : Elastic properties of solids of high molecular weight.

G. Flumiani and V. Bajic : Synthesis of oxy-anthraquinone. A new synthesis of metal salts of oxyanthraquinone (1).

O. Burkard and L. Kahovec : Studies of the Raman effect. (82) Nitrogenous substances. (10) α-Aminopropionic acid, α-oxypropionic acid and their esters.

Forthcoming Event

Thursday, April 21

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Storey's Gate, S.W.1), at 6.30.—Prof. J. E. Younger: "High Altitude Flying".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant Lecturer in Engineering in the Swansea Technical College—The Director of Education, The Guildhall, Swansea (April 21).

Senior Technical Officer at the Air Ministry Headquarters—The Secretary, Air Ministry, S 2 (d), Adastral House, Kingsway, London, W C.2 (April 22).

Instructor in Automobile Engineering in the North Gloucestershire Technical College, Cheltenham—The Secretary (April 25).

Lecturer in Mechanical Engineering in the Constantine Technical College, Middlesbrough—The Director of Education, Education Offices, Middlesbrough (April 30).

Assistant Archæologist in the Ordnance Survey Department—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1 (April 30).

Professor of Anatomy in the London Hospital Medical College—The Academic Registrar, University of London, Senate House, W.C.1 (May 3).

Assistant Lecturer in Chemistry in the Royal Agricultural College, Cirencester—The Principal (May 16).

Assistant Lecturer in Chemistry in the Bradford Technical College—The Director of Education, Town Hall, Bradford (May 14).

Lecturer in Physiology and Hygiene in the Bergman Osterberg College, Dartford—The Principal.

Medical Inventions and Discoveries

THE report of the Medical Research Council for the year 1936–37 recently issued* refers to the present unsatisfactory position in Great Britain of the medical treatment known as chemotherapy, which consists in the administration of chemical compounds synthesized in the laboratory and found to have specific actions on the infective organisms causing particular diseases in man and animals. The discovery and production of chemical compounds of value in this way have, the report states, "depended almost entirely on German science and industry, and still so depend", although the subject has special significance for the British Empire with its immense responsibility in tropical countries. Malaria, for example, still holds the premier place as a cause of premature death and inefficiency in the Empire, and it is estimated that in India alone at least 100,000,000 persons suffer from the disease each year, with a direct financial loss variously estimated at from £23,000,000 to £50,000,000 per annum, the indirect losses being still greater. The report then continues as follows:

> "Were the matter only one of prestige, the situation would be serious enough, but the financial aspect is also of much importance. Foreign firms have built up large organizations and have spent large sums of money to advance this aspect of therapeutics. They naturally, therefore, expect to derive substantial profit from any practical discoveries. Not only do they take out comprehensive patents to cover these chemical agents, but they do not as a rule grant licences for manufacture in this country; in case of war, therefore, the British Empire might be deprived of essential drugs, as in the case of salvarsan compounds in 1914."

The success of Germany in the field of research in chemotherapy has been dependent on a system in which the investigations have been made chiefly in large research establishments maintained by manufacturing firms which have employed hundreds of chemists and have persevered for years before achieving results capable of commercial development. In Great Britain, manufacturing chemists, it is stated in the report, "have not appeared willing to use their resources in this manner", the main interests of the larger firms having been in other directions, while the smaller firms have been either unable or unwilling to undertake research of this kind. The report continues, "in these circumstances, the only possibility of securing that this country took its proper part in the matter, in relation to its imperial responsibilities, was a national scheme supported from public funds." A commencement is therefore being made with such a national scheme supported from public funds, for a sum of £30,000 provided by Parliament has been allocated by the Council "for research in chemotherapy, in the first instance in respect of the cost of the new buildings required", and it is stated that such a scheme would attempt to follow with Government support the general line of action of a great commercial organization taking up this subject of research. Presumably the scheme would be under the control of the Council and, so far as is indicated in the report, would operate without the direct co-operation of industry.

It is not clear on what grounds the Council bases its opinion that in existing circumstances the *only* possibility of securing that Great Britain may take its proper part in the matter is such a national scheme supported from public funds. Presumably one of the grounds is the inference that because, as alleged, manufacturing chemists in this country "have not appeared willing to use their resources [for research] in this manner", they are now and will continue to be unwilling. There is, however, no substantial evidence in the report that the manufacturing chemists either have been or are at present unwilling to use their resources in this manner. On the other hand, evidence from other sources supports the opposite opinion, at least in so far as concerns certain manufacturing chemists, for in 1931 a scheme for the compulsory dedication of patents to the public and their administration by a State department was submitted to the Departmental Committee on the Patents and Designs Acts by a Joint Chemical Committee representing several chemical institutions, and it was stated that the scheme might be regarded as the expression of opinions held in common by most of those concerned in the practice of chemistry in Great Britain. It is clear, therefore, that in 1931 these manufacturing chemists were willing to co-operate, and there is no reason to think that they are less willing to do so to-day ; indeed, there is reason to believe from recent statements in the Press that they are not only willing but even anxious to co-operate.

---

* Committee of the Privy Council for Medical Research. Report of the Medical Research Council for the Year 1936–7. (Cmd. 5671.) Pp. 195+xiv. (London: H.M. Stationery Office, 1938.) 3*s*. net.

There was, however, opposition to the scheme put forward by the Joint Chemical Committee, and the Departmental Committee reported that although no question considered by it had attracted more attention or been the subject of more conflicting evidence, the definite conclusion had been reached that no sufficient case had been made out for any compulsory dedication.

In view of this definite conclusion and of the lack of evidence to support the circumstances on which the Council bases its opinion as to the only possible scheme, it may be pointed out that there are now in operation in other countries at least two quite different schemes in each of which science and industry are co-operating with one another.

The first is a scheme for the voluntary dedication of medical patents, which is in existence both in Canada and in the United States. In Canada, the ownership of the insulin patent was placed in the hands of the University of Toronto, and has since been efficiently administered by that authority, and in many foundations in the United States there have been drawn up rules regulating the conditions under which patents may be dedicated to them. In the United States, during the past few years, there has been a growing recognition on the part of university administrators that only through the proper use of the patent system can the public benefit of certain of the inventions which are made in their laboratories be ensured and the undesirable aspects of patent exploitation avoided. It is felt in that country that mere publication of a scientific paper disclosing an invention does not prevent patenting of the invention by some individual with a hazy fragmentary prior record along the same general lines. The inventions may easily get into unscrupulous hands and the public may be exploited through this unforeseen result of a programme of institutional research. There is, however, no substantial evidence that opinion among medical men and manufacturing chemists in Great Britain would favour the adoption of a scheme for the voluntary dedication of medical patents.

The second scheme in which science and industry are co-operating is that which has already been established in Germany with such satisfactory results to that country and such unsatisfactory and even dangerous results to our own country. According to the report of the Medical Research Council, the discovery and production of compounds of value in chemotherapy have "depended almost entirely on German science and industry, and still so depend", and in the opinion of the Council the difference between the practice in Germany and the practice in Great Britain is that whereas in Germany large research establishments maintained by manufacturing firms have employed hundreds of chemists and have persevered for years before achieving results capable of commercial development, British manufacturing chemists have not appeared willing to use their resources in this way. There is, however, another important difference, produced by the fact that medical men in Great Britain have not readily given their co-operation to test a therapeutic agent that is the subject of proprietary rights. In the evidence submitted by the Medical Research Council to the Departmental Committee on the Patents and Designs Acts it is stated that :

> "There is not there [in Germany] the same feeling against the taking of patents by medical men, and many physicians attached to public hospitals and University Clinics are ready to investigate new remedies on behalf of a commercial patentee, on a footing similar to that of the consulting chemist."

It should be remembered also that manufacturing firms are placed under other serious limitations in respect of medical patents by the law of this country. For example, by Section 38A of the Patents and Designs Acts, 1907–1932, a medical patent must be of defined limited scope and "the Comptroller shall, unless he sees good reason to the contrary, grant to any person applying for the same, a licence" to use the invention; and again, by the Therapeutic Substances Act, 1925, a scheduled therapeutic substance may be manufactured only under licence, and a Joint Advisory Committee consisting of representatives of the Ministry of Health and medical and scientific bodies fixes the standards of purity, strength, etc.

In view of these facts, it is not clear either that the circumstances alleged by the Medical Research Council have a sufficiently firm foundation on which to base its opinion as to the only possible scheme, or that the scheme proposed is the one most likely to attain the desired end. Is it to be seriously contended that a scheme controlled solely by British science without the aid of British industry will be able to displace German science and industry, working in harmony, from the strong position in chemotherapy which they already hold in Great Britain? Would it not be better in making a forward step to try once again to follow the path which has led Germany to success through willing co-operation between science and industry, than to embark on an uncharted course controlled solely by science without the willing co-operation of industry? The immense responsibilities of the British Empire in tropical countries and the dangerous position of Great Britain in the event of war seem to make it imperative that, before any untried plan is proceeded with, every possible effort should be made by all the parties concerned—scientific men, medical men, and manufacturing chemists—to evolve a scheme of the kind which has already brought success to Germany, whereby the willing co-operation of science and industry will rectify our unsatisfactory peace-time position by rendering the country independent of foreign supplies of chemotherapeutic drugs.

Knowledge and World Progress

World Brain

By H. G. Wells. Pp. xvi+130. (London: Methuen and Co., Ltd., 1938.) 3*s*. 6*d*. net.

THIS, the latest of Mr. Wells's books, may well be the latest-but-one before this review appears, so swift is the rush of his ideas, so urgent the message which he has for a civilization clattering blindly towards chaos. Here, as in so much of his work, we have yet another contribution towards that orderly world-scheme so dear to the heart of the ever-young, wise and keenly interested recruit to the ranks of the septuagenarians. The essays collected in the hundred and thirty pages of this slight and engrossing volume comprise a Friday evening discourse delivered at the Royal Institution, a lecture given in America, a contribution to the Encyclopédie Française, the presidential address to Section L of the British Association on "The Informative Content of Education" and a series of appendices evoked by the comments of those sensitive souls ruffled by the more provocative parts of his addresses.

For provocative Mr. Wells is—and long may he remain so! To some he may, now and then, seem to lay more stress on the material than the spiritual factors that have contributed to the making of history. As when he tells us that "in the middle-nineteenth century all Europe thought that the United States must break up into a lawless confusion. The railway, the printing press, saved that." That is a literal truth. But the mind of Abraham Lincoln, a man as great as some of the strutting leaders of a later age are small, was surely the determining factor in the preservation of the Union.

These divagations, however, are but incidental, and in most of these addresses Mr. Wells seldom wanders far from his main theme—the gathering, indexing, digesting and clarifying of the sum total of present knowledge into an ever-changing, ever-growing World Encyclopædia, which shall not only serve the needs of the specialized student, but also shall give to the citizen of the nation of to-day something of the factual and critical knowledge necessary to make easy his progress towards citizenship of that world-federation to which he is, paradoxically enough, stumbling through a phase of intensified nationalism.

There never was a time in the history of mankind when it was more necessary that this ordered knowledge should be at the beck and call of all of us—when the elements of success are in the hands of those who can combine an emotional drive towards the light with an intellectual appreciation of the difference between the true and the false dawn.

There's the rub. The two elements must be present and, whereas the emotions are easily, too easily, aroused, it is the hardest task in the world to persuade men to think objectively. In his so-called reasoning on matters directly concerning his relations with his fellows, man for the most part is content to allow a series of fleeting images to pass before his mind. He stamps down those he dislikes, seizes on those that appeal to him and terms the process "coming to a reasoned judgment". The result may be seen in a conversation overheard just after the Austrian coup—a conversation which is, as near as may be, reported *literatim* :

A : "Thank heaven we'd no League of Nations functioning this week-end—we'd have been in the middle of a first-class war now."

B : "Don't you think it would be more accurate to say that if we'd had a League of Nations this situation would never have arisen ?"

A : "Not a bit of it. Anything like the League means that England's left to hold the baby—as we were when Wilson founded his blessed League, and then cleared out and let us down."

B : "Do you really feel that that's an accurate account of what Wilson did ?"

A : "Near enough. Anyway, we disarmed to the bone, to set a good example—and much notice anyone else took of us."

B : "Have you ever drawn curves of arms expenditure year by year to see if there was a dip in British expenditure that wasn't present in that of other countries ?"

A : "No—and I don't intend to. And if there wasn't a dip it was because money was spent in wages that should have been spent on ships."

There was more to the same tune.

And now remember that *A* is a well-to-do and competent man of business, multiply him by some millions, think of his like in other countries, and we see only too clearly that here is an immense mass of material not likely to be influenced in the slightest measure by the content of any World-Encyclopædia.

Not that there is need for despair on this account. Mr. Wells, himself perennially youthful, makes his appeal to youth and to those whose minds have not acquired an incurable wry-neck in the course of the process called education. Every year saved from war is a year gained to this end of education for world-citizenship. But what of the particulars of that education—how, in Rutherford's phrase, to "get on with it" ? In these brilliant and discursive addresses, Mr. Wells has sketched a general plan and has, very reasonably, not condescended to detail. Schemes may be over-elaborated and static on that account. In his own wise words, "If a thing is really to live it should grow, rather than be made." But a start must be made somewhere and somewhen. Is it possible, *now*, to provide John Smith at least with pointers that will direct him to objective, critical and unbiased information concerning—well, concerning a thousand-and-one matters about which he should be conversant—the causes of the world war, the reasons for the great depression, the tragic story of these wasted twenty years, the meaning of money, credit, world-trade, Bolshevism, Communism, Fascism—how many of those whose votes may decide the fate of the world have the beginnings of knowledge of topics bandied about on all political platforms ? If Mr. Wells would continue the good work he has initiated in the volume under review, he would add very sensibly to the heavy debt which the civilized world already owes him.

ALLAN FERGUSON.

Pliny Revived

The Mind of the Ancient World: a Consideration of Pliny's Natural History. By H. N. Wethered. Pp. xv + 302. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1937.) 12*s*. 6*d*. net.

THIS book is a good example of a process which will become more and more necessary as time goes on. There are masses of old literature, full of interest, much read and very important in their day, which it is impossible for us now to read in their entirety, but which it would be a grave loss to let die. Pliny was one of the finest characters of the ancient world, highly cultivated, very busy and useful in public service under his friend the Emperor Vespasian until A.D. 79, when he was suffocated in the eruption of Vesuvius. He gave the greater part of his too short life to incessant study and compiling his "Natural History", or "Survey of Nature", which was an encyclopædia of knowledge and legend about everything in the world of which men talked or had written in his time. This great book, which Humboldt thought surpassed in the richness of its contents any other ancient work, was translated at the beginning of the seventeenth century into delightful Elizabethan English, by Philemon Holland, a few years before Sir Walter Raleigh published his "History of the World".

Both books, famous and much enjoyed in their day, are now almost entirely neglected, and Mr. Wethered has had the happy idea of extracting the gems of Philemon Holland and connecting them by a very well-informed and sufficiently critical running commentary of his own, which gives us all the best of Pliny without allowing us either completely to discredit him or to accept all his amusing fables as gospel truth. The result is a very useful and an extremely interesting book. One's only criticism can be of its main title, for it cannot be said that Pliny's work adequately represents "The Mind of the Ancient World". He was not a serious thinker, but a compiler of everything, writing or gossip, which he came across. A book in which we find none of the philosophy or mathematics of the Greeks cannot properly be said to describe "the mind of the ancient world".

But for what it is—a gossiping encyclopædia of ancient lore—there is nothing comparable. The book is the source of most of the legends and best-known stories of Greece and Rome. Here is Cleopatra's pearl drunk off in a cup of "sharp vinegar" and Polycrates' sardonyx ring brought back to him in the body of a "mighty fish", and the dolphins that waited for the little boys and carried them on their backs and died for grief when they lost them; and a host of others. But it would be a great mistake to dismiss the general picture which Pliny gives us of the ancient world on account of his delightful credulity for interesting stories. Most of them are told just as good stories commonly believed and, though he is not a careful scientific observer, he sometimes intimates a want of credence for certain things. For the bulk of what he described he is as reliable as Herodotus and, of course, far more detailed. Herodotus, the father of history, has a story to tell and the personal and social details are incidental. Pliny sets out to paint a picture of the world and of men as he saw them and is the father of encyclopædists, even, one might say, of 'descriptive sociologists'. We gain from him a realization of the elaborate civilization and luxury of his times which we should not have acquired elsewhere; and he adds to his description a very proper moral indignation at much of what he describes. "What folly and madness in the devil's names is this", is the sort of exclamation which keeps falling from his lips when he describes the doings and the waste of men like Nero, who had just passed away.

Pliny is specially rich and valuable on two sides; one, the full description of plants and vegetables and the use made of them; the other, the work of painters, sculptors and artificers generally. In the former case, one is amazed at the wide and often very intelligent use made of herbs and vegetables by men of all classes. The lettuce was in as much repute as with us, and the cabbage much more so. Eighty-seven different remedies were attributed to the cabbage and scores of others to garlic, onions, asparagus and radish. But it is probably as the source of material information as to painters, sculptors and artificers of all sorts that Pliny has enlightened us most. The Seven Wonders of the World, and many other things still more wonderful as craftsmanship, are described in full and fascinating detail. The sorts of marble and of gems or colours stand out in vivid relief. He does not philosophize about the art but pictures the artists' work and gives the personal anecdotes about them that had been handed down.

On two other sides, if not philosophical, Pliny yet leaves a strong moral impression. One relates to the feelings of men generally in his time, the other to his own religious leanings. There was undoubtedly a much stronger sense for beauty than among ourselves, even in the case of men like Nero who were stained with every crime. Nero was passionately fond of certain gems and colours. Beautiful buildings, statues and decorations aroused far keener admiration in him and all of his time than they do with us. For himself, Pliny leaves us one or two immortal sayings, on the unity of Nature and the nature of the divine. He was no atheist, but he had no moral use for the mass of gods and goddesses of ancient mythology. "These beliefs, I say, are mere fooleries, little better than childish toys. Whereas in very truth a god unto a man is he that helps a man; and this is the true and direct pathway to everlasting glory. (Deus est mortali juvare mortalem, et haec ad aeternam gloriam via.)"

F. S. Marvin.

Animal Collecting

Animal Treasure

By Ivan T. Sanderson. Pp. 325. (London: Macmillan and Co., Ltd., 1937.) 12*s.* 6*d.* net.

"Animal Treasure" is not a chronological narrative of a sojourn in the wilderness, although naturally some regard has to be paid to the lapse of time. It is a most readable and lively account of some of the things seen and heard by the author and his two companions during a stay of about eleven months in the forest of the Cameroons and for the most part at a distance of about 250 miles from the coast.

There are many descriptions of the living and frequently unalarmed animals. One must use the latter qualification, since, for example, the lemur on p. 127 was, if not frightened, very angry, and the entire local mammalian fauna, including all the primates, on pp. 128–131 was suffering from the most diverse and undignified emotions. That Mr. Sanderson is as accomplished with his pencil as his pen is shown by the illustrations, the majority of which are a pleasure to the eye.

Through the liveliness of the text there is allowed to appear hints of the industry by which this expedition brought together a very large and varied collection of the smaller mammals, of reptiles and amphibians and of crustaceans and arachnids.

Mr. Sanderson was evidently on the best of terms with the native population and found them very valuable collectors and preparators. It may be permitted to remark that the taste for chitterlings is not a peculiarity of the Negro race (cf. p. 185). These delicacies are appreciated in the Argentine and the name has been known in English since 1280.

It is rather surprising to find a person with the sophistication which Mr. Sanderson at least suggests that he possesses allowing himself the naivety of attacks on Christians and Europeans. One cannot help feeling that but for these despised creatures the author's experiences from the time of his landing might have been quite different; it is surely a little ungrateful. But it is verging on impropriety for a professing man of science to regard any animal with the emotions Mr. Sanderson seems to feel for spiders, shrews and hawks. It is not the duty of a collector to kill and waste: the persistent killing of the hawks can have no excuse.

Mr. Sanderson, as a schoolboy, was disappointed in the old methods of collecting, but he does not clearly describe a new one. His own do not appear to have been particularly original, and it may reasonably be concluded that they were those which are in general use.

It may well be that the publishers have exceeded the author's intention by describing the book as "among the serious works of science" on the back of the jacket. This it certainly is not. Some of the statements have been seriously challenged by Mr. Arthur Loveridge in the *Scientific Monthly* of January 1938, and even if he is refuted, the fact remains that the zoological parts are so mixed up with general narrative and discourse as entirely to avert the idea of seriousness, and there is not even an index to enable the grain to be separated.

It will be interesting to see what new facts appear from Mr. Sanderson's field note-books in the reports on the collection which will doubtless be published.

Although there may be species of such rarity that examples of them would be welcome even if almost devoid of data, the idea of a new sort of collecting is an attractive one and may be considered in a little detail. A moment's consideration will show that what is really wanted is a strong effort in the field to fill in the gaps not only in the dead series in museums but also in our knowledge of the animal "in his habit as he lived". It is, of course, an ideal probably unattainable to expect that a complete picture can be made for every species, but if the field worker could find out beforehand what forms should be the objects of special concentration, much might be done. What is wanted is not only a long series of specimens of both sexes and all ages from which it can be shown what occurs in the way of growth and change and individual variation: with this should be coupled descriptions of the animal in life, even, if it is soft bodied, including its shape and of part at least of its physiology, not quite in the textbook meaning but with regard to the two survival functions, that of the individual—feeding and protection from destruction, and that of the race—method, time and place of breeding. With these might be linked observations on behaviour; not the reaction of the animal to interference, which is easily seen in the laboratory, but the manner in which it goes about its business and reacts to the stimuli provided by its environment. From such knowledge one may hope, for example, to be able to recognize apparent eccentricities of distribution in time or space as normal features of the routine of species. Further, is it inconceivable that some of the obscure problems of phylogeny might be illuminated by a study of the living creature? If descent show itself in hard or soft tissues, is it too much to expect that it will also be exhibited in the way in which they function?

It is possible that data exist for such 'descriptions' but they are seldom met, although in ornithology and entomology the tendency towards them exists. Specialists innumerable are constantly adding to the existing vast mass of knowledge, but they too seldom unite with a common goal in mind.

Some kind of intelligence, in the military sense of the word, is needed. It should be the function of a section of zoologists to correlate the information produced by the specialists. Although there may be a million species known, so that the first view of the task is appalling, the scientific spirit does not shrink on account of the magnitude of what lies before it, if the thing has to be done. In darker moments it seems that only by a union with the work of the field naturalist can zoology be saved from becoming a synonym for necrology, if one may introduce a new meaning for that word.

J. E. Hamilton.

Social Anthropology of North American Tribes:

Essays in Social Organization, Law and Religion. Presented to Prof. A. R. Radcliffe-Brown upon the occasion of his accepting the Chair of Social Anthropology at Oxford University. By Fred Eggan, William H. Gilbert, jun., J. Gilbert McAllister, Philleo Nash, Morris E. Opler, John H. Provinse, Sol Tax. Fred Eggan, editor. With an Introduction by Robert Redfield and a Bibliography of Prof. Radcliffe-Brown by Ina Corinne Brown. Pp. xvii + 456. (Chicago: University of Chicago Press; London: Cambridge University Press, 1937.) 13*s*. 6*d*. net.

THE announcement of the departure of Prof. A. R. Radcliffe-Brown from the University of Chicago to become the first professor of social anthropology at Oxford inspired certain of his pupils to produce this volume, commemorating his work for the study of social anthropology in the United States during the past five years.

As his colleague Dr. Robert Bedfield reminds us in an introductory appreciation, Prof. Radcliffe-Brown's theories of the method of social anthropology have become something of a storm centre in the United States. They aim at a scientific sociological methodology on the lines laid down in his presidential address to the Anthropological Section of the British Association at its London meeting, in contradistinction to the 'historical' view which has grown out of methods followed by Franz Boas, and the individualistic and psychological methods of E. Sapir and Margaret Mead. Hence this volume is something of both a demonstration and a manifesto. It certainly contains some interesting experiments in method which form a striking contrast to those familiar in the writings of American social anthropologists, and, furthermore, had already been applied to some of the material reviewed here.

Of the essays included in the volume—nine in all—perhaps the most instructive from the point of view of the student of method is that on "Some Problems of Social Organization" by Dr. Sol Tax. The author, after setting out some of the more general questions, for which it is the aim of social anthropology to provide a solution, attacks the kinship terminology of certain Indian tribes of California, who follow the so-called "Omaha" and "Crow" systems respectively. It is interesting to note, however, that in arriving at his conclusions as to the place of these systems as determinants in organization and behaviour, he felt constrained to depart so far from his teachers' strictly sociological concepts as to admit psychological factors.

Glossary of Physics

Compiled and edited by Prof. LeRoy D. Weld, with the collaboration of a large group of Consultant Physicists. Pp. x + 255. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 15*s*.

THE rapid development of physics during recent years has, of necessity, required a very large addition to its vocabulary. In reading the literature of a particular branch of the subject in which one has not specialized, one comes across unfamiliar terms; in such instances to have an accurate glossary to hand is of the greatest use. Prof. Weld and his collaborators deserve the warmest thanks for providing such a glossary. We can well believe that it was "impracticable to make sure of complete agreement among the various persons concerned on each of the many definitions and statements"; but although perhaps a few experts may not favour a definition here and there, the vast majority of physicists and those concerned with its manifold applications will find this an indispensable volume. A pleasing feature of the book is the inclusion of references in connexion with most of the terms, which enable the reader to gain supplementary information.

The book is well arranged and produced, and of convenient size; we hope that the demand for it will justify the issue of future editions at a price that the average physicist is more likely to be able to afford.

H. R. L.

The Theory of Continuous Structures and Arches

By Prof. Charles M. Spofford. Pp. xiii + 267 + 12 plates. (New York and London: McGraw-Hill Book Co. Inc., 1937.) 21*s*.

THE first chapter of this book deals with continuous structures, and the last is devoted to rigid frames. Apart from these, the text is mainly concerned with arch types, and the applications of the methods of arch analysis to bridge forms. The usual lines of theory are developed effectively. Applications are made with thoroughness and with an explanatory power and detail of evaluation that demonstrate a full knowledge of the problems of design of this class. Two-hinged arches of parabola and segmental types receive very full attention and the treatment of fixed arches is adequate in scope. There is an interesting presentation of the results of photo-electric researches on rigid frame forms and some instructive plates of bridge construction.

Although the treatment is somewhat less wide in scope than the title, the book is well planned and developed for advanced students of bridge theory and design.

Grundriss der allgemeinen Zoologie

Von Prof. Dr. Alfred Kuhn. Fünfte, verbesserte und vermehrte Auflage. Pp. ix + 272. (Leipzig: Georg Thieme, 1936.) 9.80 gold marks.

FORMER editions of this excellent text-book, with its comprehensive and well-balanced contents and clear illustrations, have been favourably noticed in Nature (112, 200; 1923: 129, 925; 1932). It need only be added that many changes in the text show that the fifth edition has been brought up to date. In some places, precision has been given to the already succinct descriptions of the characters of phyla, the section on development has been modified to meet modern views, and a short chapter upon the ecological distribution of animals includes a discussion upon the relationship of species in parasitism and symbiosis. We think it may still be said that there is no English book quite like this introduction in the success with which it lays, in so limited a space, a broad foundation in the morphology, physiology and development of the animal kingdom.

Gliding and Soaring Flight*

By Prof. D. Brunt

THE early history of gliding is the early history of flying in heavier-than-air machines of any kind. The machine was projected into the air either from a hill-top or from flat ground, and came down slowly while moving forward. Lilienthal described in his book on "Bird Flight as the Basis for Aviation" how in some of his earlier experiments in gliding over slopes the machine actually soared, or gained in height, being carried upward by the air current flowing up the slope. But the early pioneers soon became absorbed in the problem of developing a power unit, and the development of the petrol engine, by making the aeroplane possible, diverted attention from the possibilities of pure gliding. In Germany gliding was taken up as a sport soon after the Great War, and in 1922 the achievement of Martens in soaring for an hour gave a new impetus to the movement. The *Daily Mail* organized a gliding meeting at Itford Hill in 1922; but this failed to produce any permanent interest in gliding in England. It was only at the end of 1929, after the Germans had shown that the glider need not be bound to a hill-slope, but could soar under and into clouds, and could ride the front of an advancing storm, that interest was at last aroused in Great Britain, and that there came into existence a real British gliding movement. After undergoing the usual pangs of adolescence, this movement is now approaching the adult stage.

There has not been any very revolutionary change in the design of sailplanes in recent years, and it may be said that in appearance the modern sailplane resembles the power monoplane, without an engine, but with a more closely streamlined form. Differences occur in the wing-structures used, the strutted wing being generally lighter than the cantilever wing. Perhaps the most important change made in recent years has been in the direction of increasing the strength of the structure, in order to make it capable of standing the strains to which it may be subjected during flight in clouds. The stoutness of the fuselage is dictated, not by the demands of flight, but by the necessity of the structure being able to stand up to the strain of handling when on the ground.

In the early stages of training, the machine is launched by means of an elastic catapult, the ends being drawn by teams of men. Alternatively, the human power may be replaced by a horse or motor-car. Another method is to attach a cable to the front of the machine, and to wind it rapidly on a winch, thereby dragging the machine into the air, while another method is to tow the machine into the air behind an aeroplane. Sailplanes can fly at very low speeds without stalling, and consequently can be landed with safety in fairly small fields.

The modern sailplane has a sinking speed in still air of about 2–3 ft. per second, and so will soar in any vertical current the vertical component of which exceeds this modest value. The pilot of a soaring sailplane is in the position of an old lady trying to go down the up-escalator at a tube station, the escalator carrying her up faster than she can descend the steps.

For our present purpose we can define the problem of soaring flight as the problem of finding upward air currents of the necessary magnitude, that is, exceeding the sinking speed of the sailplane in still air, usually 2–3 ft. per second. For practical purposes, we can say that there are three classes of ascending currents in the atmosphere. First, when the wind blows against rising ground, it follows the contours of the ground, and if the upward component of the wind is sufficiently strong, soaring will be possible over the sloping ground. Secondly, when the air is unstable, convection currents may attain sufficient speed to make soaring possible. Thirdly, at the cold front in a depression, where a wedge of cold air pushes under a warm current, there is often sufficiently rapid ascent of the warm air to make soaring possible. Sometimes thunderstorms occur at cold fronts, and long flights have been achieved in the ascending currents in thunderstorms.

When the wind blows up the side of a hill the horizontal flow of the air is disturbed up to a height of about three times the height of the hill. A sailplane launched into the ascending current from the top of the hill can, by circling in the ascending current, attain a considerable height. If the pilot's aim is to make a flight of long duration, he can go to and fro above the ridge of the hill, and the duration of his flight is limited only by the duration of the wind in direction and strength, the pilot's physical endurance, or possibly the dangers of darkness. During the 1937 international competitions, two members of the English team, Messrs. Fox and Murray, flying the Falcon III two-seater, made a duration flight of 9 hours 48 minutes.

---

*Friday evening discourse delivered at the Royal Institution on March 5.

Long-distance flights cannot be made by hill soaring alone, but even when long-distance flights are attempted, they usually start with a gain of height over a slope, and on the way across country any slopes facing into the wind direction may be used to maintain or increase height, while the pilot waits for other types of ascending currents to turn up.

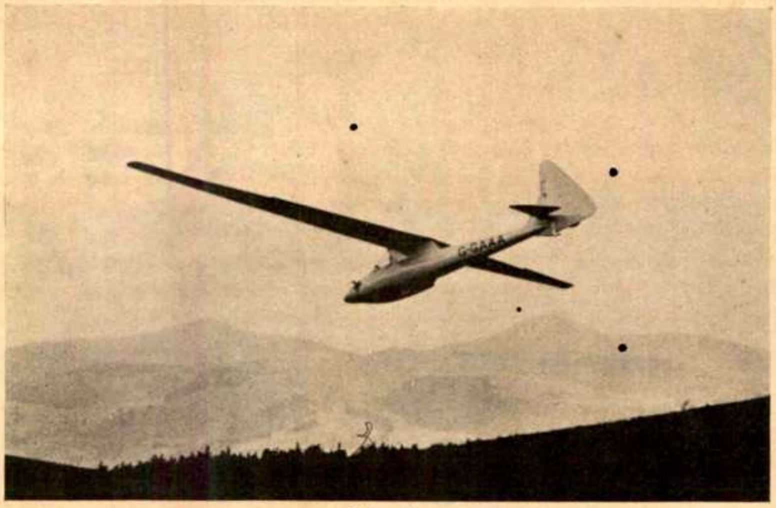

Fig. 2.
THE SAILPLANE *Hjordis* WHICH FLEW 104 MILES ON JULY 5, 1936.

The second type of ascending current, the convection current, occurs when the air is unstable, that is, top-heavy. Instability in the atmosphere requires a rate of decrease of temperature with height in excess of 5·6° F. per 1,000 ft. When this limit is surpassed, as is frequently the case when the sun is shining, and particularly on bright afternoons, convection currents (or 'thermals', to give them the name usually applied by the gliding men) are set up. Every convection current which carries warm air upward must be compensated by a descent of air somewhere. In other words, convection currents must possess some kind of structure.

In the laboratory it is easy to set up convection currents in a liquid or in a gas. The simplest illustration is afforded by pouring cheap gold paint into a shallow tray such as a mince-pie tray. The evaporation of the volatile liquid cools the upper layers, and so makes the liquid top-heavy. Looked at from above, the liquid is seen to be divided into a number of small cells, in each of which the liquid ascends at the centre, flows outward over the upper boundary, and descends at the margin of the cell. Similar effects can be readily produced in air. A convenient chamber for such experiments with air has a metal base, which can be heated electrically from below, and a glass top through which the motion can be observed, the motion being made visible by tobacco smoke. Such experiments may be regarded as reproducing conditions similar to those in the atmosphere when there is no wind. To simulate the effects of wind varying with height, the top glass plate must be capable of being moved across the chamber, dragging the air with it. It is then found that, if the instability is great, the bottom of the chamber being considerably warmer than the top, a slow motion of the top plate only distorts the shape of the cells obtained previously. If the bottom plate is not much warmer than the top plate, a slow motion of the top plate gives long rolls at right angles to the direction of motion of the plate. Such rolls are called transverse rolls. When the top plate is moved rapidly, the chamber is filled with long rolls in the direction of motion of the plate, and these are known as longitudinal rolls. The rolls, whether longitudinal or transverse, are in pairs, the two rolls in a pair

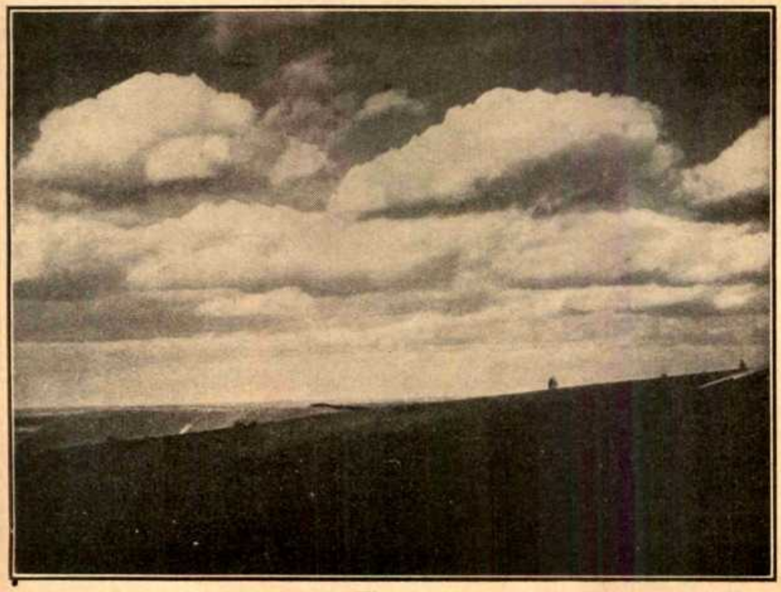

Fig. 1.
CUMULUS CLOUD CONSISTING OF A SERIES OF CUMULI JOINED UP IN ROWS.

spinning in opposite directions. Thus, when in the atmosphere conditions are unstable, the rolls of cloud formed by the upward motion of damp air will be at right angles to the wind if the wind speed varies only slowly with height, but along the wind direction if the wind speed varies rapidly with height. When damp air rises through a sufficient range of height, it produces cloud, and the cloud may be taken as an indication of the existence of the ascending current. If the wind does not vary with height, or if there is a calm, the clouds will usually be cumulus clouds, each forming the cap of an ascending current. When the wind increases rapidly with height, the cumulus clouds will form long irregular rolls (Fig. 1). Under any of these clouds the soaring pilot can find an ascending current, and under the long streaks of cumulus he can go the whole length of the cloud almost as readily as a car can go along a road. For this reason, such long cumulus clouds are generally known as 'cloud streets'.

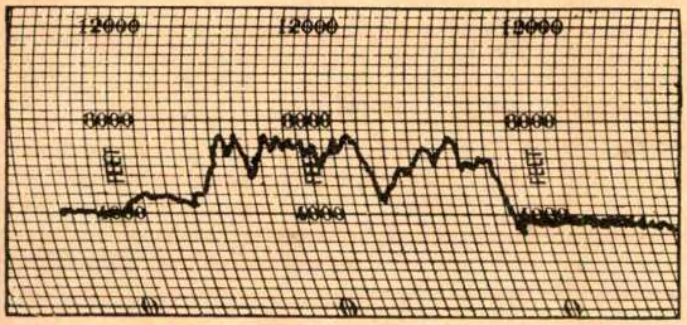

Fig. 3.

BAROGRAPH RECORD OF MR. PHILIP WILLS'S FLIGHT. THE FIGURES SHOW THE SCALE, NOT THE ACTUAL HEIGHT. THE LEVEL TRACINGS AT EITHER END WERE MADE BEFORE AND AFTER THE FLIGHT.

When the air is too dry to form cloud readily, it is not so easy for the soaring pilot to find the ascending currents. He then has to consider what types of ground are most readily heated by the sun, since it will be over the hottest ground that the ascending currents will form. Now it is possible to arrange types of ground in order of readiness with which they will heat up in the sun, as follows: sand, light soil over chalk, light loam, heavy loam, clay, water-logged soil, water. Any type of soil will heat up more readily when dry than when wet, more readily when bare than when grass-covered. The roofs of houses are heated more than grass fields, and the air trapped between the stalks of corn will be heated more than the freer air over a meadow. The air in woods will remain warm longer than air outside them, when the sun is low. Thus on a sunny day the pilot will look for thermals over villages, over large buildings, over any sandy or chalky patch surrounded by heavier soil, over cornfields surrounded by meadows. He will sometimes find thermals over land near the edge of any large body of water, and an asphalt road, which can heat up in the sun to as much as 25° F. warmer than surrounding fields, will very readily become a source of thermals when the sun shines on it. In the evening, thick woods on the side of a hill will produce thermals by the release of the warm air trapped within them during the day. Then the pilot will in the course of time find that there are certain spots in the neighbourhood of his usual soaring ground at which thermals are frequently formed.

Thus even in the absence of clouds, the sailplane pilot has certain principles to guide him. But, as Kronfeld once stated in a lecture at Darmstadt, the soaring pilot must fly with his head. By so doing he finds the thermal he needs. When once he gets into a thermal he can circle round in it until he has gained as much height as possible, during which time he will drift down with the wind. Alternatively, he can fly fast when he finds no ascending current, and slow down the moment he finds himself ascending, so as to gain as much height as possible in the ascending current.

As an example of what can be achieved, first consider that flight by Mr. Philip Wills on July 5, 1936, which holds the British distance record of 104 miles [see p. 745]. This flight was made in the sailplane *Hjordis* illustrated in Fig. 2. During the afternoon the sky showed scattered clouds, with short cloud streets here and there, a mile or two long and in series staggered relative to each other. The barograph chart (Fig. 3) shows how the pilot had to struggle to maintain height. The cloud base was very constant, at a height of about 3,600 ft., and so the pilot could never afford to lose much height. The lowest point on the chart, showing a height of about 400 ft. above the height of launch at Dunstable, and a height of about 800 ft. above the ground then immediately below, appeared to make a landing imminent, but at the critical moment a slight lift was found, and in 15 minutes the sailplane had gained 2,000 ft. This is an example of a flight made by circling in thermals, and staying in them as long as height was being gained.

The weather chart on that day showed no special indication that convection would be unusually active. There appear to be relatively few days on which it would be impossible for a sailplane to make a flight, if once it had achieved sufficient height to be able to wait for thermals to turn up. Distance flights are rarer than they need be in England because most of the soaring sites from which a start can be made have their soaring slopes facing westward into the prevailing wind, and so a start cannot be readily made when the wind is not westerly. Longer flights could frequently be achieved if the start were made by aero-towing.

The alternative to circling in thermals, variation of speed so as to go slowly in thermals, and fast when out of them, is exemplified by the flight from Berlin to Kiel, carried out by Ludwig Rotter on August 12, 1936. Rotter's sailplane, the *Nemere*, which has a sinking speed in still air of only 2 ft. per second, can fly at 87 miles per hour. During nearly the whole of the flight, the speed was maintained at 75–87 m.p.h., being reduced to 37 m.p.h. when flying through thermals. It was only in the later stages of the flight that the pilot did any circling in thermals. There was little cloud in the sky, but Rotter's barograph record shows that he was never in much danger of having to land from the time he was launched by aeroplane tow at a height of 1565 ft. The distance achieved was 203 miles, and the landing point was 138 miles off the direct line of the wind from Berlin. This flight illustrates the ability of a sailplane to travel across wind. Within the limits allowed by the strength of the machine, a sailplane can travel at any speed by gliding downward at a sufficiently steep angle. Thus by sacrificing height it can even travel against the wind, but it is not possible to achieve any considerable distance against the wind unless ascending currents are frequent and vigorous.

During a flight in South Africa, Mr. Philip Wills found that at times the convection currents were astonishingly vigorous, on one flight a height of 5400 ft. being gained in less than seven minutes. Wills has described how he shared thermals with the vultures, who treated him as one of themselves, flying in formation with him. It appears that the vultures partition the ground, each bird taking a territory of about a half-mile square, and that their existence is devoted to the search for two things, ascending currents, and food on the ground.

There remains to be discussed the third type of ascending current in the atmosphere, at the cold front in a depression. The Norwegian scheme of the anatomy of a depression shows on the weather chart a warm sector, separated from the cold air in the rear of the depression by a line which is known as the 'cold front'. This line is simply the intersection with the earth's surface of the upper boundary of the cold air, which lies in the form of a wedge with its nose some distance above the ground. The cold air pushes under the warm air, and forces it to rise over the nose, and, in some depressions at least, some of the warm air becomes unstable, so that it then rises freely to great heights, often giving a cloud which extends as high as 20,000 ft. The ascending current is often sufficiently vigorous to lift a sailplane to great heights, and once a sailplane has got into this current, it can fly along the direction of the front while being carried along with the front in its drift across country. Some remarkable flights have been achieved in this way.

We may note in passing that the fact that gliding is possible at a cold front, at heights of many thousands of feet, throws some light on the meteorology of the cold front. The slope of the upper boundary of the cold air averages about 1 in 50, and since we may assume that the ascending current must mount at a rate of at least 5 ft. per second if a sailplane is to gain height at a reasonable rate, it follows that if the ascending air were merely flowing up the slope of the upper boundary of the cold air, it would have a speed of 250 ft. per second, or about 166 m.p.h. This is far in excess of the winds in which cold front flights have been carried out, and so we may conclude that the ascending currents in which the flights were made were not due to ascent up the slope of the wedge. An examination of upper air temperatures measured just in advance of the cold front has shown that in some depressions the air is in such a state that if pushed upward through a relatively small distance, it will then rise freely.

When a sailplane pilot soars into the ascending currents below cumulus clouds, or near a cold front, he does not always find it easy to go just where he wishes. He is frequently drawn into the cloud, whether he wishes to enter it or not. Inside a cloud the air currents are frequently very irregular and violent, and the machine needs to be stoutly built if it is to stand this rough treatment. Further, the machine must then be piloted by the use of instruments which show any deviation from the horizontal, otherwise there is a risk of its coming out of the cloud in a nose-dive, or even upside down.

During the 1937 international competitions in Germany an English pilot, Flight Lieut. Watt, achieved a gain of height of 8,000 ft. in a cloud, taking about one and a half hours to do so. This is probably the best achievement in cloud flying which stands to the credit of a British sailplane pilot. Cloud flying has for some years been part of the normal advanced training of German pilots, but in Great Britain it is a recent development.

In Great Britain, gliding and soaring flight is purely a sport, while in Germany and Poland it is part of the normal early training of the power-plane pilot. In the latter countries, gliding and soaring flight is highly organized. It is perhaps invidious to make a direct comparison between the achievements of British and Continental sailplane pilots. The longer period during which gliding has been organized in Germany and other Continental countries, added to the fact that far stronger financial support is given by the Government in these countries than in Great Britain, makes a direct comparison at the present time a little unfair to British gliding. A comparison of distances achieved is particularly misleading, since Great Britain is, after all, a small country. For example, starting from Dunstable with a westerly or south-westerly wind, it is impossible to outdistance Wills's record flight of 104 miles by more than a few miles at most. At the international competitions last year, out of 297 launches for distance flights forty flights exceeded 100 miles; on the first day of the competitions three competitors flew from the Wasserkuppe to Hamburg, a distance of 351 kilometres (218 miles). Again, at the Polish National Competitions in 1937, the distance flights *averaged* more than 60 miles, the longest flight being nearly 200 miles. These competitions were held in the flat country in the north-west of Poland, in order to test the possibilities of soaring in flat country with launching by aero-towing up to heights of 1600–2000 ft.

The world's distance record for cross-country soaring is held by a Russian pilot, Rastorguyev, who set up three new records consecutively, of 335, 374 and 405 miles, all made during May 1937.

Enough has been said to show that long-distance flights can be made in sailplanes without serious difficulty. Gliding is a safe and healthy sport, and forms a useful preparation for training in power-plane flying. It also offers a means of adding to our knowledge of the processes of convection in the atmosphere, the glider being the only instrument which can be used for a thorough investigation of convection currents. While this may not help in the problem of forecasting to-morrow's weather, it is difficult to believe that increased knowledge will not eventually lead to increased wisdom.

Science, Logic and Philosophy*

By Dr. Harold Jeffreys, F.R.S.

SO long as an idealist confines himself to the description of sensations and to the construction of his ideal world, he can dispense with the theory of probability, but at the cost of having to reconstruct his world with every observation that does not happen to fit his laws exactly. An idealist that does not accept the theory of probability could expect the sun to rise in the west to-morrow, and nobody believing otherwise could make the slightest contact with him such as could alter his opinion. But he has no basis for inferring new sensations without it, because an infinite number of laws can always be made to fit any finite number of data. Without some rule for selecting the most suitable laws there is no reason to prefer any one prediction to any other, whether one is an idealist or a realist.

The naive realist is in an even worse position, because his strict causality leaves him with no margin of uncertainty at all; any random variation must either lead to a complete reconstruction of the laws, to a causal theory to account for the random variation itself, or to abandonment of science altogether. The first and third alternatives are seldom adopted; and the second merely points to some hypothetical causes as explanation—which is no explanation at all (1, pp. 244–248).

I conclude that naive realism as a scientific philosophy is simply wrong because it will not work in practice. It requires that we should know everything before we can say anything. Idealism and critical realism will work; the latter demands the notion of probability in any case; idealism also requires it if any inferences beyond the original data are to be made. Accepting the theory of probability, we can test the need to introduce any new parameter by comparison with the observations. The theory therefore gives an account of the actual process of successive approximation, the outstanding variation at any stage being taken as random until there is evidence to the contrary. This variation is as essential a part of the law as the systematic part. Thus we have the statement of Ockham's razor, in the form: Variation is to be taken as random until the contrary is shown[2]. This is the form needed for scientific purposes*.

The term 'unobservable', discussed in Prof. Dingle's recent article[3], is itself a legacy from naive realism. An observation, strictly, is only a sensation. Nobody means that we should reject everything but sensations. But as soon as we go beyond sensation we are making inferences. When we say that we observe an object we mean that we have, or have had, a series of sensations that are co-ordinated by imagining or postulating an object with assigned properties. The acceptance of a concept with its properties depends on the verification of the inferences that it leads to; that is, it is required that our sensations with it would be different from those without it. Hence the verifiable content of the hypothesis reduces simply to one or more new parameters in a law. This is dealt with completely by the theory of probability, and for purposes of inference nothing more is needed than the law itself. If we restrict ourselves to the inference of future sensations, the concept has done its work and serves no other purpose. This would be a possible idealist attitude. If we are realists and think that our concepts have something to do with an observable world (subject to the critical realist's willingness to change his mind if necessary) we may consider the law as a justification of the reality of the concept. But observability of a concept can mean nothing but the statement that the new parameters suggested by it are significantly different from those without it. Thus the theory of probability takes the rejection of unobservables in its stride. It gives an answer to the question whether any parameter is more probably present than not, given the actual data. To consider further data that we have not is mere waste of time. We need not say that so-and-so *must be unobservable*; we say that in fact, with the data at present at our disposal, it *is unobserved*, and that if we try to take it into account we shall probably lose accuracy.

---

*Continued from p. 676.

* It incidentally solves the problem of "scientific caution" Everybody agrees about the need for caution, but people differ about what caution means. Granting the possibility of inference from experience in any circumstances at all, we must begin with the hypothesis of randomness and test successive possible modifications of it. It is sometimes said that it is dangerous to apply a law far beyond the original data, but that is the best possible way to find out whether any modification is needed.

We now come to the alleged use of the principle of the rejection of unobservables in relativity and in quantum theory. Relativity (up to 1920 or so, at any rate) did not involve any new parameters; the velocity of light, the constant of gravitation, the mass of the sun and so on were all required by previous theories. It made changes in the laws but left them expressed in terms of the same parameters. The reason for abandoning the old theory was not that it involved unobservables such as absolute velocity or simultaneity; it was that this theory made positive predictions that turned out to be in disagreement with observation. The rejection of absolute velocity was not *a priori*, whatever later writers may have maintained; what was done in the special theory was to alter the laws of measurement and light so that they would agree with observation. The general theory, in its original form, was obtained by a natural analogy with Newtonian dynamics. The coefficients g_{ij} were seen to play the part of the Newtonian potential U. Far from matter all second derivatives of the latter vanish; near to matter the contracted Cartesian tensor $\nabla^2 U$ vanishes, but the separate components do not; inside matter $\nabla^2 U$ does not vanish.

Einstein proceeded by analogy. He found a second-order tensor that should vanish far from matter, contracted it to get the differential equations satisfied near matter, and said that these equations will not hold inside matter. Given, what was already established, that the Euclid-Newton system needed modification, this was the natural procedure to try. But it goes straight to the laws connecting measures; there was no philosophical necessity about it. The correctness of the law does not depend on any *a priori* arguments, which merely showed that it was worth considering, but on the fact that it required no new parameters and gave agreement with observation where the previous one failed (apart from one discrepancy, the node of Venus, which seems inexplicable by either theory). Insistence on the alleged philosophical grounds for the theory has led to their being challenged, and it has been a tragedy that arguments about a wholly imaginary philosophical basis have led to almost total neglect of the observational basis. The latter is, in fact, appreciably stronger than is provided by the mere verification, as I showed in Chapters vii–ix of "Scientific Inference". Starting entirely from observed data and proceeding by generalization of laws, introducing new parameters only when observation showed them to be necessary, I showed that it was possible by successive approximation to build up Euclidean mensuration, Newtonian dynamics, and the special and general theories of relativity; and that the form of the Einsteinian ds^2 is completely determined near the sun by observation alone. No further hypothesis is needed, and some of those made by Einstein are replaced by others more closely related to laws already adopted or by experimental facts. The object of the work was to see whether the observed agreement could be regarded as accidental; that is, whether any other possible laws could have given the same inferences in the range of magnitudes available; and it was found that any other form would require the introduction of an enormous coefficient as a new parameter. So far as any law can be proved by observation, Einstein's law is proved within the solar system.

The rejection of unobservables in the quantum theory, so far as I can understand it, seems to be merely a spring-cleaning. The older theories here involved many unobservable quantities, and left many observable ones unco-ordinated. It was apparently impossible to see the wood for the trees on account of the complication of the concepts, and some of the postulates were certainly wrong, since they led to conclusions inconsistent with observation. The modern quantum theories have begun by direct and successful attempts to co-ordinate what we know, without attending to the details of any deeper interpretation, and as a matter of method I think that their procedure is right. I should disagree, however, with the elevation of the rejection of unobservables into a magic philosophical principle. I do not claim any special credit for the fact that I tidy my room up when I begin to have difficulties in finding things; and in the quantum theory the important forward step did not come from the rejection of unobservables but from the subsequent recognition of formal relations. The relations are not inferred from a principle that so-and-so must be unobservable (and indeed they contain new unobservables of their own, which have to be eliminated before anything verifiable is reached), but are guessed by analogy and asserted because their consequences agree with observation, just like Einstein's law of gravitation. Here, however, the difficulty that I thought worth investigating in the latter is actively present, since different quantum theories at present do give the same observable results.

In this theory, the uncertainty principle has no sensational importance. It merely fixes a lower limit to the uncertainty that we should have with the most accurate types of observation that modern physics suggests; anybody not already blinded to the facts by naive realism and traditional deductive logic would have known that there is no such thing as a quantitative law that fits observations with absolute accuracy. The Heisenberg uncertainty is no new discovery in principle, but an estimate of a lower limit to the old uncertainty, which was never neglected except by misplaced optimism.

Many biologists speak respectfully of determinism, apparently because physicists do. One might have expected the nature of their data to save them from this. I think, however, that they have confused determinism with the possibility of making inferences at all; the test of a hypothesis in biology as in physics is the improvement of approximation, and the theory of probability is equally available for this purpose.

The theory of probability thus enables us to solve many of the major problems of scientific method, which are beyond the scope of traditional logic. It gives a formal account of the actual process of learning; it makes it possible to test laws by observation without making either the unnecessary assumption that laws can be found to fit observations exactly, or the certainly false one that the laws known to us at present do; it solves the problem of the rejection of unobservables; and it removes the paradoxical appearance of the uncertainty principle. It also provides an answer to the difficulty of the excluded middle, that is, that an unconsidered hypothesis may be the true one. When a law has been applied to a large body of data without any systematic discrepancy being detected, it leads to the result that the probability of a further inference from the law approaches certainty whether the law is true or not. In the usual language this would mean that the 'true' law differs so little from the adopted one that the two have been indistinguishable hitherto, and therefore will probably continue to be indistinguishable; thus the adopted one will probably continue to give correct inferences with the uncertainty stated in it. The better the verification of a law, the harder it will be to think of a valid alternative. The theory therefore makes it possible to modify a law that has stood criticism for centuries without the need to suppose that its originator and his followers were useless blunderers. At the same time it gives an answer to the problem of 'scientific caution'; this is best achieved by asserting no more parameters than are found significant, stating the results with the uncertainty found from the observations, and applying the law as far as possible beyond the original data (still allowing for the uncertainty of its parameters) until a discrepancy is revealed, if ever. It admits the whole of human experience as valid data, and any clearly stated hypothesis is worth testing. If the tests are found to reveal significant differences between people, it is still possible to proceed to study these differences and compare them with other data; psychology is admitted as a legitimate science.

We now return to the question of realism versus idealism; all the above considerations are applicable whichever we adopt. My belief in other people's personalities appears to be a generalization from experience of the usual type, and it leads to inferences about their behaviour, so many of which are confirmed that the natural procedure is to accept the existence as genuine while possibly proceeding to study the differences. In the question discussed at the beginning of this article I should say that the realist is definitely right. The belief in a material world is on a different footing, since while I seem to be immediately aware of my own personality, any object, even my own body, is known to me only through sensations. If I was an idealist I should say that I had invented it to give an account of my sensations; as I am a realist I think that I mean something more than that, but I admit that I find it very difficult to say what. In studying seismology I definitely believe that I am finding out something about the interior of the earth and not merely making predictions about future observations. But in either case the rival hypotheses could be tested only through the sensations predicted from them, and these by construction are identical. Thus apparently the theory of probability makes no decision whatever between critical realism and critical idealism, if the latter is taken as admitting other personalities ; both are legitimate hypotheses with probability $\frac{1}{2}$, and I can see no type of evidence that could alter this. I am speaking, of course, of the definite idealism that says that the world *is* nothing but an invention ; the indefinite idealism that merely says that it *may* be is the statement 'either definite idealism or realism is true', and cannot be used to deny realism. In any case it does not make the slightest practical difference which we adopt.

Cambridge Meeting of the British Association

THERE can be no doubt that the British Association, adaptable though it is to various environments, is most at home in an academic setting. This year's meeting in Cambridge ought, therefore, to be unusually happy, and the preliminary programme just issued affords prospects of this by more than one implication. Thirteen of the colleges—in addition to Emmanuel, where the secretariat will be housed—offer men the chance to return for a short space to the pleasures of college life ; Cheshunt College will be open for women, and other houses (including Girton) will accommodate both sexes. In addition to the University reception in the Senate House and Old Schools, conversaziones, pleasantly specified as 'informal', are announced in Trinity and St. John's, and the Mayor and Mayoress of Cambridge must surely be introducing a new and welcome feature into British Association programmes by inviting members to a sherry party, to be held in Emmanuel. It is to be hoped that the unusually early date of the meeting, August 17–24, dictated as it is by the convenience of the colleges and other authorities, will not dismay any of those who contemplate being present : it may be recalled in this connexion that the last Cambridge meeting, in 1904, took place at exactly the same time, but had nevertheless an attendance of 2,789, a figure far above the average for that period.

The presidential address, by Lord Rayleigh, will deal with "Natural Vision aided by Science", and a few lines which indicate its content may be quoted as an unusual but arresting feature in the programme. "The address," it is stated, "will show how, taking the eye as a prototype, most of the observational methods of modern science may be regarded as derived from it by successive modifications. A further part of the Address will deal with science and warfare, and will be directed to show that the relation between them is of the nature of an accidental by-product, and has in no sense been the primary goal of investigation."

The subjects of sectional presidents' addresses are announced as follows :

Section A (Mathematical and Physical Sciences) : Dr. C. G. Darwin, "Fundamentals in Physical Theory" ; Section B (Chemistry) : Prof. C. S. Gibson, "Recent Investigations in the Chemistry of Gold" ; Section C (Geology) : Prof H. H. Swinnerton, "Development and Evolution" ; Section D (Zoology) : Dr. S. W. Kemp, "The Future Development of Oceanography ; Section E (Geography) : Prof. T. Griffith Taylor, "Correlations and Culture, a Study of Technique" ; Section F (Economics) : Mr. R. F. Harrod, "Scope and Methods of Economics" ; Section G (Engineering) : Prof. R. V. Southwell, "The Changing Outlook of Engineering Science" ; Section H (Anthropology) : Prof. V. Gordon Childe, "The Orient and Europe" ; Section J (Psychology) : Dr. R. H. Thouless, "Eye and Brain as Factors in Visual Perception" ; Section K (Botany) : Prof. W. Stiles, "The General Physiology of the Plant Cell and its Importance for Pure and Applied Botany" ; Section L (Education) : Mr. J. Sargent, "The Proper Function of Administration in Public Education" ; Section M (Agriculture) : Prof. R. G. Stapledon, "Lay Farming".

Section I (Physiology) will not hold separate meetings, owing to the unfortunate clash of date between the British Association and the International Physiological Congress at Zurich. It seems strange that no mechanism to prevent such collisions has ever been devised.

The sectional programmes, even at this early stage, promise at least as diverse interest as usual. By way of examples among many subjects : Section A will deal with nuclear physics, high-altitude cosmic ray work, very low temperatures, and seismology. Section B promises a notable lecture-demonstration on gold films and their applications. Section C, among other subjects, will deal with the water supply of the county of London. Sections D and K will meet jointly to discuss the mechanism of evolution. Section G will consider problems of road and air transport, and will devote a special period to papers by junior workers. Section J will co-operate with Section D on questions of sense perception and the evolution of colour and pattern, and with Section L on the effect of the cinema and wireless on the life of the school child. Section L will discuss "Education for a Changing Society" in various aspects. Section M will consider agriculture in relation to national employment, soil conservation and enhancement of fertility, and crop and animal production.

The Conference of Delegates of Corresponding Societies will meet under the presidency of the Earl of Onslow, who in his address will discuss national parks, a subject to which the Association has properly given much attention. The evening discourses will be given by Dr. H. Godwin on the "History of the Fens", and by Prof. M. L. Oliphant on the "Contribution of the Electrical Engineer to Modern Physics". Of these, Dr. Godwin's discourse will be given on the Friday, thus appropriately preceding the Saturday excursions which will no doubt give many members a sight of the Fenland.

For the rest, full advantage will be taken of the exceptional opportunities offered by the various laboratories for exhibits and demonstrations, and certain special exhibits also are announced. Old scientific instruments will be shown under the auspices of the Cambridge Philosophical Society. There will be an exhibition illustrating the genetics of colour. It is proposed to have an exhibition of works of art by members of the Association—a feature, so far as records go, quite new to the programme. Members who would be willing to exhibit are asked to communicate with Mr. E. N. Willmer, St John's College, Cambridge. Photographs taken by members of the recent scientific delegation in India will be shown. It is intended also that two lectures shall be given on the work of the delegation, of which it is hoped that one will be by Sir James Jeans, who led the delegation as president of the Indian Science Congress.

Provision for excursions is as ample as ever: the range extends from Sandringham on one hand to the Gliding Club at Dunstable and Tring Museum on the other, and opportunity will be afforded for visits to points of beauty and interest in Cambridge itself.

News and Views

Prof. Max Planck, For. Mem. R.S.

Prof. Max Planck, originator of the quantum theory and emeritus professor of theoretical physics in the University of Berlin, will celebrate his eightieth birthday on April 23. Planck's work had a singularly direct influence on the development of modern physical theory. Beginning with purely thermodynamical studies—which have been embodied in his well-known text-book on thermodynamics—he soon applied both the descriptive and the statistical methods of thermodynamics to radiation, and was successful in finding a formula for the spectral energy distribution of black-body radiation which fitted the measurements and which could be deduced on the assumption that radiation is transferred from matter in quanta of energy proportional to the frequency ν. Successive editions of Planck's book "Warmestrahlung" show the development and variation of the original theory, of which the underlying physical idea remained for many years a mystery to physicists, although Planck's constant h was found to enter into various relations between radiation and matter, for example, in the photo-effect. It was not until Bohr explained the laws of spectral emission of atoms by a two-fold application of Planck's constant that this latter was recognized as fundamental for all kinds of atomic action.

In all this rapid development, Planck took a prominent, if cautious, part, with the result that his publications have long been considered as classics of German physical literature. His judgment largely influenced the development of contemporary physics. When Einstein's principle of relativity showed the way out of the axiomatic and other difficulties of electrodynamics, it was Planck who took up the idea and carried it through for mechanics and thermodynamics. Although many honours have been conferred on Planck, including the Nobel Prize in Physics in 1918 and the Copley Medal of the Royal Society in 1929, they have failed to spoil his simple and unpretentious ways. Confronted with the difficulties of the monetary inflation in Germany, Planck did not mind travelling a whole night on the railway in the old fourth class, in order to get to the Alps which he loved from his youth and in which a dolomite peak bears his name as the first to have climbed it. The German Physical Society is giving a banquet in the Harnackhaus on April 22 to celebrate Planck's birthday.

Sir Charles Peers, C.B.E., F.B.A.

The gold medal of the Royal Society of Antiquaries of London has been awarded to Sir Charles R. Peers in recognition of his services to archæology in Great Britain. This medal, generally accepted as the highest award in archæology in Great Britain, has been awarded on three occasions only, the first recipient being Sir Arthur Evans, who was followed by the Abbé Breuil and then Sir Aurel Stein. Sir Charles Peers, who was educated at Charterhouse and King's College, Cambridge, and is by profession an architect, was appointed inspector of ancient monuments under the Board (now Office) of Works in 1910. His appointment was the result of prolonged agitation by archæologists and others interested in the preservation of antiquities in Great Britain. It marks an epoch in the history of British archæology. The inspectorship had been vacant since the death of General Pitt-Rivers in 1900, while the Ancient Monuments Acts, of which the first was passed in 1882, had long been virtually a dead letter. In 1913, three years after Sir Charles's appointment, a consolidating and amending Act was passed, which much enlarged the powers of the Commissioners, and he was given the standing and title of chief inspector of ancient monuments.

Largely through Sir Charles's activity, notwithstanding the interruption of the Great War, the growth of a public opinion in favour of the preservation of antiquities was fostered and the functions and duties of the Office of Works as the guardian of the nation's interests in its antiquities rendered familiar to a degree which made it possible still further to strengthen the powers of the Department, also recognized in the Town Planning Acts, by the further amending Ancient Monuments Act of 1930. Although Sir Charles retired in 1933, after receiving the honour of knighthood in 1931, he has since then still taken an active part in archæological administration. He continues to be a member of the Advisory Boards on Ancient Monuments of England, Wales, and Scotland, sits on the Royal Commission on Historical Monuments, as well as on the Standing Committee on Museums, and is an elected trustee of the British and the London Museums. In 1933 he was awarded the Royal Gold Medal of the Royal Institute of British Architects.

Dr. A. E. Dunstan

The Council of the Institution of Petroleum Technologists has awarded the Redwood Medal of the Institution to Dr. A. E. Dunstan in recognition of his distinguished services to the science and technology of petroleum. The medal was presented on April 12. Dr. A. E. Dunstan was born at Sheffield in 1878. In 1899 he entered the Royal College of Science, South Kensington. Later on he studied at University College, London, under Ramsay and at East London College under Hewitt. At University College, Dr. Dunstan collaborated with Trouton on investigations into the correlation of physical properties and chemical constitution. He had already published work on viscosity-concentration curves of mixtures. This work was continued at University College and elsewhere, and formed the subject of his thesis in 1910 for the degree of D.Sc. In the meantime, he had communicated numerous papers to the Chemical Society on the problems of viscosity in collaboration with Thole, Wilson, Hunt, Stubbs and others. From 1905 until 1915 Dr. Dunstan was head of the Chemical Department, East Ham Technical College. In 1915 he joined the Anglo-Persian Oil Company. From that time dates the important series of researches on the chemistry and refining of petroleum with which Dr. Dunstan's name is particularly associated. The first important paper relating specifically to the petroleum industry was presented to the Institution in 1916 by Dunstan, Lomax and Thole, and dealt with the pyrogenesis of hydrocarbons. It described the evolution of the process of cracking and of the principles underlying it. A period of intensive research followed on the chemistry of refining processes, during which experimental work was carried out at Abadan and Sunbury. Dr. Dunstan is chief chemist of the Anglo-Iranian Oil Company and a director of National Oil Refineries, Ltd. He was president of the Institution of Petroleum Technologists in 1929–31 and has been honorary editor of the Institution's publications since 1920.

The Magnetic Storm of April 16

The magnetic storm which occurred during the Easter week-end appears to have been one of the most violent ever recorded. Particulars of the disturbance have been supplied to Nature from the Abinger magnetic station of the Royal Observatory, Greenwich, and from Edinburgh. The storm, as recorded at Abinger, considerably exceeded that of January 25 of this year both in range and in intensity. At intervals the photographic traces are difficult to follow on account of the rapidity of change in the earth's magnetic field. Beginning at 5 h. 48 m. U.T. with a sudden sweep of 45′ in declination, the storm almost immediately attained dimensions sufficient to place it among the "great" storms of the past hundred years. Only the salient features are at present available. These may be summarized as follows: The period of most intense activity was from 6 h. to 8 h. U.T. and the storm had virtually ceased by 16½ h. The whole range in the vertical component of the field was approximately 500 γ—not very remarkable except for the short interval of fifteen minutes during which it occurred—between 7 h. 35 m. and 7 h. 50 m. The ranges in declination and horizontal intensity are at present subject to reservation. On account of the rapidity of change some doubt exists as to the identification of the auxiliary traces which are brought into the record in lieu of the displaced ordinary trace when large ranges occur. A tentative estimate of 5° in declination and 2250 γ in horizontal intensity (that is, nearly one eighth of the whole) has been made by the assistant in charge of the Abinger station.

WRITING on April 19, Dr. A. H. R. Goldie, superintendent (Scotland) Meteorological Office, says: "The storm commenced at 5 h. 48 m. G.M.T. on April 16, and from the very disturbed traces of the magnetographs at the observatories of Lerwick and Eskdalemuir the following ranges in the magnetic elements on that day have been measured:

Lerwick Horizontal Force, 2980 γ (1 γ = 10^{-5} c.g.s. units).
Vertical Force, 1386 γ.
Declination, 5° 47′, equivalent to 1450 γ in the component of force perpendicular to the magnetic meridian.
Eskdalemuir Horizontal Force, 1672 γ.
Vertical Force, 1165γ.
Declination, 6° 25′, equivalent to 1850 γ in the component of force perpendicular to the magnetic meridian."

The storm was probably a sequel to the solar disturbance represented by the large sunspot group which crossed the sun's meridian on April 14·1 U.T. (see NATURE, April 16, p. 683).

Aurora Australis on January 22

A COMMUNICATION from the Commonwealth Solar Observatory, Canberra, published on p. 746, refers to an auroral display observed in Australia on January 22, and the solar eruptions and magnetic storms associated with it and with the brilliant display in Europe on January 25–26. Mr. John Gregory, writing from 11 Bennett Street, Perth, Western Australia, describes the aurora of January 22 as seen by him between 8.45 p.m. and 10 p.m. from Busselton, situated on the west coast of Western Australia, a few miles north of latitude 34° S. Throughout the display, short-wave reception from London was perfect and there was little interference in the broadcast from Perth. Referring to the suggestion that auroræ are sometimes accompanied by audible sounds, Mr. Gregory remarks: "I have witnessed many dazzling displays of Aurora Borealis on the Canadian prairies, in the stillness of remote farming areas, but was never able to detect sounds that could confidently be associated with the lights. The slight mysterious crackling sounds one might hear during a display could be heard on almost any cold night, even when the aurora was entirely quiescent."

Curious Effects of Globular Lightning

ON December 6 about 4.30 p.m., a ball of lightning was seen falling at an angle of about 30° to the horizon near Ardglass, Co. Down. It was accompanied by a glare and a loud noise, and on striking the ground there was a burst of flame from the point of impact, followed by a loud explosion. The spot where it fell was examined by Mr. J. A. S. Stendall, of the Belfast Municipal Museum, Miss M. Gafflkin, and Mr. F. Addey, who has kindly supplied all information collected from those who saw the phenomenon. The stem of a hawthorn tree ten inches in diameter had been cut through, and branches had been scattered around, one being thrown 100 yards away from the tree. The bank of a dry ditch had been struck, the point of impact showing clearly from the crushed soil, and fragments of clay were found forty yards away. Excavations were made, as it was believed at first that a meteorite had fallen, but no trace of such could be found at a depth of five feet. At the time of the appearance of the lightning a similar phenomenon was seen at a place six miles away in a north-north-west direction. People described this as accompanied by "a shattering blast which shook the whole countryside". A large crater was found in the mud of a river bank near the scene, but this was quickly covered by the tide and could not be seen when the spot was visited later. The portion covered by the impact could not have been localized to the area of the crater because one person, hearing the explosion, went out and saw sparks jumping off the macadam of the roadway. Mr. Addey suspected a meteorite which had disintegrated, as two balls of globular lightning, separated by six miles, occurring at the same instant, would be rather a rare phenomenon. The fact that a thunderstorm was in progress at the time near Belfast and Lisburn, combined with the fact that there was a partial failure of the electric light in the district, is almost conclusive evidence that the phenomenon was globular lightning.

Tring Museum

THE bequest of the zoological collections at Tring by the late Lord Rothschild is the largest single benefaction both in quantity of specimens and in scientific importance that the British Museum has ever received. The collection may be considered as in two parts, one open to the public and the other reserved for study. In the first section, a general zoological series, are many notable specimens such as the long series of giant tortoises or the superb set of Struthious birds, probably the finest in existence and containing many types. The gorillas and other primates are of equal importance and, in addition, there are specimens of rare or recently extinct animals such as the quagga and fine series of rare marsupials and monotremes. The condition of all these specimens and their taxidermy is of the best. The most important section of the study collections is undoubtedly the enormous series, some two millions, of Lepidoptera. The long series of individual species has yielded, and will continue to yield, much information of scientific value. These Lepidoptera include about six thousand type specimens, a fact which by itself would make this bequest one of outstanding importance to the British Museum. There is likewise an extensive library of zoological, entomological and botanical books comprising about thirty thousand volumes in all. Many of these books are of great rarity. This addition of the Tring Museum will lead, no doubt, to important extensions in the scope of systematic research. Hitherto systematists have too often been hampered by having to work with too short series of specimens. The late Lord Rothschild was alive to this weakness in the founda-

NATURE

SUPPLEMENT

Vol. 141 SATURDAY, APRIL 23, 1938 No. 3573

Social Relations of Science

"SCIENCE and its applications are not only transforming the physical and mental environment of men, but are adding greatly to the complexities of the social, economic and political relations among them". This passage from a resolution of the Council of the American Association for the Advancement of Science, published in NATURE of January 22, is representative of the widespread growth of interest, in recent times, in the social relations of science. The American Association has resolved to take as one of its objectives an examination of the profound effects of science upon society. This resolve seems to have been partly inspired by the movement, started several years ago, to make the British Association the platform in Great Britain for the discussion of social problems which science had helped to create and might help to solve.

Alongside these national movements, international action on the same subject has been taken by the International Council of Scientific Unions (I.C.S.U.). This important body, partly at the instance of the Academy of Sciences of Amsterdam, set up in 1937 a Committee on Science and its Social Relations (C.S.S.R.), as reported in NATURE of April 24 and May 22, 1937 (139, 689, 869). This Committee is charged to survey the influence of science on the world picture as well as on the material side of human life and society; it is to review science and its applications as a whole, and to promote the study of their social influence. Its initial plan is to prepare a report, with bibliographical material, to be presented at the next meeting of the I.C.S.U. in 1940, and thereafter, it is hoped, to be printed for wide circulation.

The collection of data on which the Committee on Science and its Social Relations will base this report is to be obtained from three sources: from national correspondents appointed by national academies or research councils, who will provide information on the national aspects of the social relations of science; from correspondents appointed by international bodies dealing with the several branches of science, who will report from the point of view of their particular sciences; and from individual correspondents having special interest in, or knowledge of, these matters. The appointed correspondents will in many cases find it desirable to enlist the aid of national or international groups of interested men of science, because the field of inquiry, especially for the national correspondents, is too wide to be covered by the knowledge of any single person. It is hoped that by this wide co-operation a report of great interest will be produced, though the difficulties to be faced in compiling it are obviously considerable.

To guide their correspondents in the collection and supply of information, the C.S.S.R. has drawn up a series of fairly detailed questionnaires, one for national correspondents, and others for the several branches of science on which the international scientific unions will report. It is hoped that the consideration and answering of these inquiries will play a useful part in stimulating and clarifying thought in scientific circles all over the world, on the social relations of science; and that the C.S.S.R. will receive from its many correspondents the support without which its efforts cannot but fall short of the great needs and opportunities before it.

The connexion of the C.S.S.R. with such important and established bodies as the International Council of Scientific Unions, the various international scientific unions themselves, and, still more, with the (in most cases) much older national academies, gives it a representative position which could scarcely otherwise be obtained. These connexions in turn impose a duty on the Committee to make its work as scientific in spirit as possible, and in no way to compromise or misrepresent its parent bodies by partisan views or statements. In particular, the C.S.S.R. is not to be, or to be regarded as, a propagandist body; its functions are to survey, to study, to report.

It is excellent that the national academies and international scientific unions should take part in setting up and helping the work of such a body as the C.S.S.R., but the preparation of a condensed report of world-wide scope, to appear two years hence, and perhaps triennially thereafter, is far from sufficient to meet the need within each of the great nations, whose civilization is now largely based on science, for thought, discussion and publication on the social relations of science. Nor does it seem that in Great Britain the provision for such discussion, at the annual meetings of the British Association, is adequate. Further, national scientific academies, such as the Royal Society, probably do well to limit their discussions and publications to the natural sciences, without extending their functions into that great bordering region which the C.S.S.R. is charged to survey. Science itself has its controversies, sometimes keen despite the objectivity of the scientific method and spirit; in that border region beyond, though the like objectivity may be striven after, unity of opinion and agreement in discussion will certainly be more difficult to attain. It would seem best for both sides, therefore, that the arena for the discussion of the social relations of science should be separate from those in which the natural sciences are considered, though many representatives of each should be interested in both.

To be explicit, it has been suggested that in Great Britain (and the same applies to the other great nations) there should be a Society for the Study of the Social Relations of Science (S.R.S.), with a large individual membership, which should not be confined to men of science, though they should play the principal part in it. The Society should have its council, its regular meetings, its publications, and perhaps its committees for the study of selected questions It should receive, read, discuss, and, after consideration by suitable referees, publish papers submitted to it; it might arrange symposia (by the spoken and written word) on special subjects within its range. Its field of work would inevitably trench on questions that have a political importance, but its attitude towards papers submitted to it should be scientific and objective, and it should not in general express corporate opinions, but leave readers to accept or reject the statements in its publications, according to their view of the credit of the authors.

This research method and policy of publication have proved their success in serving science in general, as in the case of the Royal Society, and the many branches of science now organized in separate societies, too numerous to mention, there seems good prospect that a like success would attend the same method and policy applied to this new field. The S.R.S. would be a society for the advancement of knowledge, not a propagandist body for the advancement of science in the public councils and esteem (like the former British Science Guild) or for the advancement of professional scientific interests (like the Association of Scientific Workers). Despite the existence of such useful bodies as Political and Economic Planning and the Engineers' Study Group, which are doing valuable work on the social relations of science, it does not seem that they perform the functions that are suggested for the S.R.S. Questions of overlapping and other difficulties may present themselves, but public scientific opinion on these matters now seems to have reached a stage where the formation of such a society is appropriate.

With the object of obtaining representative opinions upon the subject of social repercussions of science, and the question of promoting their deliberate study by the formation of a new scientific society or otherwise, advance proofs of the above article were sent to a number of scientific workers and others, with a letter inviting the frank expression of their views. The replies received are published in succeeding pages of this Supplement, and are grouped under headings representing in a general way the fields of scientific work in which the correspondents are particularly interested. It will be observed that doubts are expressed as to the need of establishing a new scientific society, and suggestions are made that the desired objects might be obtained through co-operation with existing bodies. Notwithstanding this difference of opinion, it is evidently the decided view of a number of responsible scientific workers that steps should be taken to further the objective study of social relations of science in the hope that the knowledge obtained may make both science and society conscious of their common interests and responsibilities.

Representative Opinions

Sir William Bragg, O.M., K.B.E., P.R.S.

If we assume the truth of the statement at the head of the editorial discussion of the social relations of science, we must conclude that the proposal to form a society for the study of those relations is entirely reasonable ; and the statement is obviously true. The rapid and persistent growth of natural knowledge is something new in the history of the world. Its effects are very great, and there is, as yet, no organized attempt to correlate them. Attention is directed, now here, now there, to some remarkable consequence of the movement, sometimes with pride or gratitude, sometimes in fear. Both pride and fear are often mistaken. There is, in fact, much to be studied, and a society that sets about the task will probably arrive at results that will be interesting, and will be well worth the trouble taken to obtain them.

Sir F. Gowland Hopkins, O.M., F.R.S.

Science workers are often bidden just now to remember the complexities which science and its applications are adding to the world's problems, and to realize that it is their duty to help in shouldering the responsibilities involved. To-day, the situation must be considered no less from another point of view. Science itself is face to face with efforts, unfortunately only too successful, to impose on nations an artificial social structure of a kind which is definitely antagonistic to the progress of science, and in the long run, as history suggests, may even lead to its arrest.

I have often wondered, when laboratory workers, as such, are asked to take action, what precisely they can do beyond performing their duties as good citizens. It is clear that individuals can do little, and that experimental scientific workers immersed in research are ill qualified, when unaided, to take effective action of any kind. If solutions are to be found, the problems call for close study and careful analysis, and I venture to think that the effect of totalitarian policy upon scientific output should be continuously scrutinized and brought to notice.

It would seem that such tasks could be well undertaken by a society such as that proposed. It must, of course, establish international relations, and I think it would need the help of an information bureau. Its membership must certainly not be confined to the working men of science

Sociology and Economics

H. G. Wells

The essential difficulty in working out any special social functions for scientific men lies in the fact that, so far as the great majority of sciences go, the individual worker has no special aptitude for social organization. His time, his mental energy he owes to his special work. But this is less true of certain sciences than of others. It is less true, for example, of biology than of astronomy. It is less true of anthropology and psychology than of invertebrate anatomy. In the case of human ecology and social psychology, the man of science works in a field whose generalizations are almost immediately applicable to social organization. Every science insists upon integrity, explicitness and devotion to the extent of entire disinterestedness, and so the study and teaching of any science tends to brace the character and sweeten the social atmosphere. But it is through the pushing of the boundaries of science out into that field of rash generalizations and mischievous traditions known as human history, that the practical hope of mankind in science lies.

The S.R.S. claims the attention and frank criticism of every type of scientific mind, but if it is to operate efficiently it will have to create opportunities and support for an increasing number of social biologists and social psychologists. There is little advantage to be found in the distinguished experimentalist in physical science dissipating his time and genius in amateurish contributions to political and social theory. There is everything to be gained by a S.R.S. that will keep him in touch and co-operation with social scientific work and thought as intensive as his own.

Prof. John L. Myres, O.B.E., F.B.A.

Is the proposed Society for the Study of the Social Relations of Science to be yet another 'learned' society, or something else ?

In the natural sciences, physical and biological alike, there is no limit to the applicability of discoveries to human ends, economic and social, "transforming the physical and mental environment of men". Such applications are the concern primarily of individuals competent to supply admitted needs of their fellows, and eager to stimulate fresh needs ; next, of specific associations for the promotion of such enterprises, in medicine, engineering, various industries, and the like ; and ultimately of the citizens at large, and their organs of administration and policy, competent to use, abuse, or disuse. Philosopher-kings and totalitarian dictators presumably provide for inclusive survey of all applied science 'in the interest of the governed'. Like the centurion, they "say unto this man 'go' and he goeth" ; unlike him they are not "under authority" and nothing printed in Nature need affect their doings. In a 'free' country, what form does "King Solomon's House" assume ?

Clearly 'social relations' are not the business of the 'learned' societies. The less these are concerned with 'practical applications' or with practical restrictions, the better. For all these involve judgments of values—considerations political or moral, not scientific at all.

I have the same uneasiness about 'applied anthropology' as about 'applied' genetics, when undertaken by a 'learned' society; for 'learning' and life are fundamentally different. From the dentist to the destroyer, we all 'apply' gas. Some also 'apply' prayer, to avert pain and war. But these 'applications' concern neither chemists nor theologians.

Though the Committee on Science and its Social Relations is "charged" by the International Council of Scientific Unions, one of the greatest of 'learned' societies, and is, as stated, "not to be, or to be regarded as, a propagandist body", it is nevertheless expected to "play a useful part in stimulating and clarifying thought"; there are "great needs and opportunities before it"; and it is concerned (among other matters) with the "national aspects" of the social relations of science, which differ notoriously between one nation and another. But this is politics, not science.

The British Association, in addition to the "promotion of scientific enquiry" and of "intercourse between those who cultivate science", has among its objects "the removal of any disadvantages of a public kind which might impede its progress", and has often attempted this, and still oftener been urged to attempt it. But these functions are concurrent and distinct.

So too these current inquiries of the American Association are concerned with the "complexities of the social, economic, and political relations" among men, and are distinct from its function of discovery.

Is the proposed Society for the Study of the Social Relations of Science designed to be yet another 'learned' society, duplicating or supplementing the activities of the C.S.S.R. and the American Association? It "would be a society for the advancement of knowledge, not a propagandist body" like the British Science Guild or the Association of Scientific Workers. But also "it would inevitably trench on questions that have a political interest and importance", like the British and the American Associations. Its promoters should make up their minds whether it is to be a historical, or a philanthropic society; a society for the Study of Spilt Milk, or for Promoting the Good Will among the Stronger.

Prof. H. J. Fleure, F.R.S.

THE development of machinery has made productive capacity enormous and thus accentuated rivalries, while the increase of modern communications has made national frontiers a source of increased irritation, and the jostling of peoples has inspired fear for the future of cherished national traditions. Sources of machine-power, again, have changed, and some who look into the future are inclined to picture a world largely dependent on power-alcohol from cellulose, which means that relations of Europe to the warm lands will enter a new and difficult phase.

In other directions also, science is having far-reaching effects on thought. The idea of evolution working itself out in comparative religion and in psychology is beginning to have revolutionary influences on ethics and beliefs, effects as yet only dimly perceived by many leaders of religious organizations. Again, the accumulation of knowledge concerning ancient and modern China, India, Mesopotamia, Iran, Egypt, and so on, is altering into a sort of glorified provincialism the old habit of starting an argument concerning society with examples from classical Greece and leading on through Roman, medieval, renaissance and later periods. We are in the throes of as deep a change of both economy and thought as that which included the breakdown of the medieval church in north-western Europe and the voyages of discovery. Old bases of conduct, sources of social motive power, visions of the world, are changing, and there is a natural recrudescence of authoritarian ideas as a fear-insurance against chaos, or against the triumph of an equally authoritarian rival.

The change is in the main the effect of the impact of science, of the vision of truth as something to be sought, of the consequent view that all beliefs are provisional and that neither reason nor emotion gives us final conclusions. It therefore seems that scientific workers owe it to the community to see that they study the social relations of science. A recent election of a student of physiology as a professor of philosophy is a welcome indication of awareness of the change in thought that is beginning. If necessary, we must found a new society to study these matters, however difficult it may be to ensure reasonably unprejudiced discussion.

Might we not, however, try to encourage existing societies that study mankind in the broadest way to occupy the field? Anthropological and folk-lore societies, in co-operation with sociologists, historians and geographers, should realize increasingly that our own social life is material for study just as much as is that of distant peoples of the present and past. The influence of science on production, transport, population and its distribution, social motive power, and the springs of conduct and belief can all be considered as within the anthropological field, wherein have long worked many who know a great deal about lowly peoples and ancient society, and so can help us to know the rock whence we were hewn and the manner of the hewing. A conference of workers interested in the problem of the social relations of science is clearly called for, together with a consideration of the difficulties arising in our universities from the old division into faculties of arts and of science, which is becoming a hindrance and was never more than a practical convenience.

Prof. P. Sargant Florence

IT is often said that economists are blind to the impact of science upon society and that they are neglecting the changes that have come over industrial organization as a result of scientific invention. This may be true of the school of economists who argue from traditional assumptions carried over from an age when science *was* negligible. But it is impossible for any realistic economist trying to generalize from actual events to ignore the consequences of scientific progress. In my presidential address to Section F of the British Association last year, for example, I directed attention to the increase in the number of men per factory and to typical differences in the number of men per factory as between different industries. This general increase and this differentiation both appear to be correlated with technical factors, particularly the growth of mechanization. Mechanization measured by horse-power and overhead costs per man has increased generally, and in those industries where mechanization is greatest the number per factory tend to be greatest. The higher the mechanization of an industry, the larger is the size of its constituent parts.

Scientific invention has led to more machinery being installed. More machinery has led to more men being employed in one organization. In its turn this large grouping of men is leading to the invention of new sorts of social organization. More capital is needed to buy the machines; joint stock companies are formed to pool capital. The control of larger and larger groupings of machines, men and capital becomes increasingly difficult for the joint-stock shareholders, and the power over each company is put into the hands of boards of directors usually representing a minority of investors. The companies themselves become too small as units of control, and methods of concentrating control are devised such as interlocking directorates and holding companies.

By the time this stage has been reached, economic organization has become the concern of society as a whole. Consumers are faced with the possibility of monopolistic exploitation. Citizens are faced with dictatorship by high finance. In this pass, to study the social relations of science is the least society can do! The impact of science, though working indirectly through the economic mechanism, may well be overwhelming in its ultimate effect. Certainly we must be prepared, by the formation of such a society as the proposed S.R.S., to measure the force and direction of the impact. And I venture to think that the economic mechanism, such as I have outlined, through which science affects society, must be investigated particularly closely. For this a certain professional training in economics and the social sciences seems to me essential—a student of natural science cannot leap at it by the mere light of Nature! May I suggest, therefore, that an early task of the proposed S.R.S. be to find means for professional training in realistic methods of economic and social research?

Prof. H. A. Marquand

I AM enthusiastically in favour of the establishment of a Society for the Study of the Social Relations of Science. Students of social problems are often, like myself, childishly ignorant of the natural sciences. On the other hand, I have often heard very competent men of science utter childish opinions about social and economic questions of the day.

The need for co-operation and closer contact between the two branches of study has been admirably expounded in NATURE. I would only add that if the new society is formed, it should confine itself to persons fully qualified in the fields of study it hopes to unite. An immense amount of valuable time will be wasted if the numerous quacks, well-intentioned but untrained, who pose as authorities on economic and sociological questions are admitted.

The task before the new society is urgent; and it should not allow itself to be diverted from profitable lines of research by a sentimental desire to be 'fair' to all 'points of view'. Economists, in particular, will be quite prepared to recognize the authority of a duly appointed university teacher or fully qualified research worker in his own field of science. Let the men of science seek the co-operation—at least at first—only of persons similarly qualified in economics. It will be found that there is a large amount of agreement among them on fundamentals of analysis.

At a later stage, the findings of the society can be presented with real authority to the public. The public itself can then make its choice between the alternatives available—for there always will be alternatives in social policy. What the society can do is to ensure that the alternatives are thoroughly understood and that as many as possible of the data required to ensue the choice are scientifically prepared by fully competent persons.

Prof. Harold J. Laski

I THINK the idea of such a society as is suggested may prove of real value; few things are more important at the present time than the interchange of views between men of science and those who are concerned with the study of social phenomena. Their past separation has been a grave misfortune since (*a*) it has led to the neglect by scientific workers of the several implications of their own work, and (*b*) an inadequate knowledge by statesmen and by professional students of several organizations of the implications of scientific discovery. A body that might help in breaking down the existing barriers is, at least potentially, one that has important work to do.

It is, however, important, I think, to emphasize that such a society must occupy itself as well with ends and values as with the description of phenomena. Work like that of Sir John Orr has implications which go out into the realm of action; it emphasizes the need for scientific workers to give, as it were, the laboratory to life. The man of science is also a citizen. He has the responsibility of seeing that the conclusions he reaches are related to the purposes our social order is seeking to fulfil.

Prof. Morris Ginsberg

I SYMPATHIZE very strongly with the proposal to establish a society for the study of the social relations of science. I should, however, like to make a comment from the point of view of sociology. It is, it seems to me, very important that society itself should be studied scientifically, if the effects upon it of the achievements of the natural sciences are to be correctly interpreted. On one hand, science is itself a social product, and its evolution is shaped at least in part by social and economic forces, and these are matters for sociological inquiry. On the other hand—and this is in relation to the present proposal more important—the study of the effects of science on social relations requires not only a knowledge of science, but also of social relations.

Now, though in fundamentals the methods of science are the same whatever may be the field of inquiry, it is not be be assumed that the technique of the natural sciences can be applied forthwith to the field of social relations. The history of social thought offers abundant illustration, of which the most striking, perhaps, is the hypothesis of natural selection, of the disastrous consequences that have resulted from the application of scientific theories to social problems without direct examination of the sociological data.

If, therefore, as I hope, the society is established, I think that one of its functions should be to encourage the direct study of social facts, and that on its councils sociology should be adequately represented.

Alexander Farquharson

THE proposal for the development of new means for the study and discussion of the social relations of science will have, I am assured, widespread support among sociologists. To these, the subject is not new. Much thought has already been given to the social origins of science and to its social effects. It is, however, undeniable that a systematic and co-operative effort to examine these and similar problems would have fruitful results. In such an effort, students of both natural science and of sociology should take a full share. I hope that some historians of culture and some philosophers with a social outlook may also be ready to take part. It may, however, be suggested that use should be made both of the observational method of the scientific worker and the methods used by the historian and the social student in the study, through documentary evidence of past and present.

Psychology

Prof. C. Spearman, F.R.S.

AMONG the sciences at issue an important place can scarcely be denied to that of the mind. Indeed, seeing that this is a field which covers all knowing, feeling and doing, a plausible case might be made out for crediting this mental science with ruling everything in the world that possesses value as an end, and not merely—like the material sciences—as a means. In special degree, surely, this holds with regard to social values. In good enough accord with this *a priori* staked-out claim of psychology, we find in actual fact a more universal appeal to it for aid.

First of all the appellants came education. Not far behind was mental pathology. Later, but trying hard to make up for lost time, have been the calls to assist industry. Still more modern is the acute realization of the psychological basis of criminology. Last of all, perhaps, has been a lively call to solve the problems of polemology (*sit venia verbo*).

On the other hand, however, there are not a few sceptics who would make out that the promises of psychology are greater than its performances. Unfortunately, this charge does appear to have not a little foundation. Nevertheless, it can certainly be exaggerated. In many cases the social achievements of mental science stand out far beyond the reach of all legitimate cavil. Take, for example, the new developments of knowledge about individual mental differences. At the most conservative estimate, this knowledge would appear to be fundamental for all social organization and endeavour; from, say, confiding in M.P.s to sterilizing the unfit.

Here we arrive at one last critical point. Let us grant that mental, at least as much as material, science has vital relations to society. We have still to inquire why these relations should be thought to need special treatment, by committees, associations, and so forth. May not rather the relations be taken as already treated in an adequate manner by the two studies thus related, psychology and sociology ?

The answer would seem to be decidedly in the negative. Here, as in so many other branches of science, the application of one to another is apt to be a very delicate and difficult operation. A notorious illustration is furnished by the frequent complaint of physiologists, that they urgently need the aid of chemistry, but not such as is currently supplied by chemists. In their turn, psychologists stand in a very similar relation to physiologists. So likewise, it would seem, do sociologists to psychologists.

By all manner of means, then, let us get together. The whole situation, after all, is but an instance of the old saying that sciences grow where they meet. Accordingly the advent of the S.R.S. would seem to deserve a cordial welcome.

Prof. J. C. Flugel

THERE can, I think, be little doubt that a society such as is contemplated could perform a very useful function, a function indeed which, before long, we may come to look upon as indispensable. I imagine, however, that to fulfil this function properly the membership will have to be drawn in about equal proportions from scientific workers proper and from men engaged in the practical tasks of organization and administration in the most diverse spheres, not excluding that of politics.

As regards its individual members, the society will have a double task. On one hand it will foster the increasing sense of responsibility which scientific workers are beginning to feel for the social consequences of their discoveries : while in the executants it should cultivate a corresponding ideal for the full and proper use of science and—what is even more important—for the adoption of a scientific attitude in those fields, for example, of politics and economics, where traditional or emotional bias is only too apt to interfere with a calm and impartial investigation of relevant facts.

Society to-day is based on science, and it is becoming recognized that the social problems created by science can only be solved by yet further extensions and applications of scientific method. Those who make scientific discoveries and those who apply—or misapply—them should be looked upon as members of a team with a joint responsibility to the human race at large. The better the understanding between them and the closer their co-operation, the better it will be for them and for society. The man of affairs can suggest innumerable problems to the man of science, many of which can be dealt with by well-known existing scientific methods, while others will probably stimulate research in new and profitable directions. The man of science, on his part, will be helped to realize how much of human life is still muddled and unscientific, still awaiting the illumination which only science can bring. The co-operation of the two types of men in a single powerful body may eventually help to bring about a vast extension of the scientific field—with, of course, a corresponding increase in the number and influence of scientific workers themselves.

The society, I take it, will be no mere paper-reading association, though the interchange of views at meetings will be an essential task. It will also, as I envisage it, become, at least eventually, a consultative body to which politicians, social administrators and industrialists will naturally turn for help and information, and to which men of science also will apply for assistance in obtaining such social facilities as they may need for their work (and in the case of the human sciences such facilities may be of great importance).

As the work of the society proceeds, the establishment of special advisory committees—temporary or permanent—will probably be necessary, and in this connexion the society will possibly co-operate with, or incorporate, certain smaller and more specialist bodies already in existence. The main function of the society will, I take it, not be propagandist: nevertheless, it might undertake a certain amount of directly educational work in certain fields where a wider popular appreciation of scientific findings appears to be particularly urgent.

In founding the society, care will have to be taken not to define its constitution or functions with too rigid a precision: so that full advantage may be taken of that most precious characteristic of British institutions—their ability to evolve as circumstance or necessity requires.

Dr. Charles S. Myers, C.B.E., F.R.S.

In these days no one will welcome the formation of a new society unless it can be shown to serve a new and important purpose. But a Society for the Study of the Social Relations of Science does seem to meet a new need. If its council include representatives of the chief existing societies which are already concerned essentially with social affairs (for example, those bodies dealing with public health, applied psychology, ethnology, sociology, etc.), the S.R.S. will constitute a new body which will for the first time bring together in mutual sympathy and co-operation all interested in the various social implications of such 'human' sciences. But by the present proposal its sphere will be enormously widened, and become correspondingly more valuable by the inclusion of the 'purer' sciences of physics, chemistry, and biology, together with their applied aspects of engineering, pharmacology, etc.

This new society will not only encourage in research workers a fuller recognition of the actual and possible social implications of their work. Its activities will also impress on the general public the important social bearings of the physical and biological (including the 'human') branches of natural science, and will increase the national support of scientific research. I hope, therefore, that the S.R.S. will come into being, and I believe that it will serve a valuable scientific and social purpose.

Prof. F. C. Bartlett, F.R.S.

I should like wholeheartedly to support the proposal for the formation of a Society for the Study of the Social Relations of Science. Everybody now agrees that the impact of almost all branches of science upon social life is intense, and that the problems which arise as a result of this impact have a significance for the future of civilization, both national and international, which can scarcely be exaggerated. Most thinking people are coming to realize also that these problems are as amenable as any others to scientific study and direction.

There is at present no adequately constituted body which can co-ordinate the many sectional and specialized interests which are being attracted to a study of the social implications of particular branches of science; but without such co-ordination development is bound to be not only tardy, but also ill-balanced. I also agree completely with the view that the primary need at present is for the formation of a number of properly constituted national scientific groups for the study of the social relationships of science. The problems involved are so complex, so influenced by the established culture of differently organized national groups, that an international body alone cannot hope to cope with them, in the first instance with much promise of success.

I believe that the time is fully ripe, in Great Britain, for the establishment of a society with the constitution and aims described, and that such a body would perform a service of value for the nation, and ultimately for mankind.

Biology

Prof. A. V. Hill, O.B.E., F.R.S.

A notable example of the need to study the social relations of science is in the matter of public health. If guided scientifically, the present general interest in 'national fitness' may be the beginning of an altogether new outlook on human biology, destined to place the maintenance of health and the development of normal human faculties, as equal partners with medicine, in the place reserved at present for the treatment of disease. The scientific knowledge is already largely available: the social applications of it require public action which scientific workers alone cannot take, but in which they must be the guides of public opinion if the action taken is to be wise and effective. This is an international as much as a national problem, and one in which all kinds of co-operation, political, economic, moral, as well as scientific, are needed.

The obligations of scientific people in the matter of national defence will doubtless be referred to by others. Warfare, unfortunately, is not out of date, and it is certain that in the present state of the world its methods will be largely based on science. A free country in which the best scientific men were unwilling—from whatever motives—to co-operate in defence, would suffer from the grave disadvantage of having to employ the second best. Science in the free countries must be willing to play its part, or they may cease to be free: and—apart from anything else—if no freedom be left science will be deprived of its chief instrument, frank and open criticism. Already in countries which are not free it is difficult (at least for the non-expert) to discern what is truth and what is propaganda.

One of the problems certainly of the proposed society would be that of the use—or misuse—of scientific research and knowledge for purposes of war: but this problem is only part of a much larger one, that of the use of the common property of scientific knowledge for selfish purposes. The ethics of secrecy in research, of patenting discoveries of value to the public, of advertisement, of 'expert evidence', of permitting scientific quackery, of exploiting dangerous knowledge or selling dangerous drugs—all such matters are parts of the same problem, not always easy to solve: as indeed is that of using a reputation gained by scientific work, or reflected from the main body of scientific workers, for any sectional or selfish purpose. Medicine for thousands of years has had its standards of ethical behaviour, sometimes abused no doubt, but on the whole an enormous safeguard to the public and to medical men alike. Science needs similar acceptable standards, and one of the chief functions of the new society might be to consider the general question of scientific ethics.

Prof. John S. B. Stopford, F.R.S.

THE effects of the applications of science upon social relations are evident to all, and few will dispute the urgent need for the dispassionate study of the perplexing problems which have arisen. The present facilities for discussion of these problems and the provision for publication are clearly inadequate, and it would be disastrous to charge the national scientific academies with this work, although scientific workers cannot divest themselves, as individuals and citizens, of a responsibility. It would appear inevitable that the task can only be undertaken by such a new society as the one suggested.

The great difficulties appear to arise at that point, and some of the more important safeguards are stated in the preliminary editorial. The matter which the society will have to survey, study and report upon, is of such a nature that it will not always be easy to avoid propaganda and bias, and yet its success will depend to a large extent upon the most strict avoidance of even a suspicion of the intrusion of such things.

One doubt in my mind is whether a Society for the Study of the Social Relations of Science can not only adopt, but also maintain, the method and policy which has proved so successful in the case of the various scientific societies. The new field to be studied is so different that this question seems initially to be the vital one. Another doubt concerns the composition of the contemplated society. It seems doubtful whether men of science ought to take quite such a principal part as is suggested. The consequences of science are so varied and of such a kind that it is most important that the society should have the full benefit of the advice of many others competent to bring knowledge which does not fall within the experience of the scientific worker.

These and others are matters which of necessity will demand much thought, but I earnestly hope that serious consideration will be given to the proposal for the formation of a Society for the Study of the Social Relations of Science.

Prof. J. B. S. Haldane, F.R.S.

IT is obviously desirable that the social relations of science should be studied. But it is equally clear that such a study presents formidable difficulties, and I question whether, even though it does not express corporate opinions, the attitude of the proposed S.R.S. towards papers submitted to it will always succeed in being scientific and objective.

The choice of papers is to depend on "suitable referees". I do not envy them their task. They will have to avoid, on one hand partisanship, and on the other the temptation of rejecting communications voicing 'extreme' opinions merely because such opinions will be offensive to some readers or hearers.

I trust that one condition will be rigidly enforced. Membership should be individual, and no scientific society should be asked to nominate delegates. For example, the Genetical Society includes on its council members with very various opinions concerning eugenics and racial purity. If it were asked to nominate a delegate to the S.R.S., it would be inevitable that these opinions, as well as scientific achievement, would be considered in elections to its council, and a formidable blow would be struck at the society's scientific integrity.

But if this and other safeguards are carefully, and even pedantically, enforced, the S.R.S. may play a valuable part in bringing to light the relations between science and other social activities. I trust that the word "science" will not be too narrowly interpreted, and that anthropologists will be encouraged to discuss the development of technique in primitive societies and its impact on social structure and function. Only against such a background are we likely to view contemporary problems with any approach to objectivity. For the same reason, it is vital that the society should include members not merely engaged in the directive side of industry, but also in manual work. For it is clear that one of the main social consequences of scientific progress has been to alter the functions and status of manual workers.

If these and other conditions making for objectivity are fulfilled, I believe that the S.R.S. can perform a most valuable function. But if not, it may easily become a propagandist body, either for some particular theory, or more probably for the preservation, with trifling modifications, of our existing social system.

Sir Peter Chalmers Mitchell, C.B.E., F.R.S.

MY difficulty about the proposed new society is that the social relations of science cannot be studied in a scientific vacuum, but must be in an atmosphere daily becoming more inflamed by the opposition between the two views of society which, using the terms in the broadest sense, may be called the capitalistic and the socialistic. For example, the sudden discovery of a large-scale method of synthesizing starch or sugar might, and probably would, produce a panic in a capitalistic State, and be a welcome boon in a Marxian organization. But the new society certainly would be interesting, and would be rocked with dissension in exact proportion to the intellectual integrity of its members.

Prof. W. E. Le Gros Clark, F.R.S.

NEW developments in the history of science are only rarely due to the discovery of facts hitherto unknown or to the elucidation of new principles—more often they are the result of a conscious realization, sometimes quite abrupt, of relations and perspectives which have previously been unconsciously accepted or only dimly recognized in the background. But the general background must ultimately be taken into account in judging the implications of any line of scientific development, even though attention tends at first to be concentrated on the separate and more conspicuous details which are the immediate interest of the laboratory worker.

The social background has always been present in the history of science, playing an important part in directing the inquiries of the man of science along specific lines, and being itself also influenced by the results of his discoveries. It is possible now to look back and see quite clearly these interactions, of which the scientific workers of the time were themselves completely unaware. The conscious realization of the social relations of science, indeed, has only recently been generally acquired.

This has more than a theoretical interest, for it marks the first step towards their ultimate control. Herein many see an inspiration for the future. It is one of the achievements of modern psychiatry to have demonstrated that a mental attitude can only be adequately controlled when the individual becomes fully conscious of all the factors by which it is determined. This thesis is equally applicable to external situations. Consequently, having become aware that the social relations of science are really potent as an influence both on the development of science itself, and also on social evolution, it is now urgently necessary to develop as completely as possible our conscious appreciation of the processes underlying this reciprocal action.

This can only be achieved by an extensive analysis of the effects of the progress of scientific discovery on human society, and of social developments on scientific progress, in the past and present, with the object of determining precisely how these effects are brought about. The results of such an inquiry must be formulated with complete objectivity in order to provide a truly scientific foundation for the adequate control of the same processes in the future. That such control is, to say the least, highly desirable, will become more and more apparent as the inquiry proceeds.

Those exponents of social systems who are most eager to belittle the claims of science for representation in directing the destiny of mankind are precisely those who are making the fullest use of the achievements of the scientific worker in the pursuance of their own interests. The misapplication of scientific discovery in the promotion of social evils, no less than its justifiable employment for the true benefit of humanity, requires to be clearly and objectively expressed, as a necessary preliminary to securing proper recognition of the status of science in the social order. The proposal for the institution of a Society for the Study of the Social Relations of Science could scarcely come at a more appropriate moment, for such a society would provide the obvious mechanism for initiating the first step by scientific workers as a body in an attempt to carry out this ideal.

Prof. J. Graham Kerr, M.P., F.R.S.

I AM naturally much interested in the proposal to found in Great Britain a Society for the Study of the Social Relations of Science. The special relation to which I have endeavoured on many occasions during the last twenty years to direct attention is the application of science to the training of the citizen. The system of education as we know it to-day is the system that has come down to us from medieval times. Designed in those days for the training of the priesthood, and extending secondarily to the upper classes of the community, it was this system of training—in the main literary and cultural—that naturally became the system of education for the ordinary citizen, as the development of the art of printing made possible its diffusion through the community. Modern developments in education have been, in the main, improvements in technique, which have left its general framework untouched.

I had the advantage in my early days of acquiring intimate personal knowledge of a comparatively primitive race of men still in the nomadic hunting phases of communal evolution, and it was of extraordinary interest to compare their system of education with that of our Western civilization. With them the end aimed at and reached was fitness—bodily, mental and moral—to play their proper part as members of the community. Hard exercise and plain, sparse diet developed a hard, lean body of A1 quality. Games simulating war and the chase developed the senses to the highest pitch of acuity, and the mind to draw rapidly and correctly the proper conclusions from what was observed. Instruction by the grown-up members of the tribe instilled into the youthful mind the hard code of tribal ethics and discipline, infringement of which brought severe punishment.

What will, to my mind, be one of the most urgent tasks before the S.R.S. will be to tackle the problem of how we are to get the training of our citizens back to a system in which mere superficial culture is brought into proper proportion with, on one hand, such branches of intellectual training as skill in observation and in the thinking out of the correct conclusions, and, on the other hand, the development of physical fitness and moral discipline.

In this strange new world which has evolved during the past century or so—a world in which ideas, good or evil, are swiftly diffused through the community by printing, wireless, the cinema; in which security from pestilence is dependent entirely upon the advances of medical science; in which the very food supply depends upon the applications of science—in this strange new world the call is urgent for such an investigation of the social relations of science as is suggested, if indeed our civilization is to be saved.

Prof. J. A. Ryle

THE medical sciences, above all others, should keep continually in view their responsibilities in connexion with the maintenance of social relationships. Never before has the ground been so abundantly prepared for fruitful contributions on their part to social reorganization and human betterment. The 'time-lag' between discovery and application is often disturbing. This and the modern acceleration of discovery have made it necessary to envisage more effective measures for ensuring free intercourse between the scientific workers and the legislative councils of a country. A Society for the Study of the Social Relations of Science could clearly give valuable help in this direction.

In the preventive field of medicine particularly, requisite data for new and effective reforms are constantly coming to hand. In the matter of control of infection in its epidemic forms, most civilized States are already well advised. There remain, however, other sources of serious infection in the community, as in the case of the milk-borne diseases, which are now known to include the typhoid fevers, brucella abortus infections, and certain grave streptococcal diseases. For the mode of origin and transference of these, science has provided the evidence, and for their prevention the necessary instructions. With healthier and tested herds and compulsory pasteurization and bottling of milk a vast amount of sick-wastage and many hundreds of lives could be saved in Great Britain every year by means of legislation which should not present grave difficulties or inflict any commensurate hardship or alternative risks.

Much could be done to further the recognition and control of droplet infections. In institutions such as schools, hospitals, barracks and offices, these are responsible for a large and continuous sick-wastage and a high incidence of serious diseases, including scarlet fever, pneumonia, meningitis, septicæmia and otitis media. Spacing of beds, better ventilation and measures permitting earlier segregation of infected persons might call for heavy initial expenditure, but the eventual saving of time and labour, health and life, would make ample repayments.

Recent nutritional research has shown that, apart altogether from rickets (now becoming rare in its florid form in civilized States) and scurvy, beriberi, and pellagra (which are largely confined to poverty-stricken zones and native populations), there is in every country much widespread chronic ill-health and inefficiency directly attributable to subnormal diets. The growth and health of children in poor industrial areas and in the homes of many agricultural labourers are still seriously handicapped by protein and vitamin deficiencies, and under the same conditions young mothers frequently suffer from serious mineral deficiencies, especially in respect of iron. The evidence for this has been fully substantiated by social and dietary surveys on one hand, and by clinical and nutritional research on the other.

That such conditions should exist in a wealthy country suggests not only that the organization of society itself must become an even more urgent concern of the sociologists and politicians, but also that there are at present too many obstacles to the transmission of knowledge from the scientific workers to the legislature and to the community at large. In the genetic field knowledge has sufficiently advanced (given the assistance of better education both for the doctors and the public) to make practical measures both of positive and negative eugenics feasible, and this without any interference with the rights and liberties of the individual.

In brief, a more concerted attack upon all the diseases and disabilities, with their attendant loss of time and labour, which are attributable to endemic infections, malnutrition, inadequate light, air and exercise, and uncontrolled and uninstructed breeding, is overdue, and there can be no contradiction of the scientific evidence which declares it to be so.

Any organization which may assist the study of the social relations of the biological sciences and encourage the better application of new knowledge will be likely to receive the warm support of medical men in whatever branch of practice, education or research their work may lie.

Prof. F. A. E. Crew

NOTHING is more desirable—even necessary—in my opinion, than that some organization, with the structure and the functions of the suggested S.R.S., should at once be brought into being. Nothing could be more urgent, more opportune. But, for a number of reasons, I should like to see it grow into a section of the British Association, which I sometimes think now requires a fresh purpose.

It is generally accepted that the world we live in has been re-shaped by science; that our social structure is utterly dependent upon the creations that science has made possible; that there is no longer any question of a return to the domination of Nature; and that man must strive for the complete mastery over his environment, and must secure the power to control his own further evolution.

Scientific workers are enrolled in great numbers in the service of the community, for the reason that those who are in charge of our social evolution are persuaded that only through the further and more intensive application of science to human affairs can we hope to solve the many and complex problems of society. Those who work at the forge of some specialism in science are commonly aware of the possibilities concerning the use of the tools that they are fashioning, and are distressed when these are used not at all or else are employed unintelligently for unworthy purposes. While it is not to be expected that they themselves should be able to construct sound policies relating to human and social betterment, since in them thought is inclined to run in narrow grooves, and the treatment of the rest of life's interests tends to be somewhat superficial, yet from them and from them alone can come certain kinds of information of the greatest possible value, strong threads of ascertained knowledge which can be woven into the social fabric by such as there may be whose minds do not lack balance.

On the other hand, there is an educated public, keenly and anxiously aware of the quality and the promise of the contributions that science is making, eager for further information and understanding, and seriously interested in matters of government. The suggested S.R.S. could provide a meeting place for those men of science who gladly accept the view that science is an instrument which society is using for its own purposes, and for those who are interested in, or concerned with, statecraft, acknowledging that it is to science that we must look for any lasting contribution to the permanent advancement of man's well-being.

The hope of the future, I think, lies in the fact that the biological sciences have grown so large and needs must grow larger. In them is to be encountered knowledge that, intelligently used, will certainly remodel mankind and re-fashion society. But for the present these are largely neglected, for science is now encouraged mainly for economic reasons, and its fruits are used almost exclusively for economic ends. The S.R.S. would be serving a most useful purpose if it could act as an amplifier for the voice of the humanist, for nowadays this is drowned in the ceaseless noises of calculating men and machines.

Prof. E. J. Salisbury, F.R.S.

Any addition to the numerous societies that already exist would need ample justification; nevertheless it cannot be doubted that the contacts which scientific advance makes with the broader aspects of human affairs are often entirely neglected, despite their manifest importance. For example, though the social study of plants is by no means a new one, the importance of our knowledge of plant communities in relation to such matters as erosion and water supply is only just beginning to be recognized. The findings of the ecologist and plant physiologist have their significance for the student of amenities no less than for those concerned with the conservation of a shore-line or the maintenance of a national park. The dynamic character of communities of plants and animals, the changing nature of their balance of life, have important practical implications which are not only neglected but also often unrealized.

Here, indeed, as elsewhere, the gathering momentum of increasing specialization has its grave dangers unless accompanied by a correspondingly augmented synthesis of knowledge. The fostering of a balanced mental nutrition is perhaps the most important function which the universities should to-day perform, for they almost alone are the guardians of this synthesis of thought between one and another branch of pure knowledge. But there is no continually functioning body the special concern of which is to develop and maintain the cross-currents of knowledge in all their wider applications to human affairs. It may be justifiably asked whether there is not a real need for some body the main function of which would be to focus attention on the social implications of advances in science and, whilst meticulously avoiding any propagandist or political bias, would educate public opinion in these respects.

Dr. J. S. Huxley, F.R.S.

I am sure that the establishment of a Society for the Study of the Social Relations of Science would be of great value. At the moment, there is no common meeting ground for those interested in such problems, and the result is a scattering of aim and a lack of agreement as to method. As a matter of detail, it may be suggested that the meetings of such a society should not always be held in the same spot, but at different places, and perhaps often in conjunction with the meetings of other societies. One meeting each year might be held in relation to the British Association.

Just as the Royal Society has many other functions beyond that of meeting for the reading of papers and the holding of discussions, so this new society should from the outset contemplate a fuller scope. For example, we are at the moment without any accurate knowledge on many basic facts concerning the social relations of science. What research is actually being done in Great Britain, under what conditions, and how financed? Why are some branches of research relatively neglected? What are the observable trends in the nature of research, and what can be said as to its practical results and social effects?

Numerous questions also arise concerning such matters as the organization of scientific publication and abstracting services, and what might be called the 'public relations' aspect of science.

It would seem, therefore, as if such a society should aim (*a*) at having money for research grants at its disposal, (*b*) at the organization of an information bureau analogous to the Imperial bureaux already established for pure and applied sciences.

Dr. Joseph Needham

There can be no doubt that the proposal to set up an organization for the study of the social relations of science will be welcomed by wide circles of people, not only in science, but also in industry and all departments of public life. For such a step the time is more than ripe.

The 'ethical neutrality' which has often, no doubt rightly, been described by philosophers as part of the scientific method, has sometimes been interpreted as meaning that it is the duty of the scientific worker to hold no views, and entertain no hopes, about the social order in which his work is done. If the scientific worker were exempted from paying income tax and enjoyed neither municipal water nor police protection, if, in fact, he were isolated from society, abstractions of this kind might be true. But it is, of course, obvious that he is a citizen as well as a scientific worker, with a citizen's responsibilities; in Great Britain, indeed, a citizen of one of the world's oldest and greatest democracies. It is his duty, therefore, to make up his mind about the uses to which his work may be put, or the failure to utilize it, and to express his conclusions in no uncertain manner.

It seems, however, an excellent plan that the publications of the proposed organization should be quite objective, providing a forum where arguments on all sides can be clearly stated. On questions such as the 'frustration' of science, the suggested moratorium of discovery and technical application, the optimum conditions for organization of research, etc., there are various points of view. Differences between these may be major or minor. But at present there does seem to be a lack of the means of ventilating these discussions, nor is it beyond the bounds of possibility that should an overwhelming case be made out for a certain line of action by papers, for example, in the proposed journal, the organization itself might sponsor, or press for, such action.

In general, however, the awakening of scientific men and others to a sense of the social relevancy of their studies to the happiness and freedom of the people as a whole will be a great achievement.

Agriculture and Geology

Sir Daniel Hall, K.C.B., F.R.S.

The question at issue is whether it is worth while to promote the formation of a society to study the social relations of science. At the present time the man of science, perhaps more than anyone else, is conscious that the organization of society, national or international, is in need of guidance. He is also conscious that in such organization as exists, science is almost wholly ignored, though it is being used for ends which must eventually destroy science, on one hand for the intensification of the destructiveness of war, and on the other for the regimentation of public opinion and the suppression of free thought. Let us not mistake the omens—there exists in England to-day an intolerance of differing opinions and a desire to employ force against them, coupled with a contempt for science, except in its subordinate capacity to deliver 'goods', such as has never been known before in my lifetime. All the stupidities of the war-time are being revived in preparation of the war to come. What are the alternatives to the man of science? He can contrive his own personal escape, or he can join with others to promulgate his faith in the ultimate prevalence of reason and persuasion.

Can there be a society devoted to the scientific study of social relations? It may be asked, what else is a university? It should be such a society, but with all our gratitude for the free play of thought they contribute, universities actually take their colour from a relatively narrow range of society, and also in their faculties of law, literature, history and theology are trained the apologists for reaction and return to the past. In consequence, the men of science must constitute a university of their own, a research university which shall subject 'social relations' to scientific study. Such a university or society needs no buildings, but it does need money to pay its investigators. The men engaged in active scientific work can give guidance, stimulus and criticism in such a cause, but they cannot supply the time for the actual investigation.

The results may all seem futile enough—reports on subjects on which the political parties have already taken sides—but it will be proceeding by the only ultimate weapons science can use, by reason and persuasion.

Sir John Russell, O.B.E., F.R.S.

It is very important that the social relations of science should be more fully studied. During the past eighty years, both science and our social structure have developed enormously, and changed out of all recognition. How far the scientific developments have been responsible for the social changes it is impossible to say, but it is certain that they have had profound effects, both directly and indirectly.

These indirect effects of science are probably at a minimum in the totalitarian States, where the dictator plans the life of the nation, and allocates their respective roles to the different groups of the community. Social relations are thus reduced to their simplest form: the scientific worker has no occasion to concern himself with them, or indeed with anything more than the immediate results of his work, and the dictator can proceed at once to deal with any undesirable consequences.

In a democratic country like Great Britain, the problem is far more complex, and unless it is seriously studied it may yet prove the weakness that will bring democracy down with a crash, when confronted with the superior organization of a dictatorship. Science can give vast power to any small group of people who are in a position to use it, and they may use it either for good or for ill. Almost all scientific discovery can ultimately be put to evil use: even agricultural science, most blameless of all, has been perverted to the destruction of soils that had taken thousands of years to build up.

Some of the ultimate effects of scientific discoveries on human life have been very profound, though it would be unjust to attribute them wholly to science. Perhaps the most far reaching has been the moving away from religion as the basis of life and character that was so marked a feature of the older days. The firm belief in a just God who would redress in a future life the pains and sorrows suffered in this life undoubtedly gave our fathers a strong feeling of courage, hopefulness and optimism which many observers declare to be lacking to-day. This same belief also emphasized the responsibility of each individual for working out his own destiny, and so inspired a widespread spirit of self-reliance and sturdy individuality now much less common than it was.

Another important change has been the sweeping away of craftsmanship and the substitution of standardized machine products. It would be impossible now to build beautiful villages such as one can still find in the less known, and to use the house agents' word, 'unspoiled' parts of the countryside: and it is difficult to believe that the old craftsmen would have tolerated the blatant vulgarities proliferating in parts of Great Britain now being 'developed'.

A further consequence of the extension of the machine has been the segregation of a considerable class of people who are unsuited for industry, and who ask for nothing more than occasional unskilled work to eke out their doles, leaving them abundant leisure for the 'pictures' and football matches. They are found chiefly in the democratic countries, dictators having a short way of dealing with them, but they are a growing menace and likely to cause serious difficulties in the future.

It is safe to say that none of these developments was foreseen when science began its modern development, and certainly none was desired by the scientific workers. What further changes may be brought about and whether they are inevitable, could be discovered only by serious study, and it is eminently desirable that this should be undertaken.

Prof. P. G. H. Boswell, O.B.E., F.R.S.

Societies and committees seem to play such an active part in Western civilization that busy people may be expected to look askance at any proposal to re-orientate themselves in this respect. Yet, in the present state of human development, there can scarcely be any doubt as to the need for intensification and direction in the study of the social relations of science. Evidence of such need is seen, in fact, in the activities of the Engineers' Study Group, in the reactions of the sections of the British Association to the pressure of public opinion, and in the recent proposal of the Trades Union Congress to set up an advisory scientific committee. The question that at once presents itself is, can a new organization help forward the good work, or will progress be achieved better by the present haphazard method of disconnected discussion and dissemination by various publishing bodies?

If a Society for the Study of the Social Relations of Science could bring together results that would otherwise be scattered in sundry journals, one important plea for its establishment would be justified on the grounds of convenience. Then would arise the question of the scope of the society, a matter by no means easy to settle. Its scope, once agreed upon, would probably have to be circumscribed and quite likely in the direction of curbing the tendency to speculation which often plays a significant part in discussions of this sort. If, through the publication of papers concerned with the past, present, and possible future repercussions of science on social affairs, a balance could once be struck between unwise speculation and justifiable prevision, an important forward step would be taken. Foresight, as remarked by a well-known writer, is among the latest and most immature of mankind's attainments; certainly, from the moment early man turned from hunting to husbandry, the progress of human development (well expressed as "from the stone implement to the bank overdraft") has been characterized by increasing foresight and an urge to provide for the future. In the political sphere, the results likely to arise from individual or collective human action have necessarily long been the subject of careful thought, but this is not altogether true in regard to the results that may follow scientific discovery.

There seems, then, on the grounds of expediency alone, to be a definite case for the attempt to define the aims and activities of a proposed Society for the Study of the Social Relations of Science. The British Association is, of course, the singularly appropriate body at the present time to undertake this task, but various difficulties would require to be surmounted, including that of publication of original papers in full, if it took over the work of such a society itself.

Physics

Sir Henry Tizard, K.C.B., F.R.S.

There is nothing new in the fact that experiment and invention are transforming the habits of men and are adding to their problems. What is new is that we are all more aware of it, because the rate of change has been steadily increasing. Ease of communication, and the rapidity with which news can be conveyed throughout the world, emphasize the weak points in the social structure and tend to hide the good points. Bad news is, as a rule, better copy than good news. But can it seriously be argued that any section of society is worse off and living under worse conditions than a hundred years ago? Broadly speaking, the natural result of all scientific discovery has been greatly to improve the conditions of life and all our social relations, in spite of—or possibly even because of—the fact that scientific workers have been too busy doing their own jobs well to worry much about other people's.

Many men of science are, however, now taking a direct and vivid interest in the application of science to social problems. But it must be admitted that some of them go about the business in the wrong way. Many readers of Nature can think of scientific men who are most cautious in expressing opinions on scientific questions, who will always allow that there is a good deal to be said for the other man's point of view, who are content to settle the points of difference by careful experiment and study, but who appear, oddly enough, to have little hesitation in making loose and insufficiently considered statements on matters of great social and political importance. They are doing science a disservice, and they ought to be discouraged. A good way of discouraging them is to encourage the sane consideration of the big social problems of the future by scientific workers working in co-operation with other men.

For this reason I think it is well worth while to try the experiment of forming a society to advance knowledge by encouraging the discussion of social science, and by the publication of articles which have had the benefit of informed criticism before they are published. The forthcoming reports by the International Council of Scientific Unions will probably be of great interest, but of very little practical value. They will doubtless contain a mass of data which may eventually be used as a basis for a first-class work by a first-class historian, but they are most unlikely to form a trustworthy guide for national or international policy, or to help to an understanding of the future effects of science on society.

Prof. J. D. Bernal, F.R.S.

SCIENCE as a factor in modern society is uncontrolled; what it does and does not do is left largely to chance and to the operations of ill-understood factors. If we are to prevent it becoming uncontrollable and destructive of the very civilization it has built up, we must begin at least to understand how science and society interact. This is why I welcome the formation of the Society for the Study of the Social Relations of Science, and hope it may find a wide support among scientific workers.

The formation of such a society is a logical step. Science has grown so great that it must take cognizance of itself. We need to create a science of science. This means taking our own activity and the social environment with which it reacts as a new field of study. No existing scientific body could undertake such a task; their fields are already too well delimminated. The sociologists, economists and historians, on the other hand, although they see the wider aspects, cannot by themselves understand either the social implication of scientific or technical discovery or the social and economic conditions which are needed for their production. Only a broad body in which both sides could meet and pool their knowledge can lead to clarification and new understanding.

In the first place we want facts. We need to know the history of the relation of science to society, an aspect of history which has as yet scarcely been touched. Even more urgently do we need to know the present status of scientific research and teaching both in our own country and abroad. How many scientific workers are there? How are they financed? What do they do? How is their work co-ordinated and directed? How is it linked with the satisfaction of human needs and the removal of human evils? Until we have fairly adequate answers to these questions we have no basis for understanding the present or planning for the future. The answering of these questions, even setting them in an answerable form, is a task which should properly fall to the new society.

Research, discussion and publication would all have their place, and in that respect the S.R.S. would be fully analogous to any existing learned society. But the study of wholes is never such a simple and straightforward business as the study of parts, and it may well be that the exact modelling of the S.R.S. on existing learned societies may not be best adapted to the nature of the work it is to undertake. Only experience can decide, and it might perhaps be as well to defer the precise determination of its constitution until there has been the chance to consider the main outlines, and some of the preliminary work has been done.

Prof. P. M. S. Blackett, F.R.S.

THE suggestion that there should be formed a Society for the Study of the Social Relations of Science (S.R.S.) is greatly to be welcomed. One can see here the possibility of the growth of a society which may have a profound educative value. It is worth while, therefore, to consider at the outset some of the conditions that are likely to be necessary for this desirable end to be attained. Of course, these conditions themselves will probably be the subject of controversy. This emphasizes at once that the views expressed in communications to the society must essentially be controversial. If controversy be banned, sterility will certainly result. This raises difficulties in connexion with the proposed, and of course necessary, refereeing of papers. Though it is obviously essential to maintain a high standard in the presentation of the facts, it is equally essential to allow a wide freedom in the deductions from them. For the same social facts do not, in general, lead people of different political views to the same conclusions. If this is not admitted at the outset; if, on the contrary, following too closely the example of other learned societies dealing with more exact subjects, the S.R.S. strives after a pseudo-scientific unanimity of deduction from given social facts, then I fear little that is useful will be attained.

Closely related to this is the danger that the problem of the relationship of science and society will be too much simplified by over-emphasis on the brilliant achievements of scientific workers in their field, with the supposed incompetence of statesmen in theirs. This view is apt to lead to the naïve belief that it is only necessary to replace statesmen by men of science to put everything right—a fallacy which is quite often believed to-day, particularly by men of science.

On the positive side, it seems to me essential that the S.R.S. should have a strong historical bias, in the sense that the relationship between science and society should be considered historically in all its continually changing aspects. Special attention should be given to the reciprocal influence between social change and technical and scientific advance.

Consequently, the S.R.S. must be concerned as much with the impact of society on science, as of science on society: to separate the two is surely to miss an essential understanding of either. It is noticeable that the quotation from the resolution of the Council of the American Association for the Advancement of Science in the article on the suggested S.R.S. emphasizes only one side of this relationship.

If we are now to act usefully so as to remedy in the future our present discontents, we must not only know the facts of to-day, but we must also understand them; that is, we must know how the facts have come about. It is useful here to remember again the much quoted words of Descartes on the nature of things. "Leur nature est bien plus aisée à concevoir lorsqu'on les voit naître peu à peu en cette sorte lorsqu'on ne les considère que toutes faites."

Prof. F. A. Lindemann, F.R.S.

It is a commonplace to say that the whole circumstances of our civilization have been profoundly modified by invention based upon scientific progress. Everybody knows that greater changes were brought about during the reign of Queen Victoria than in the long interval between the coming of the Stuarts and the death of William IV. It is probably fair to say that the changes in the first twenty years of this century were as great as those which occurred in the last sixty years of the previous century; again, the last fifteen years have brought about changes greater even than those which marked the interval between the Boer War and the Treaty of Versailles.

When one observes the geometrical character of this progression and realizes the even more serious and, perhaps, sinister interventions which advances in the biological sciences almost certainly will render possible, one cannot but be anxious about the future. Our world picture has been fundamentally modified. Rightly or wrongly, the restraints of religion have been thereby to a great extent swept away. The facilities which science has provided have made it easy to substitute plausible, but superficial and often half-baked theories, and infect whole nations with beliefs and ideologies which in soberer times would have been scorned.

Whether a great deal can be done to prevent such abuses by the systematic study of the social relations of science it is not for me to say, but I am sure that all men of science will warmly welcome anything which could prevent the results of their researches being put to evil purposes, and will wish every success to any group or body of men working to that end.

Prof. H. Levy

A society for the study of the social relations of science is scientifically justifiable and socially urgent. Scientific workers, in the methods and criteria that they apply, in the range of their work, in the accumulating volume of discovery and invention that they bring forth, constitute a very distinctive section of social activity. They would be less than fully scientific if they were to remain ignorant of the social laws of change that they exemplify in their own group development. The proposal therefore implies a recognition of a shift in scientific interest from the physical and biological to the sociological. This shift has been stimulated by a sense of uneasiness prevalent to-day among scientific workers that all is not well with the way in which science is finding its application in social life. It has been argued that no scientific worker need concern himself with the social outcome of his work. Actually it is a fact that he does, and the proposal in question provides the evidence.

We are witnessing, therefore, a change in scientific focus, a change within science, the causes for which lie partly outside the narrow world of science itself. It raises again the important query, to what extent the trend of scientific development is or has always been conditioned by social forces. This constitutes one class of problem that falls within the scope of a society such as that proposed. The obverse of the picture presents the complementary problem in which science and technology as driving forces in social change have now become the causal agent, the effects of which are traceable in the social environment.

Both these studies argue the need for the exposure of social regularities of a qualitative and even of a quantitative nature, that are directly correlated with technological application. No scientific worker can deny that to clear up such issues is of first importance. No one of scientific temper can deny that many aspects of these problems form a fit and proper field for scientific study. The formation of a society charged with this specific task at a period of social uneasiness may well mark a significant departure in scientific work, as did the foundation of the Royal Society at the inception of the Industrial Revolution.

There are two difficulties that will have to be honestly faced from the beginning. First, it may be a very delicate matter on occasion to draw the line of demarcation between strictly scientific and strictly political issues in such a field. Those who turn their faces politically to the right or to the left have already formed convictions that they believe are scientifically well founded. It follows that the function of such a society must be like that of a sieve through which the scientific bases of such convictions must pass if they are to be other than mere prejudices. How, then, can this be achieved, if in fact many scientific workers, believing themselves unbiased politically, are perhaps unconscious of their own pre-judgments? In the face of this difficulty, I consider that the most suitable council for such a body would consist of a 'reasonable' group of scientifically minded people, along with 'right-' and 'left-wing' scientific men selected for their capacity to present a rational case, and for their power to subject papers presented to informed criticism. Acceptance or rejection of a paper would then depend on a capacity to convince the central section of the council of the validity of the contentions.

The second difficulty lies in the fact that the field of study would trench on those of sociologists and economists. The answer to this is that the task is a selective one, intimately bound up with the world of science, and that there is no evidence that economists or sociologists are particularly concerned with its specific problems. It may be that physicists, chemists, engineers, biologists, and mathematicians are better qualified for this special task, in the sense that they are more familiar with its technical details.

Finally, it is desirable, because of its nature, that the society should rest on as wide a membership as possible, while its influence should expand with the quality and authority of its publications.

Prof. A. Ferguson

ONE's first reaction to the proposal to add yet another to the set of letters that the unfortunate student of public affairs must memorize is one of automatic opposition; nor is that attitude modified after close consideration of the proposals put forward. That an urgent need exists for an organization which, without shirking controversial matters, shall examine and report on, in a purely objective and disinterested fashion, the social implications of advances in science, is to-day obvious to the point of being commonplace; and we can all join in wishing a fortunate outcome of the deliberations of the—what is the jargon ?—the C.S.S.R.

But is it necessary, or even advisable, to set up in Great Britain a new organization which shall be charged with the important and the urgent duties outlined ? What advantage is there, in these days when men's emotions continually run away with their reason, in founding an S.R.S. "with a large individual membership, which should not be confined to men of science, though they should play the principal part in it"? Youth has its generous enthusiasms—which are sometimes ill-regulated; and a young S.R.S., formed at a time when all sorts and conditions of rival propagandists are proclaiming, now and then with borborygmic rumblings, the virtues of their wares, might easily find itself taking a wrong turning. It is a difficult and nice business, in these excited days, to found a new society having such objects in view, and prepared to discuss them in an objective and judicial fashion.

There is at least one organization in existence which has the constitution adumbrated; which is alive to the consequences of the impact of science on a perplexed and unstable world; which is changing its alignment to meet the demands of the changing times; which has experience in the use of a mechanism capable of dealing with these problems more rapidly and more efficiently than that of a new and untried organization; which is not lacking in enthusiasm for the forwarding of world peace, and for an equitable social order; and at any rate is not likely to attempt to staunch a wound in the thigh by applying a tourniquet to the ankle.

The necessity for the existence of an organization which shall inquire, in an objective spirit, into the social relations of science is patent; it is obvious, too, that rapid, effective and well-informed action is called for; but it would be greatly to the advantage of all to consider the possibilities of the adaptations of mechanisms already in being, before adding yet another to the almost crushing burden of already existing societies.

Sir Richard Paget, Bt.

As Mr. Aldous Huxley has pointed out in "Ends and Means", the wise use of men's increased knowledge and power depends primarily on their ethical and philosophical outlook. From this point of view, the scientific problems for investigation are chiefly questions of psychology (especially of mass psychology) and education.

It is obvious that impartial investigation cannot be expected in the totalitarian States, and that there is therefore a great responsibility on Great Britain, the United States, and the other countries which still preserve a measure of intellectual freedom, to point the way to a better order.

Organized research in education is greatly needed. At present education depends mainly on books—that is, second-hand observation, inference, imagination, etc. There has been little, if any, scientific study as to the effects of such second-hand education as compared with first-hand contact with Nature, craftsmanship, and contact with the real problems of life.

As to the machinery of civilization, I venture to add the following, as subjects urgently needing scientific investigation in Great Britain—either by a new organization such as the suggested S.R.S., or by an extension of the British Association, or by the new Nuffield College at Oxford:

(1) *Imperfections of the monetary system.* This at present treats money primarily as a commodity rather than as a token for real wealth, that is, goods and services. It gives undue power to 'finance' as compared with that which is given to the producers of real wealth; it hampers the free production and consumption of wealth. It allows money to be bought and sold as a commodity, and thus causes instability in price-levels, and in the rates of exchange between the currencies of different nations. It also causes such gross anomalies as the destruction of real wealth—for example, wheat, cotton, coffee, fruit, fish, etc.—which cannot be utilized by those who would gladly consume them, because no additional 'tokens' (that is, money) are made available wherewith to purchase them.

The present economic system also forces each nation to strive for a favourable balance of trade as against other nations; this in itself is a perpetual stimulus towards national hostility.

(2) *Lack of statistics.* It has frequently been pointed out that efficient production and planning for future production are hampered by lack of statistics of production and consumption. It seems probable that adequate statistics, coupled with a rational monetary system—which equated the supply of money (and credits) to the production of real wealth—would greatly facilitate such production, and would obviate the present difficulties of selling the products of industry; this would incidentally save a large part of the great expense and labour incurred in advertising and salesmanship, and release a large personnel for further productive work. In the domain of public health also, much valuable information is probably lost by the lack of systematic medical statistics.

(3) *New Inventions.* At present there is no recognized system for investigating the merits of new inventions, and for supplying the capital wherewith to try them out. The consequent hardships—to which even the best inventors have been, and still are, subject—are notorious.

(4) *Changes of employment.* The rapid changes of technique and of demand for new industries appear to necessitate a corresponding system of training employees in new techniques, so that new industries can be developed without dislocation of present personnel. Experience during the Great War showed that such changes of employment can be effected much more easily than had been anticipated. The co-operation of the trades unions would, of course, need to be secured in the investigation of this problem —as also in that of the length of notice to be given to employees in industry in terminating their employment otherwise than for personal faults or inefficiency.

Chemistry

Prof. A. C. G. Egerton, F.R.S.

"Man learns from history that man never learns from history." Will the same be said, that man learns from science that science cannot help man ? Will a sociologist of the future find that the impact of science on the social organization had been a factor contributing to the better adaptation of those organizations against debilitating, disintegrating and disruptive influences, and that there was steady progress towards a higher state of being ? Or will it be said that the impact of science was to bring greater difficulties in its path than otherwise ?

On the material side, there is no doubt that the necessities of life can be obtained more easily as a result of the knowledge that man has gained through science. But is this facility gained at the expense of increased difficulties of a psychological and sociological character which are not so easily attacked by the scientific method ?

As a result of the application of science, the material conditions enabling a population to live within a given area can be assessed ; but we have only gone a little way towards carrying into effect the available material improvements. When we approach the complications confronting us in the application of the scientific method to biological and psychological problems and their influence on sociology, the way is not so clear. What would be the effect of the prolongation of the average length of life ? What would be the effect of increased leisure ? What are the psychological effects of the various habits of life of civilized man ? About such questions it is only possible at present to express an opinion, and no statement based on attack by the scientific method can yet be made.

Many matters in which human relationships come into play and about which action has to be taken are at present best dealt with by those responsible for government, who have the same experience towards such matters as the works technician has in applying his experience and rule of thumb methods to technical matters. Perhaps, as Ramsay MacDonald envisaged, the scientific method would eventually enter the realm of government and make the same advance as it has in the realm of technology. At present, however, the application of the scientific method to sociological problems has great difficulties.

A beginning can best be made, and has to some extent been made, by those responsible for government seeking the advice of men of science on all such matters in which their assistance can obviously be of advantage ; in connexion with nutrition, prevention of disease, agricultural policy, afforestation, denudation, pollution of air and water supplies, provision of power and of heat, conservation of resources, etc.

It is often said that the scientific worker should control the application of his discoveries so that they may be used for the general good, instead of allowing them to be employed haphazard or utilized by those tendencies which egg men on to ill. As matters stand at present, it is not possible for the scientific investigator or the technician to control in what direction his work will be utilized. The man of science has less power almost than anyone towards the direction of human affairs. He is not organized, he cannot strike or lock himself out without running counter to his ideals of an unbridled curiosity into the workings of Nature, and he is as a rule too liberal-minded and disinterested to wish to keep his knowledge secret after the manner of the ancient priesthoods. On the other hand, he cannot stand by and see his work desecrated by folly, and he should have more power to enable him to help prevent such desecration. How can this be achieved ?

Articles in Nature have suggested certain ways and means. By all means let questions of what help the man of science can give be discussed, studied and reported. But committees and reports are not enough. Responsible scientific men who have achieved respect in their own particular line of work must carry the responsibility of their position and should be ready to be the link between the specialist in their particular branch of science and those who are responsible for government.

Things happen in this way at present. The Royal Society has always provided such assistance as it has been asked to give. Unfortunately, what is done is not enough. In some countries responsible men of science are taken into greater confidence as advisers and leaders in the State. It is this that has to be encouraged, rather than the setting up of a number of committees the work of which it is no one's particular interest to further. It has been unfortunate that, at a time when the achievement through science has been so great, the advice of those who have brought it about has not been more sought in matters of policy. To this day even on the boards of companies which are directly exploiting the results of scientific developments, those who have been very largely responsible for those developments are not included. The technical man is still kept in his place. In fact it is only through their own force of character that men of science and technical men have shared in the control of affairs.

Perhaps the fundamental error of these days is that economic considerations are allowed to override all others, and at a time too when such values are not really essentially paramount, for through the command of natural resources the human requirements of life can nowadays be met (provided growth of population is to some extent controlled). Science, art and religion contain the basis of other values which must not be subservient to economic values. The pursuit of science has a value on its own account. The execution of a fine piece of experimental work or mathematical analysis has a beauty of its own, just as poetry and art have their particular appeal. It is this aspect of science which influenced such great men as Scheele and Faraday.

There must be men in each country to give effect to this sense of values. Those responsible for government should be able to consult with a permanent body, such as the Royal Society, which would be the focus of the various advisory councils needed, and the link with similar bodies in other countries. The British Association provides an adequate means for discussion of the various problems, but it is possible that executive action could best be taken through a smaller representative body such as the Royal Society, as close co-operation exists between the two organizations.

If an international council is appointed to work in collaboration with economists and politicians, I think that the appointments to such bodies should be made by collaboration between the Royal Society and the Government.

The substance of my remarks is that scientific men should be invited to take a closer and more responsible position in the affairs of State, and should be in closer touch with those responsible for government, as they were in the days of Charles II.

Prof. F. G. Donnan, C.B.E., F.R.S.

As a foreign member of the Amsterdam Academy of Sciences, I am very glad to have had the opportunity of associating myself with the action taken by that body, an action which led to the recent setting up by the International Council of Scientific Unions of a "Committee on Science and its Social Relations". There can be no doubt that this Committee is destined to carry out most valuable work, and its formation on such a secure international basis may well mark the beginning of a new era in the history of mankind.

The proposal to found in Great Britain a Society for the Study of the Social Relations of Science is one which I wish to support most strongly. The existence of such a society in this country—and of similar societies in other countries—would be the surest guarantee for the success of the great work initiated by the formation of the international committee.

The impact of science on society—to employ a now famous expression—is of two kinds. In its less obvious and yet perhaps finally most important form, it alters the general 'climate' of thought and opinion. In the nineteenth century, when steam-driven machinery in factories, steam-boats and railway trains, and the application of electrical science in the telegraph, telephone and electric light were changing the social and economic relations of people, the work of Wallace, Darwin and Huxley caused a fundamental change of general outlook. So also in the present century, with its vast organization of factory production and great power stations, its electric trams, motor-cars, aeroplanes, cinemas, radio, gramophones, etc., the great discoveries in physics, chemistry and astronomy have produced a profound effect on the general climate of opinion; whilst it is probable that the biological and psychological sciences are destined in no very distant future to effect another and perhaps still more drastic development.

It is with no intention of underrating the enormous effects of applied science on the social and economic conditions of humanity that I mention these matters. I want simply to suggest that we must pay equal attention to the influence exerted on the actions of men by the general outlook which they derive from the current scientific philosophy presented to them. It is of very great importance that this 'ideology' should be the best available.

In spite of everything that has been written on the subject, it is perhaps not yet sufficiently realized that the inhabitants of this planet are witnessing at the present time a very peculiar epoch in its history —the epoch of the enormously rapid advance of science and its applications. Although speculative prophecy is usually of small value, I am inclined to hold the opinion that this epoch will be a relatively brief one, confined (bar 'accidents' of a terrestrial or extra-terrestrial character) to the next ten thousand, or possibly the next two thousand, years. It is hard to say when the zenith of this peculiar period will be reached. Certainly nothing like it has ever been experienced before by the inhabitants of this earth. Will its effects be beneficial or catastrophic? That is the serious question to which civilized humanity is now slowly awakening. Modern science is the revelation to mankind of possibilities and potentialities undreamed of even by such giants as Galileo, Newton and Harvey—undreamed of, therefore, only a few hundred years ago. What will a Wellsian historian, writing, say, in the year 20,000, have to say of this epoch?

In the somewhat complacent mixture of romanticism and utilitarianism which characterized the nineteenth century, many men, intoxicated by the advances of that age, dreamed of a continuous upward progress of humanity. Wiser, or perhaps more disillusioned, than they, we of this century are by no means sure of such a continuous progress. Many see a possible, or even probable, danger of collapse. Such a crash of civilization could never be due to the true advance of scientific knowledge, though it might be accelerated by the inhuman and anti-social use of this knowledge, and by a false ideology based on a perverted interpretation.

I think that one of the main objects of the new society will be the careful study of the reversible social-scientific reaction, science $\rightleftarrows$ human welfare; how by the advance of science to increase human welfare, and how by the advance of human welfare to increase science. This is one of the great dynamic equilibria of a beneficent and benevolent civilization.

At the same time we must avoid the errors of an easy sentimentalism founded on august abstract nouns and grandiloquent phrases. Human society and its welfare are extremely difficult and complicated matters, the hard, concrete realities of which demand detailed and highly critical study. Although we may reject the application to human society of the holistic conceptions of the beehive and the termitory, or the idea of the flowering of a great aristocracy based on a partial de-humanization of the rest, it will be for the biological and psychological science of the future to say what are the possibilities and what may be the best available solution. Unlike traditional philosophy and traditional theology, science does not attempt to storm the citadel of truth ; it rests on patient experimental research, and offers no simple panacea and no facile Utopia. Great and immense, therefore, are the prospects and potentialities of the new society, for they will be based on the essential fluidity and adaptability of scientific thought, the steady progress of discovery, and the slow building of whatever conception of the *summum bonum* mankind is capable of attaining. There may be room here for personal optimism or pessimism, but none for tears or an inaction born of despair.

Prof. John Read, F.R.S.

The furtherance of the ideal under discussion will depend largely upon the character of science teaching in the future. Such teaching in the past has consisted too often of a systematized inculcation of facts and theories, unillumined by any adequate reference to the bearing of these facts and theories upon everyday life, or to their influence upon the development of modern civilization. A neglect of the historical and humanistic aspect of science has been equally pronounced : incidentally, the scientific worker's neglect of history has found a counterpart in the historian's neglect of science.

A frequent consequence of what may be called the teaching of science in blinkers has been a soulless and uninspiring presentation of a vast field of human thought and endeavour which is fraught with possibilities as an instrument of education, as distinct from instruction. Dr. George Sarton has well said that "the more science enters into our lives, the more it must be 'humanised', and there is no better way to humanise it than to study its history. Such studies, reconciling the purely scientific, the historic, and the philosophic points of view, would be the source of the soundest and highest idealism." The man of science is a pioneer and an architect of human progress, and as such he should cultivate a wide vision. Only by so doing will he be able to help efficiently in building up a human society capable of appreciating the spirit and method of science, and of putting the discoveries of science to sane and effective uses.

Prof. J. C. Philip, O.B.E., F.R.S.

The significance of scientific method and scientific discovery for social and economic conditions, national and international, is increasingly recognized, and the proposal to provide a specific forum for the exposition and discussion of the relevant problems merits cordial support. In the columns of Nature, from time to time during recent years, the importance of these problems has been stressed, and it is entirely appropriate that the Editor should initiate suggestions for a further definite step in this matter.

Scientific men are often regarded as standing aloof from common human interests, and indeed their own attitude has frequently given support to this view. Some have been inclined to rate the value of science as inversely proportional to its utility and to the extent of its contact with the practical affairs of life. In the world situation of to-day, however, when the frequently serious economic consequences of technical development and the extensive application of scientific knowledge to destructive ends are only too evident, such a detached attitude becomes impossible for a reflecting man.

Advancing knowledge has outstripped the development of social ethics, and one feels that, however marvellous the discoveries of the last fifty years may be, their applications have in many cases provided only "improved means to unimproved ends", as Mr. Aldous Huxley has put it recently. It is time that vision and brains were devoted, not so much to the extension of the boundaries of knowledge, as to a serious and systematic examination of the problems which the discoveries of science have created.

A society for the study of the social relations of science, such as is now proposed, would provide opportunity for the dispassionate investigation of these pressing questions. Operating in conditions of objectivity and free discussion, the society should attract the sympathy and support not only of scientists but also of others to whom the welfare of the community is a major concern.

Dr. C. H. Desch, F.R.S.

The effects produced on society by the growth of science fall into three main categories : the changes in material conditions caused by inventions ; the influence of scientific thought on the intellectual outlook ; and the increased appreciation of the mutual dependence of peoples. It is the first of these which attracts most attention, and seems to offer the most fruitful field for such an organization as is suggested, but the other two are no less important. Although the present is called the Scientific Age, mainly on account of its material achievements, it is doubtful whether current views on social questions are appreciably affected by scientific ideas. The history of scientific discovery and thought, the scientific interpretation of historical events, and the study of such concrete problems as the conservation of natural resources and their relation to international trade, fall into the third category.

In discussions on this subject, 'science' has too often meant only the physical sciences. No doubt public interest in nutrition and in eugenics has done much to bring biology into the field, whilst popular interest in psychology even proves embarrassing from its failure to distinguish science from charlatanism, but science remains incomplete unless it includes sociology, in the Comtean sense of a synthesis of the social sciences. In the public view, its place has usually been taken by economics, which deals only with a single aspect of social life. Unless science be understood to embrace social as well as physical and biological phenomena, it would seem impossible to bring it to bear effectively on social conduct.

As science becomes more specialized, so that workers in different branches find it increasingly difficult to understand one another's language, the need for a synthetic outlook becomes more urgent. This view has been frequently expressed in NATURE.

It is regrettable that so few workers in experimental science have taken a keen interest in social science, if we except the recent enthusiasm in some quarters for the Marxian system, which exalts the economic above all other social factors. The Sociological Society (founded 1904, since 1930 the Institute of Sociology) has attracted few scientific workers, in spite of the early efforts of Francis Galton and Patrick Geddes, but it would seem an appropriate centre for discussions of the social relations of science, whilst the annual gatherings of the British Association afford an excellent opportunity for bringing results before the public. It needs to be shown that a new society, unless its programme be very carefully thought out and some guiding principle of synthesis adopted, would do the work better than existing organizations. There will be general agreement as to the need for such action as that suggested, but it is not clear that the solution proposed is the best.

Summary

THE comments in the foregoing letters may be conveniently summarized in three groups: *why* is it necessary to go deeper into the social relations of science, *what* are the activities envisaged, and *how* can they best be brought about.

The rapid and persistent growth of natural knowledge leads to effects which have to be correlated (Bragg, Fleure). There is a need for intensification and direction in the study of the social relations of science (Boswell) and guidance in the organization of society (Hall). All is not well in the way science is applied to social life (Levy). The liberty of science is threatened (Hopkins). Social developments are ill-balanced (Bartlett, Philip) and may destroy civilization (Bernal, Donnan, Kerr, Lindemann).

The social problems created by science can be solved by scientific method (Flugel) but educative action is needed both for scientific workers (Blackett) and for other citizens (Kerr). As the sciences become more specialized, the need for their synthesis increases (Desch, Salisbury, Spearman) and also that for a closer relationship between scientific and social workers (Laski, Marquand, C. S. Myers). It is the duty of scientific workers, as citizens, to study the social implications of science (Needham, Stopford) and to see that Government and legislature receive the best advice from those scientifically qualified (Egerton, Ryle).

The proposed organization would provide a meeting place between men of science and others interested in statescraft (Crew) and would prevent them from going about the business in the wrong way (Tizard). It should study the social background of science (Le Gros Clark), the historical relations between science and society (Blackett) and, in general, the reversible reaction science ⇄ society (Donnan). In particular, it would investigate the repercussions of science on social affairs and also likely future developments (Boswell, Russell).

As specific problems, it might find out the number of scientific workers, how they are financed and how their work is co-ordinated (Bernal, Huxley, Needham) and might draw up a code of ethics for them (Hill). The mechanism of production, the unsatisfactory method of dealing with new inventions, the imperfections of the financial system, the lack of statistics, problems of employment and ecological studies also deserve attention (Sargant Florence, Paget, Salisbury).

The organization envisaged should eventually humanize scientific teaching (Read), bring together results scattered in many journals (Boswell), act as co-ordinating body to other societies (C. S. Myers) and encourage them to study specific problems—for example, the anthropological and folklore societies might inquire into the springs of human action (Fleure). It should obtain and distribute funds for research (Huxley, Hall, Wells) and might eventually act as information bureau and consultative body for administration and industry (Flugel, Huxley).

The need for preventing unnecessary duplication is stressed, particularly with reference to the activities of the British Association, the Royal Society and the Institute of Sociology (Ferguson, Egerton, Desch). Sociologists would welcome co-operation (Farquharson) and the proposed organization might grow into a section of the B.A. (Crew).

Other than scientific workers should be welcomed as members (Hopkins, Levy, Philip, Stopford). Sociology should be well represented (Ginsberg). Representatives of the chief societies interested in social questions should be included (C. S. Myers) but membership should be individual (Haldane). Manual workers should be allowed to join (Haldane) but economic quacks should be excluded (Marquand).

Apart from one correspondent (J. L. Myres) the comments and criticisms are mostly constructive. The chief difficulties foreseen are in connexion with retaining a cool, scientific attitude towards emotional and political subjects (Ferguson, Chalmers Mitchell, Stopford) and of obtaining a fair, unbiased board of referees for the publications (Blackett, Haldane, Levy). Here, perhaps, the First Interim Report on Schemes and Proposals for Economic and Social Reforms, published by the British Science Guild and the Engineers' Study Group (see NATURE, May 25, 1935) shows that at least one group of investigators found that the problem was not insoluble.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST. ALBANS

tions of this, his favourite, field of research, and did his best to build up really adequate series upon which future systematists could work. It will require the labour of two or three generations of systematists to exhaust the possibilities of the material now available. It is to be hoped that the Tring Museum will be carried on as a living institution and that enough neighbouring land can be acquired to admit of future extension.

Protection of Aborigines

Recent correspondence in the Press has shown that there is a considerable body of public opinion which is still far from satisfied with the treatment accorded the races of backward civilization under British jurisdiction, notwithstanding the undoubted improvement in conditions and a more sympathetic attitude towards them to be observed in recent years. With a view to the possibility of further improvement, it has been decided by persons and organizations interested in the problem to hold a public meeting for the discussion of the question of their preservation. The meeting will be held by permission of the Council of the Royal Empire Society in the Assembly Hall of that body on April 28 at 3.45 p.m. The chair will be taken by Lord Moyne, who will speak on "Natives in the Solomon Islands". Other speakers will be Dr. W. van Waterschoot van der Gracht, president of the Pygmy Sub-Committee of the Nederlandsche Commissie voor Internationaale Natuurbescherming, on "The Preservation of Backward Primitive Races"; Dr. John R. Baker on "The Natives of the New Hebrides"; and Dr. Julian Huxley, who will deal generally with the preservation of primitive cultures. Tickets of admission, which is free, may be obtained from the Secretary, Aborigines Protection Society, Denison House, 296 Vauxhall Road, S.W.1.

Indian Cultural Studies

Notwithstanding the assurance that the Indian collections of the Victoria and Albert Museum, South Kensington, were not to be dispersed and that space would continue to be provided for them in the galleries of that Museum, which followed Mr. de la Valette's lecture before the Indian Section of the Royal Society of Arts (see Nature, December 25, p. 1108, and January 29, p. 177), the critics of the methods of the ethnographical sections of our national collections are still of the opinion that less than justice is done to requirements for the study of the cultural history of India, compared with what might be attempted with the resources at command. A joint committee accordingly has been formed, consisting of representatives of the five bodies more intimately concerned in the study of India and her peoples. These are the Royal Society of Arts (Indian Section), the India Society, the Royal Asiatic Society, the East India Association and the School of Oriental Studies. Although the joint committee has as yet, it is understood, arrived at no decision as to its precise aims and methods of procedure, in principle the general purpose is to secure provision which in scope and display, dignity and standing, will be worthy of so great a dependency as India, with its tradition of advanced civilization stretching back thousands of years, and as the place of origin of at least one of the religious systems of the world's history. The traditions of the Victoria and Albert Museum, though it included 'industry' in its original purview, are not such as to foster a treatment of Indian culture in which technology and the humbler arts of life have no less claim, if not indeed a stronger claim, to treatment than fine art. But while the Indian collections continue to be merely a department of a larger unit, they must be subordinated to the purpose of the whole. The joint committee has been criticized, notably by the writer of a letter in *The Times* of March 23, as academic; but surely if its purpose is rightly understood, it is precisely the academic spirit which it aims to avoid. What could be more closely in touch with modern India than a comprehensive museum of Indian culture, which should cover both past and present ?

University of Birmingham

At the last meeting of the Council of the University of Birmingham, the following resolution was passed: "The Council has considered the recommendation of the Finance and General Purposes Committee with regard to the pressing needs of the Department of Physics, involving a capital outlay of about £60,000. It unanimously recognizes the urgency of the requirements, but, owing to the present state of University finance, regrets that it is not possible at present to put this work in hand. It is, however, most desirable in the interests both of teaching and research that there should be no delay, and the Council would be most grateful for any financial help from outside to enable the University to meet these requirements." This is a sequel to a report on the needs of the Physics Department made to the Council by Prof. M. L. Oliphant, who points out that the equipment and general facilities of the Department are totally inadequate for present needs. The time has come to review the temporary expedient adopted twenty years ago of having a considerable portion of the Department in old army huts.

The scheme for extension of the Physics Department proposed by Prof. Oliphant includes an additional block which would consist of a large central research hall suitable for high-voltage work, flanked by a number of research rooms, a machine room, workshop, dark rooms and a basement room for high-energy X-ray work. The general idea is that the buildings themselves should be simple and less costly than those of the remainder of the University, and the design should be elastic to be capable of readjustment with the changing needs of physical research. The present building could then be used entirely for teaching work and accommodation of staff. Unfortunately, it appears that architectural considerations require that the frontage to the great court should be of the massive and costly type exhibited in the rest of the University building as a whole, though the rear part radiating out behind the curved frontage might be of the relatively cheap design favoured by Prof. Oliphant. The financial stringency indicated in the resolution of the Council is due to the heavy expenditure required for the completion and equipment of the new Medical School. The needs of the University of Birmingham, particularly in such a subject as physics, should have a first call on the generosity of Midland industrialists.

Protection of Wild Fowl

THE Wild Fowl Enquiry Sub-committee of the British Section of the International Committee for Bird Protection was received on April 6 by Sir Samuel Hoare, the Home Secretary, to discuss the question of the further protection of wild fowl. The deputation, which was introduced by Mr. Perch R. Lowe, chairman of the sub-committee, included its secretary, Miss P. Barclay-Smith, and representatives of bodies interested in the preservation of wild life and of museums. The immediate object which this sub-committee has in view is to promote legislation aimed at the prevention of the importation of wild duck and wild geese into Great Britain during the close season. There is also the further question of preventing the exposure for sale of wild duck during the same period and also of extending the close season to such limits as would be in the interests of the wild duck, sportsmen, and everyone concerned. At the present moment, large consignments of wild duck are shipped from Holland to British markets during our close time, having been caught in the many decoys which that country possesses. In view of the threatened diminution of the status of wild duck brought about by the many adverse factors affecting their welfare at the present time, the commercialization in Europe of any bird habitually shot for either sport or food, or both, cannot rationally be allowed to continue during both the open and close season. It will be remembered that the present sub-committee was successful last year in getting legislation set up to prevent the importation of quail into Great Britain during the close time.

Royal Botanic Garden, Calcutta

A NUMBER of men of science from Great Britain and elsewhere who were attending the jubilee meeting of the Indian Science Congress in January last were able to be present at the celebrations of the hundred and fiftieth anniversary of the Royal Botanic Garden, Sibpur, Calcutta, a note on the history of which appeared in NATURE of January 1. Sir James Jeans, president of the Congress, congratulated the Garden on its anniversary. Sir Arthur Hill, director of the Royal Botanic Gardens, Kew, in his address, stated that it was the first time a director of the Royal Botanic Gardens, Kew, had been to India in his official capacity. Sir Arthur pointed out the similarity in position, scientific interest and æsthetic beauty between the two Gardens. He emphasized the importance of the Sibpur Garden, and expressed the hope that the Government of Bengal will recognize its importance and that the necessary funds will be forthcoming both for the maintenance of the scientific staff and for the upkeep of the living collections. Sir Arthur suggested that Sibpur should, like Kew, serve as a training ground for student gardeners, in order that the many good gardens and parks in India may be maintained at a high standard of excellence. To this end, he suggested that the practice of sending men from Kew to Sibpur as instructors or curators should be continued.

DR. K. BISWAS, the present superintendent of the Royal Botanic Garden, Sibpur, referred to the keen interest taken in its welfare by the late Sir Jagadis Chandra Bose, and also by the late Prof. Hans Molisch, both of whom frequently visited the Garden. Dr. Biswas briefly reviewed the history of the Garden, most of the superintendents of which have been botanists of eminence. Economic botany naturally takes first place in the activities of its scientific staff, and Dr. Biswas gave examples of what has been and is being done in this direction, for example, cultivation and utilization of teak, jute, cotton, flax, tobacco, rubber, coffee, cocoa, etc. The Garden also offers good scope for the study of the tropical flora; 1,500 species are under cultivation. In fact, Indian botany is offered excellent opportunity for advancement with the help of the Royal Botanic Garden, its excellent Herbarium and its Library at Sibpur, Calcutta.

British Empire Cancer Campaign

AT the recent quarterly meeting of the Grand Council of the British Empire Cancer Campaign, a further grant of £1,000 for one year was placed at the disposal of the North of England Council of the Campaign to enable the short wave investigations to be continued under the direction of Dr. F. Dickens and Dr. S. F. Evans. This work, which is a continuation of that which appeared in the last Annual Report of the Campaign and in a recent issue of the *American Journal of Cancer*, concerns the investigations of the effect of varying forms of heat upon malignant tissues. It was also decided to allot a further sum of £1,338 for one year for the extension of the national propaganda work being carried out by the Central Propaganda Committee. Sir Charles Gordon-Watson, vice-chairman of the Clinical Cancer Research Committee, reported that the organization for the statistical cancer inquiries in the teaching and special hospitals of London and the hospitals of the London County Council and the Middlesex County Council has now been completed. He stated that all these Institutions have appointed registrars to take charge of the records at their respective hospitals and that the headquarters' arrangements are being perfected to deal with the data concerning more than 17,000 new cases of cancer yearly in the metropolitan area of London. The Grand Council confirmed the recommendation for the appointment in the near future of a full-time medical secretary and registrar at headquarters for this purpose.

Civil List Pensions

THE following pensions, among others, were granted during the year ended March 31, 1938, and are payable under the provisions of the Civil List Act, 1937, whereby the total amount has been increased from £1,200 to £2,500: Miss Alice Mary Buckton, in recognition of her services to literature and of the services rendered by her father, the late Mr. George B. Buckton, F.R.S., to entomology (£50 additional to the previous pension of £60); Mrs. Agnes Maud Carey, in recognition of the inventions of her husband, the late Mr. Robert Falkland Carey, in connexion with the discharge of aeroplanes from ships (£25 additional to the previous pension of £75); Miss Evelyn Marie Jeanette Dupré, in recognition of the public and scientific services rendered by her father, the late Dr. A. Dupré, F.R.S. (£75); Dr. Frank Elgee, in recognition of his services to archæology and geology (£130); Miss Alice Everett, in recognition of her own and her father's services to physics and other branches of science (£100); Miss Rachel Mary Fleming, in recognition of her services to anthropology and geography (£20 additional to the previous pension of £80); Prof. James John Guest, in recognition of his services to science (£100); Sir James Marchant, in recognition of his public and social services (£30 additional to the previous pension of £75); Mr. James Reid Moir, in recognition of his services to prehistoric archæology (£110); John A. J. Starkey, Marjorie M. J. Starkey, Jane R. Starkey (during the minority of any one of them), in recognition of the services rendered by their father, the late Mr. James Leslie Starkey, to archæology (£210 in trust).

Announcements

THE Linnean Gold Medal for 1938 of the Linnean Society of London has been awarded to Sir D'Arcy Thompson, professor of natural history in the University of St. Andrews.

SIR DAVID PRAIN has been appointed president for life of the Imperial College of Tropical Agriculture. Sir David, who celebrated his eightieth birthday on July 11 last (see NATURE, July 17, 1937, p. 98), was director of the Royal Botanic Gardens, Kew, from 1905 until 1922. He was a member of the Tropical Agricultural College Committee appointed by Lord Milner in 1919 and had been vice-chairman of the Imperial College of Tropical Agriculture from its foundation in 1921 until last year, when he retired. His appointment as life-president of the College is a particularly fitting honour which, it will be the general wish of all scientific workers, he may enjoy for some years.

SIR MERRIK BURRELL has been awarded the Gold Medal of the Royal Agricultural Society for distinguished services to agriculture. Sir Merrik was president of the Royal Agricultural Society and chairman of the Council of Agriculture for England in 1936, and for many years was chairman of the Society's committee which founded and administered the London Quarantine Station before it passed into the control of the Ministry of Agriculture.

WE regret to announce the death of Mr. J. E Marsh, F.R.S., demonstrator in the University Museum, Oxford, from 1886 until 1930, on April 13, aged seventy-seven years.

ON April 17, a new British record for gliding was made by Mr. C. Nicholson, who flew in his Rhonsperber sailplane from Huish (Wilts) to East Bigbury, near Plymouth, a distance of 122 miles. The previous record was held by Mr. P. A. Wills, who flew 104 miles from Dunstable to Pakefield on July 5, 1936 (see p. 714). On April 18, Mr. J. S. Fox broke Mr. Nicholson's record by flying in his Rhonadler sailplane from Huish to Fowey, Cornwall—a distance of 144 miles.

THE British Association announces that Charles Darwin's home, Down House, Downe, Kent, and the gardens and grounds, are open from 10 a.m. until 6 p.m. daily until September 30, including Sundays. Admission is free.

THE annual Congress of the Ophthalmological Society of the United Kingdom will be held at the Royal Society of Medicine, 1 Wimpole Street, W.1, on April 28–30, under the presidency of Dr. Gordon Holmes. Further information can be obtained from the Secretary, 7 Queen Street, W.1.

THE sixteenth International Congress of Physiology will be held at Zurich on August 14–18 under the presidency of Prof. W. R. Hess and will consist of six sections devoted respectively to general and comparative physiology; biophysics; biochemistry; applied physiology (sport, aviation); psychophysiology; pharmacology. Further information can be obtained from Prof. Rottler, Sonnenweg 6, Basle, Switzerland.

AN earthquake of moderate intensity was recorded at Kew Observatory on April 13. The first movement reached Kew at 2 hr. 49 min. 23 sec. G.M.T. and the records indicated that the epicentre was 1080 miles away, probably in southern Italy.

A UNIT for clinical research in surgery has been established at Edinburgh by the Medical Research Council, acting jointly with the Royal Infirmary, the University, and the Royal Hospital for Sick Children. The unit will be located in the Infirmary, with facilities also in the University Department of Surgery and at the Hospital. The director is Mr. W. C. Wilson, who has for this purpose been appointed to the whole-time staff of the Council. The arrangement has at present been made for a period of five years, as from April 1, 1938. The establishment of 'units' or departments of this kind in selected hospitals forms part of a policy adopted by the Medical Research Council for the promotion of research work in clinical science, as opposed to the laboratory branches of medicine.

ERRATUM. In the letter entitled "Occurrence of the Freshwater Medusa, *Craspedacusta sowerbii*, in Eastern Canada" by the late Prof. H. B. Fantham and Dr. Annie Porter in NATURE of March 19, on p. 515, col. 2, line 26, for 1938 read 1937, and on p. 516, line 37, for 32·03 read 32·30.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 753.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Recent Solar Eruptions, Auroras, and Magnetic Storms

IN connexion with the aurora of January 25–26, 1938, discussed in detail in NATURE of February 5, p. 232, it may be of interest to report that a brilliant and prolonged solar eruption and an unusually severe radio fade-out were observed at the Commonwealth Solar Observatory, Canberra, on January 24.

Owing to cloudy weather, the first spectrohelioscope observation of the day was not made until 1512 Eastern Australian Standard Time (0512 G.M.T.; all times which follow are G.M.T.). An exceptionally large eruption was then seen to be in progress around the large spot group at 22° N., 80° W.; from then until 0700, when the intensities were still high, observations were made through breaks in the clouds. No abrupt changes in intensity corresponding to the maxima observed in the aurora were noted, although curved prominences, similar to Pettit's Sunspot Type[1] (Class 3*b*), developed between 0519 and 0540.

One of the severest short-wave radio fade-outs ever recorded with the Observatory automatic $P'f$ equipment began at 0250. The ionospheric echoes during the morning were fairly normal, but disappeared suddenly at 0250, and no further echoes were recorded until 0645 when weak reflections from the F_2 region were observed. A further fade-out of signals occurred at 0700, followed by a rapid increase to normality by 0745. From previous experience of the correspondence between bright hydrogen eruptions and radio fade-outs it appears almost certain that the large eruption first seen with the spectrohelioscope at 0512 actually began a few minutes before 0250 G.M.T.

During a period of more than eighteen months of observations with the spectrohelioscope, we have found that, whereas a severe eruption is frequently followed by a number of small eruptions around the same spot group, on no occasion has it been followed within a few hours by another large eruption. Hence it appears likely that the remarkable aurora of January 25 was connected with the unusually prolonged period of intense solar activity commencing about 0250 described above, rather than with a later eruption occurring after sunset here.

The interval between the beginning of the earlier eruption and the reported time of commencement of the auroral display was 39 hours (or 35 hours if the very much smaller and later eruption at 0700, indicated by the radio observations, be taken as the time of the eruption responsible). The magnetic storm which accompanied the auroral display was reported[2] as commencing at 1151 G.M.T. on January 25. The interval between the beginning of the eruption and the outbreak of the magnetic storm was thus 33 hours, although the storm did not become intense until 1730, corresponding to an interval of 38½ hours. These times are considerably greater than the average (about 26 hours) given by Hale[3] for the interval between solar eruptions and corresponding magnetic storms and auroras. It would thus appear that the velocity of projection of particles at small angles to the sun's surface is considerably less than that along the normal.

The magnetic storm recorded at Abinger[4] at 22½ hr. on January 16 can be satisfactorily related to solar activity occurring earlier on that date. No spectrohelioscope observations were possible at Canberra on that day; but a severe fade-out, commencing at 0040 G.M.T. and lasting several hours, indicated without doubt the occurrence of a major eruption, probably connected with the same spot group then 30° E. of the central meridian, commencing at that time. The time interval in this case is 22 hours. This group, then 34° W. of the central meridian, was also very active on January 20–21. From the first spectrohelioscope observation at 2314 on January 20, until 0125 on January 21 there was considerable activity. At 0202 an eruption of importance 2 on the I.A.U. scale was in progress, the intensity gradually decreasing until conditions approached the normal at 0240 G.M.T.

The radio observations showed abnormally poor reflection conditions from 1950 January 20, culminating in a fade-out at 0150 January 21. A further fade-out of short duration occurred at about 0715 G.M.T.

An aurora was observed just after dusk at Canberra, at 1030 on January 22, although it probably began some considerable time before it was first noticed. An intense magnetic storm began at approximately 0500[4] on the same day. Although the connexion here is not quite so definite, it seems probable that the corresponding time lags, taking the radio fade-out times as indicating the commencement of the eruptive activity, were either 32½ or 27 hours for the aurora (though this time may be too great by a few hours) and 27 or 21½ hours for the magnetic storm.

Eddington's Fundamental Equation

IT is well-known that Eddington has obtained the equation[1]

$$10\,m^2 - 136\,m.m' + m'^2 = 0 \quad . \quad . \quad . \qquad (1)$$

where m' is the mass of a 'scalar particle', that is, a particle the expectation values of the spin and charge of which are zero, and m the mass of a charged particle with spin ℏ/2. The two values of m are shown to be associated respectively with the two signs of the charge, and writing them as m_p and m_e, we have

$$m_p : m' : m_e : : 1847{\cdot}6 : 135{\cdot}9 : 1.$$

Now the only property of the scalar particle that Eddington has used is that it may be described by a scalar strain vector, for which all the coefficients except s_{16} (the probability density) are zero. He saw that such a strain vector could be used to describe our knowledge of a particle when no observation of its charge or spin had been made, and so wrote that the scalar particle is "a particle which (so far as our information goes) has equal probability of being a proton or electron and equal probability of either direction of spin . . . a mathematical fiction, having no counterpart in experimental physics"[2]. However, it is not necessary to regard the scalar particle in this way, for it may be treated as a particle with as much independent existence as is usually ascribed to the neutrino. Then, according to Eddington's theory, it must have zero charge and zero spin (so that it may be represented by a scalar strain vector) and a mass $m' = 135{\cdot}9\ m_e$ in order to satisfy (1). If this particle were to combine with an electron or positron with the emission of a neutrino, it would yield a heavy negative or positive electron obeying Bose statistics and with mass between 136 and 137 times that of an ordinary electron.

This result is so closely in agreement with the U-particle theory of Yukawa[3], Bhabha[4], and others, which is in turn supported by facts, so far as present experimental accuracy goes, that it seems very unlikely that equation (1) can be fundamentally wrong, even although the way in which it is obtained is difficult to understand. That the equation should give, in addition to the mass ratio of the proton and electron, the right order for the mass ratio of the electron and a neutral spinless particle (and this before the heavy electron theory was put forward) suggests that Eddington's theory merits more attention than is usually given to it.

X-Ray Study of Thymonucleic Acid

A FEW years ago an occasion presented itself of examining by X-rays a small specimen of sodium thymonucleate kindly provided by Prof. W. J. Schmidt[1] of Giessen, and an imperfect fibre photograph was obtained with a strong period along the fibre axis of about 3½ A.; but the observation was not followed up at the time. We have now continued the investigation with material prepared in the Department of Chemistry of the Caroline Institute, Stockholm, by the method of Hammarsten and Bang[2]. The viscosity and double refraction of flow of this material in aqueous solution were the subject of a recent communication in NATURE by Signer, Caspersson and Hammarsten[3].

Films of sodium thymonucleate stretched some 250 per cent have been found to give a striking, though still rather obscure, X-ray fibre photograph in which by far the most prominent reflection corresponds to a spacing along the fibre axis of 3·3$_4$ A., *which is almost identical with that of a fully extended polypeptide chain system,* such as β-keratin[4] or β-myosin. The true period along the fibre axis is much greater than this—perhaps seventeen times as great, to judge by the present photographs—and there are also side spacings up to about 26 A., the best defined being one of approximately 16·2 A.

In view of the hydrodynamic and optical properties of the solutions[3] and of the optical properties of the solid fibres[1], the natural conclusion from the X-ray data is that the spacing of 3·3$_4$ A. along the fibre axis corresponds to that of a close succession of flat or flattish nucleotides standing out perpendicularly to the long axis of the molecule to form a relatively rigid structure, strongly optically negative, and showing double refraction of flow. At first sight the distance 3·3$_4$ A. between successive nucleotides might seem improbably small, but it is confirmed by the high density, which is 1·62–1·63 gm./c.c. for the dry substance. (Compare the density of ascorbic acid, 1·74, the flat molecules of which are piled together at an even smaller distance (3·16 A.)[5]). The average weight of a sodium nucleotide is roughly 330, whence if A be the average area :

$$3{\cdot}34 \times A \times 1{\cdot}62 = 1{\cdot}65 \times 330 \text{ (approx.)};$$

which means that the average area per nucleotide should be about 100 A.^{2}, as it clearly must be from known interatomic and intermolecular distances (a plausible estimate for the purine nucleotides gives something like 15 × 7½ A.^{2}). Again, the X-ray data lead to an estimate of the molecular weight (between 500,000 and 1,000,000) similar to that already arrived at by other methods[3]; for we may assume an effective average width of the molecule in solution of about 20 A., and therefore from the hydrodynamic data, which indicate a length to width ratio of roughly 300 : 1, infer a length of the order of 6,000 A. Such a length would contain some 2,000 nucleotides of thickness 3·3$_4$ A., and so would agree well with the weight just quoted.

The significance of these findings for chromosome structure and behaviour will be obvious. It seems difficult to believe that it is no more than a coincidence that thymonucleic acid consists of a long succession of nucleotides spaced at a distance so nearly equal to that of the long succession of amino-acid residues in a fully extended polypeptide. Rather is it a stimulating thought that probably the interplay of proteins and nucleic acids in the chromosomes is largely based on this very fact, and that some critical stage in mitosis, involving elongation of the protein chains, is realized in close co-operation with the dominating period of the interacting nucleotides.

We should like to express our indebtedness to Prof. Hammarsten and Dr. Caspersson of the Caroline

Institute for preparing for us the experimental material and for biochemical data.

X-ray examination of other nucleic acids and polynucleotides is in progress.

Structure of Metals

IN the note by Dr. A. Muller[1] with the above title, the scatter of spots in high-dispersion X-ray photographs was interpreted as indicating variations in lattice constant of individual crystals of the order of 1/1000 to 1/2000.

Prof. W. L. Bragg and H. Lipson[2] afterwards advanced the tentative explanation of the effects observed by Müller without making the deduction that the lattice constant varies. The scatter of spots in stationary photographs deduced from the effect shown by Prof. Bragg and Lipson is equivalent to a $\Delta d/d$ value of 1/2000 approximately, for l equal to 10^{-4} cm.

There are two further effects which can give rise to scatter of spots from grains of identical lattice constant. (1) A purely geometrical effect due to the finite convergency of the X-ray beam. (2) The fact that the $K\alpha$ lines have a finite width. The first effect, the purely geometrical effect, can give rise to an angular scatter of spots which for a given constant diameter of pinhole or diaphragm becomes less as the specimen to film distance increases, provided a focusing technique is utilized; for example, pinhole, diffraction line and specimen surface lie on the circumference of the same circle.

If a reference sphere is drawn, it is easily seen that a reflection is possible provided the normal to the set of planes giving the reflection lies within a band which is determined by the maximum angle of convergence of the incident X-ray beam subtended at the specimen surface. Furthermore, the reflection spots themselves can be within a band of similar angular width. The angular width of this band, $\Delta\omega$, or what is the same thing, the possible scatter of the reflection spots from crystals of identical lattice constant, is given by

$$\Delta\omega = \frac{\text{diameter of pinhole}}{\text{specimen-diaphragm distance.}}$$

Such a scatter might erroneously be taken as arising from a variation in lattice constant which for normal cameras of 5–10 cm. film-specimen distance can amount to 1 part in 1000 to 1 part in 2000.

Dr. Müller has kindly informed me that his high dispersion photographs were taken at 30 cm. with a 0·3 mm. pinhole. The purely geometrical scatter accounts only for a variation $\Delta d/d = 1/20,000$ approximately and does not explain Muller's result.

The second effect, the more important effect, is that due to the finite width of the $K\alpha$ lines usually used; it does not depend on the geometry of the camera system, though it must be considered in conjunction with the geometric effect in determining the conditions in which α_1 and α_2 reflections may intermingle.

Values for the half value width $\Delta\lambda$ of the K lines of copper, iron and cobalt taken from Compton and Allison[3] are as follows:

Full width at half max. of $K\alpha$ lines

Element	Line	Wave-length in X.U.	$\Delta\lambda$ in X.U.	$\Delta\lambda/\lambda$
Iron	$K\alpha_2$	1936	1·18	1/2000 approx.
	$K\alpha_1$	1932	1·02	,,
Cobalt	$K\alpha_2$	1789	0·95	,,
	$K\alpha_1$	1785	0·82	,,
Copper	$K\alpha_2$	1541	0·77	,,
	$K\alpha_1$	1537	0·58	,,

This definite half-value width would account for variations in angular scatter of spots from crystals of identical lattice spacing equivalent to $\Delta d/d = 1/2000$ as an upper limit, whilst since the half-value width is purely an arbitrary method of estimating line width, spots could occur possibly even down to $\Delta d/d = 1/1000$.

It is of special importance to take these effects into account when using rotating or oscillating film back reflection methods of determining lattice constants, as in internal stress measurements; that is, one must average over a large number of spots, otherwise serious errors in lattice constant and in internal stresses deduced will result.

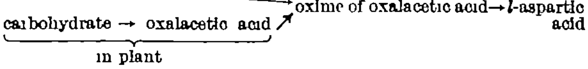
Biological Synthesis of Amino Acids from Atmospheric Nitrogen

SYMBIOTIC nitrogen fixation in leguminous root nodules proceeds, according to our conception, in the following manner:



N₂→ hydroxylamine
carbohydrate → oxalacetic acid
in plant
oxime of oxalacetic acid → l-aspartic acid

This conception is based, in the first place, on the investigation of excreted nitrogen compounds from the root nodules. In extreme cases up to 80 per cent of the total fixed nitrogen is excreted into the medium from the root nodules during the growth of the pea. This nitrogen is, as regards a small part, oxime-nitrogen (usually 1–2 per cent of the total nitrogen) but mainly amino nitrogen, belonging to l-aspartic acid and to its decomposition product β-alanine (not to lysine, as we first assumed). As the legume bacteria decarboxylate l-aspartic acid forming β-alanine, l-aspartic acid is the first amino acid excreted[1]. Its excretion from young nodules in large amounts proves that it is formed in nitrogen fixation as a primary amino acid, from which other amino acids are then formed.

In investigating the further transformation of l-aspartic acid in the host plant, it has been noted that if l-aspartic acid and, for example, pyruvic acid, are added to the mass of crushed pea plants, the amino group is transferred from aspartic acid to pyruvic acid, whereby α-alanine is formed, thus:

l-aspartic acid + α-keto acid → oxalacetic acid + α-amino acid.

In three hours the reaction is already far developed. The alanine was determined by extracting it from the reaction mixture with butyl alcohol and thereupon oxidizing it with ninhydrin to acetaldehyde. The transfer of amino group to α-keto acids in the plant is similar to that shown by Braunstein and Kritzman[2] in animal tissues.

The formation of aspartic acid as the only primary amino acid in nitrogen fixation is surprising. The dicarbonic acids of 4-carbon group thus attain a central position in the synthesis of amino acids. Oxalacetic acid which, according to our theory, is the acceptor to hydroxylamine, is found in considerable quantities both in pea plants and in red clover, from which we have up to the present determined it. Since the hydroxylamine reacts with the oxalacetic acid already in very dilute solutions almost immediately, it is clear that free hydroxylamine cannot be detected in the root nodules. The isolation of the oxime indicates, however, the course of the reaction. The oxime isolated as an excretion product, precipitates according to Foreman and thus apparently is the oxime of oxalacetic acid.

The reason why the hydroxylamine in the nodules reacts only with oxalacetic acid and not with other aldehydes or ketones is that the reaction with oxalacetic acid occurs at a much higher rate than with other keto acids investigated by us. In neutral solutions, each containing 0·2 millimols of oxalacetic acid, ketoglutaric acid, or pyruvic acid as sodium salts, the rate of reaction of hydroxylamine with oxalacetic acid was about seven times greater than with ketoglutaric acid and about fourteen times greater than with pyruvic acid. No reaction can be observed with glucose and fructose in such dilute solutions during 2 minutes' experiment time.

The Most Probable Place of Location of the Genes in the Chromonemata

GENETIC investigations during the last three decades have supplied evidence that the genes are located linearly in the chromosomes. Cytological studies of the meiotic prophases showed that the chromonemata are differentiated in length, consisting of chromomeres. Cytological studies on the salivary gland chromosomes in many insects and especially in *Drosophila* disclosed a discoid structure of the chromosomes. "From the differential staining behaviour of these chromatin disks one can conclude that they are or contain chemical compounds of diverse nature"[1].

The differentiation of the chromonemata in the somatic cells in plants has offered somewhat greater difficulties. Recently, I succeeded in preparing preparations from *Triticum Timopheevi* root tips in which the chromomere structure of the chromatids during the late prophases and early metaphases was very distinctly disclosed. In a number of chromatids the chromomeres were much more closely arranged at the distal ends of the chromosomes, thus forming the heterochromatic regions[2]. In *Drosophila* the heterochromatic regions are poor or devoid of genes[3,4]; therefore they are called inert regions.

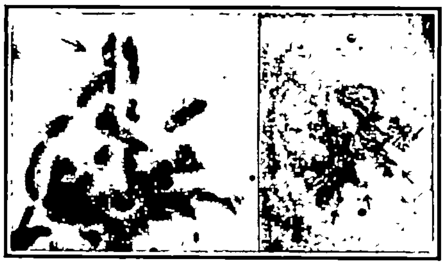

Fig. 1.

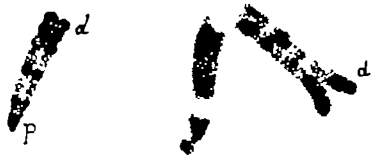
PHOTOMICROGRAPHS FROM THE ROOT TIP CELLS OF *Triticum Timopheevi*. CHROMOMERES IN THE CHROMATIDS ARE MARKED.

If we may use the differential staining for diagnosis of heterochromatic (inert) regions, as we seem to have good reasons for doing, we can conclude that heterochromatic regions are rich in chromomeres, but poor in interchromomeric substances. If the genes were located in the chromomeres, the heterochromatic regions should be active, but since they are inert, the genes should be located then between the chromomeres.



(a) (b)

Fig. 2.

(*a*) THE LONGER ARM OF ONE CHROMOSOME; *d*-DISTAL AND *p*-PROXIMAL ENDS. (*b*) A WHOLE CHROMOSOME. DARKER REGIONS CAN OFTEN BE SEEN AT THE DISTAL ENDS; THEY ARE USUALLY DUE TO CLOSER ARRANGEMENT OF THE CHROMOMERES, THOUGH SOMETIMES THESE CHROMOMERES ARE SOMEWHAT LARGER.

Function of the 'Fossula spongiosa' or Spongy Furrow in Reduviidæ (Rhynchota)

So far as is known, the majority of Reduviidæ are predators of other insects, and consequently their anterior legs in particular, with the median legs, are of utmost importance in assisting them to capture their prey, especially when it is an active insect. But, in spite of their predaceous habits, it is perhaps remarkable that few Reduviidæ, with the exception of the sub-family Emesinæ and the Old World genera, *Irantha*, *Polydidus* and *Scipinia*, possess anterior legs of the raptorial type.

Very considerable diversity of structure, however, is exhibited by the anterior tibiæ of various genera, which may be thickened apically, dilated for the greater part of their length, provided with single or multiple spines, or may be of a simple type. In many species the anterior tibiæ and sometimes the median tibiæ also are provided, on the inner surface, with a sulcate or flat area of very dense short setæ. This area may be short or may cover at least half the tibiæ of the anterior legs, but is always short on the median tibiæ.

This area is referred to as the 'fossula spongiosa' or 'spongy furrow', a term which, however, is not entirely accurate for, as stated in the previous paragraph, it is not always sulcate, but is more or less flat and, in fact, may have a narrow raised area throughout longitudinally.

The origin of the term 'spongy furrow' is obviously due to the fact that the examination of most Reduviidæ has been restricted to dried specimens, and it is when they are in this condition that the structure on the tibiæ appears sulcate. In some species the 'spongy' area on the anterior tibiæ is produced, and extends to about the middle of the tarsus.

In the blood-sucking Reduviid *Rhodnius prolixus* Stål, the 'spongy furrow', which is small and present on the anterior and median tibiæ, has been considered to be a climbing organ by Gillett and Wigglesworth[1], who based their conclusions on the fact that the adult *Rhodnius* were able to climb the glass walls of the jars in which they were confined. Larval *Rhodnius*, they stated, were unable to do so. According to these investigators, in the living *Rhodnius* the organ is "an elastic sac distended with fluid". In dried specimens, however, it is shrunken and depressed.

Now, the localities which this species of *Rhodnius* inhabit are roughly constructed mud and thatch huts, an environment in which they are able to move about freely without the aid of a specially adapted climbing organ. The absence of the 'pad' from the tibiæ of larval *Rhodnius*, which would require it equally as would the adults, if it were a climbing organ, since they inhabit the same localities, indicates that the structure is not for that purpose. Those Reduviids to which a climbing organ might be advantageous, such as the Malaysian genera *Ectinoderus* and *Amulius*, frequenters of trees up which they climb, possess tibiæ devoid of a 'spongy furrow'; and furthermore, it is noteworthy that they cover the anterior pair thickly with resin to aid them to capture their prey, which consists largely of small bees of the genus *Melipona*. A 'spongy furrow', if it were present, would in this case be rendered ineffective as a climbing organ by the resinous covering.

Some other Old World genera, namely, *Sycanus* and *Cosmolestes*, as far as observation goes, prey principally on the relatively sluggish larvæ of Lepidoptera, to find which they are obliged to climb about on plants. From these genera the spongy furrow is absent.

In my opinion, it would seem therefore that the function of the 'spongy furrow' is not for the purpose of assisting the insect to climb but to enhance the gripping power of the tibiæ when the prey is captured. Further investigations may show that the degree of development of the furrow is related to the degree of toxicity of the saliva injected into the prey when captured, higher gripping qualities being combined with a less toxic or less rapidly acting fluid.

It should also be pointed out that a feeble development of the 'spongy furrow' is common when the anterior femora and tibiæ are provided with spines. In the case of *Rhodnius*, the 'spongy furrow' should probably be considered a vestigial organ, as it would be of no assistance to the bug when attacking man.

Modern Studies of the Foraminifera

MAY I suggest that an opinion may be arrived at regarding modern studies of the Foraminifera other than that given in NATURE by Mr. E. Heron-Allen ?[1]

Mr. Heron-Allen deplores the amount of literature published on the Foraminifera of late years, and of the number of families, genera and species described therein as new. I cannot see any escape from this result when an increased number of persons studies any group, in this case on account of its fairly recently recognized economic importance, the Foraminifera now being largely used as horizon markers in oilfield geology. Of the fact that it is often not possible to identify one's specimens with described material, there may be instanced the considerable number of forms described as new in some fifty valuable monographs and papers on the group by Mr. Heron-Allen himself, usually in collaboration with Mr. Arthur Earland.

I cannot appreciate that this is anything extraordinary, or that it differs from the modern tendency in other branches of zoology. For example, the number of described insects is colossal, and the estimated number yet undescribed is vaster still. Why, then, should one be aghast that detailed work on the Foraminifera (which often swarm in myriads), of areas and geological formations in which they may have been hitherto completely unknown, should yield many new forms ? The point that new names are often given unnecessarily is as old as the subject; it may be worse now, partly on account of the difficulty of keeping pace with the new literature, particularly when papers are written in places where adequate access to it is impossible.

Mr. Heron-Allen referred (136, 132; 1935) to "the great *scientific* Foraminiferists" of old, implying that the work of modern students of the group is not scientific. As a general statement neither claim is acceptable. It is clearly impossible to make an analysis of the literature to decide what is "scientific" and what is not, and the selection of particular modern work to illustrate the point might be invidious. But in my opinion, and without denying the poor quality of some, there is much work of the post-War period that is fully up to the standard of any of that of Mr. Heron-Allen's 'giants'.

On the other side of the picture, two of Mr. Heron-Allen's examples of the "great *scientific* Foraminiferists" are Terquem and Haeusler. Terquem's fourteen monographs on the Jurassic Foraminifera form one of the most appalling examples of species-making in the whole of the literature. In these, according to my notes, he proposed no fewer than 682 new trivial names, very many of which appear to be redundant. Haeusler, on the contrary, in his sixteen monographs and papers, also on the Jurassic Foraminifera (omitting his first paper, which his later work did not confirm), proposed only some 34 new names all told, preferring to identify many of his specimens with forms described from Tertiary and Recent material.

Were the works of these two authors to be held up as models, the future of the systematic study of the group would be black indeed.

It is concluded that modern work on the Foraminifera is very like that of those who are now dead: it is either good, bad or indifferent. The difficulty is that there is more of it to cope with.

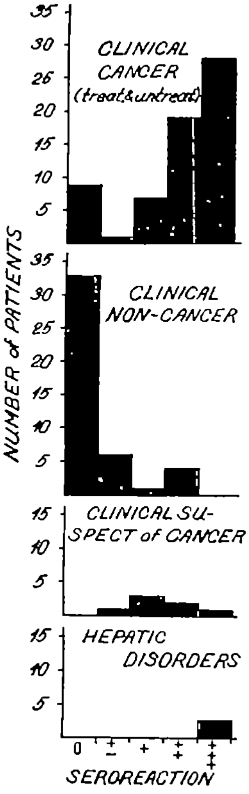
The Prague Sero Reactions for Cancer

Waldschmidt-Leitz[1], Brdička[1,2] and collaborators have recently published preliminary notes on sero reactions for cancer; they measured the activation deactivation of certain enzymatic processes or examined by the polarograph the reactions of certain catalytic processes after addition of serum or peptidized serum from men or animals with or without cancer, and ascribed the difference in action of cancer sera and non-cancer sera to differences in concentration of active S—S groups.



After a visit (by H.) to the institutes in Prague, where the workers in question kindly demonstrated the technique and material, we have carried out the sero reactions according to Brdička's polarographic methods[2,3] on sera from 118 patients: 44 without clinical symptoms of cancer, 7 with symptoms suspect of cancer (2 rough hypertrophia prostatæ with 'lumbago'), 1 anæmia simplex with achylia gastrica (61 years old), 1 cardiospasm, 1 agglutinatio vaginæ with fluor (72 years old), 1 cancer uteri incipiens (?), and 1 chronic icterus, suspect of cancer pancreatis (80 years old); 64 with clinically manifest cancer, and 3 with parenchymatous hepatic disorders (1 intoxication with sanocrysin, 1 intoxication with iodine and 1 with statis hepatis e morbu cordis incompensata).

For the reactions we have used two preparations:

(a) To 5 ml. of 0·05 *N* hydrochloric acid containing 5 mgm. pepsin, 0·2 ml. serum was added. The mixture was incubated at 40° C. for 20 minutes and then 0·2 ml. was withdrawn and added to 10 ml. of 0·0016 *N* cobaltous chloride in 0·2 *M* ammonium chloride – ammonia buffer (equal parts). The polarographic curve of this mixture was registered[2].

(b) To 1 ml. of 0·1 *N* potassium hydroxide 0·4 ml. serum was added; the mixture was kept at room temperature for 20 minutes, 1 ml. of a 20 per cent solution of sulphosalicylic acid was added and the mixture filtered; 0·6 ml. of the filtrate was added to 5 ml. of the following solution (to 150 ml. *N* ammonia + 50 ml. *N* ammonium chloride + 700 ml. water was added 100 ml. 0·03 *N* hexamine cobaltic chloride). The polarographic curve of the mixture was registered[3].

Every day a sample from a clinically non-cancer patient was used as a standard. The galvanometer sensitivity was 1 : 200; the strength of reaction was taken as the difference of curve height in millimetres between standard and unknown serum according to the following scheme:

Reaction 0 : lowest = 0 mm. or both = 1 mm.
± : „ = 1 „ „ = 2 „
+ + : „ = 2 „ „ < 6 „
+ + :6> „ = 3 „ and highest ⩾ 6 mm.
+ + + : „ ⩾ 6 „ „ „ ⩾ 10 „

The results are given in the accompanying block diagram, which shows that the majority of the non-cancer sera fall in the negative group, while the majority of the cancer sera + the 'hepatic' sera fall in the strongly positive groups. *The difference is unquestionable.*

Our present technique and material do not allow statistical treatment or conclusions regarding the future diagnostic value of the reactions. Further investigations are being undertaken for this purpose.

We wish to thank Profs. Waldschmidt-Leitz, Heyrovský, Brdička, Knaus and Novak in Prague for kind personal communications.

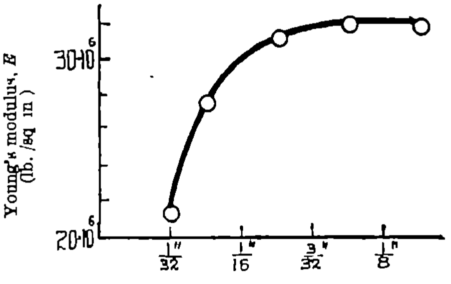
Value of Young's Modulus for Nickel Wire as Influenced by the Diameter

MAKING use of the electro-magnetic method for measuring the frequency of longitudinal vibrations



Diameter.

as described in a previous note[1], tests for Young's modulus have been made on pure annealed nickel wires of various diameters in the "as received" condition. The results are shown in the accompanying graph, and it will be seen that for wires of diameter less than about 3/32 in. the value of the modulus rapidly decreases with the diameter.

Tests made on copper-plated nickel wires after heating in hydrogen to a condition of maximum magnetic permeability give a similar curve for Young's modulus, but the values are in general somewhat lower.

Reflecting Power of Ultra-pure Aluminium

Electrolytic polishing of metallic surfaces, which has been studied by one of us[1], does not modify the metal structure. On the contrary, it is known that classical methods of polishing greatly alter the superficial crystalline structure.

Recent work with copper has shown that surfaces polished by the electrolytic process give values of the optical constants which are reproducible, whereas this is far from being the case when surfaces of copper are prepared by mechanical polishing or by evaporation in vacuum[2].

We give here the first results of an optical study of aluminium surfaces prepared from metal 99·998 per cent pure. An aluminium block is laminated to 7 mm. Little strips are then cut (of about 2·3 cm.^{2}) which are polished with emery paper (0–04), covered with paraffin. The metal is recrystallized by heat treatment and the polish is finished on felt disks covered with a suspension of fine alumina (6 and 12 hours). Many of these surfaces were subjected to electrolytic polishing[3] for a time sufficient to allow dissolution of the superficial pellicule formed during the final stage of the polishing. The other surfaces were finally polished on cloth disks covered with alumina (12 hours).

The reflecting powers of these two types of surfaces have been measured by the photo-electric method of Orsel[4] modified by one of us[5]. The filtered light of a tungsten strip lamp is used ($\lambda = 4500$ A.). The seven surfaces polished electrolytically have the same reflecting power within the experimental error (about 1 per cent), and the reflecting power is remarkably constant at every point of each surface. It is observed that the size of the metallic crystallites conditioned by the previous heat treatment has no influence; moreover, the surfaces even after many days exposure to atmospheric conditions, but protected against dust, do not show any alteration. Table 1 gives the results. The reflecting power is given by comparison with a polished surface of galena taken as a standard.

Table 1.

Number of sample		3*	5**	7**	8**	15**	17**	18†
Reflecting power	24 hours after polishing	2·23	2·23	2·24	2·24	2·25	2·25	2·24
	72 ,, ,, ,,	—	2·25					
	96 ,, ,, ,,	2·24	2·24					
	120 ,, ,, ,,	—	2·26	—	—	—	—	2·25

* Annealed for 20 hours at about 620° C
** ,, ,, 68 ,, ,, 620° C.
† ,, ,, 30 seconds at 350° C.

Table 2 gives the values of the reflecting powers of surfaces mechanically polished. These values are obtained immediately after polishing and they can be compared with the reflecting power of surfaces polished electrolytically.

Table 2.

Number of sample	1**	2*	4**	6**	9**
Reflecting power at different regions of each surface	0·61 0·57	0·68 0·66 0·65	0·60 0·62	0·73 0·68 0·69	0·67 0·68

* Annealed for 20 hours at about 620° C.
** ,, ,, 30 seconds at 350° C.

This table shows that the reflecting power varies notably from one surface to the other, and that even for a given surface it varies from point to point.

We conclude that ultra-pure aluminium surfaces polished electrolytically have a reflecting power well defined and reproducible. This suggests the use of such surfaces as optical standards. Moreover, such surfaces have a reflecting power greater than that of surfaces otherwise prepared. These observations show that this technique will be useful for the micrographic study of the crystalline structure of aluminium.

A Whale Story

Many readers of Nature may have heard an incredible story, broadcast by the B.B.C., Regional, on January 11, 1938, in a series of talks called "Strange to Relate", about an alleged James Bartley of the *Star of the East* having been swallowed by a sperm whale and recovered alive from its stomach some hours after. The intelligence of readers of Nature is such that I expect and hope few if any gave credence to the story, but of the thousands who heard it I fear many must have thought, "It must be true, or the B.B.C. would not broadcast it".

I first came across this story in "Sixty-Three Years of Engineering" by the late Sir Francis Fox, and in reviewing that book for the *Journal of the Society of Engineers* (October–December 1925, pp. x–xiv) I made it amply clear from internal evidence that the story would not hold water. Afterwards, a published letter was found from the widow of the captain of the *Star of the East*, in which she stated that she was on board that vessel at the time of the alleged event, and that there was not a word of truth in it.

Through Dr. Julian Huxley, a member of the Talks Advisory Committee, I was able to bring the facts before the B.B.C. with the result that it was arranged to explain that the story was completely untrue. The correction was made on March 7, but few people who heard it would have recognized it as related to the dramatic story originally broadcast. Because there must be many thousands who heard the story but missed its correction, it seems worth while to record the facts in these columns.

Albino Frogs

Some years ago, Dr. Nellie B. Eales wrote concerning records of albino frogs[1]. It will be of interest to zoologists to know that on March 28, 1938, a schoolboy found a mass of white spawn in a brook at Coley, Reading, Berkshire. The brook contained many other masses of normal spawn.

The appearance of the spawn was that of clear jelly with milk-white ova. The boy reported the matter to his master, who retained some spawn, and the rest was handed to the Reading Museum by the finder. Except for a small quantity passed to the University of Reading, we have the residue here.

To-day (April 5), many of the eggs have developed into white tadpoles with distinctly pigmented eyes, and slight pigmentation is developing rapidly in the dorso-lateral region. We shall endeavour to rear these specimens, but I shall be happy to pass specimens to any zoologist for scientific work.

It is assumed that one parent was probably a true albino, as in the case of the Woodcote specimens in 1933.

Points from Foregoing Letters

Observations of solar activity made at Canberra, Australia, by A. J. Higgs and R. G. Giovanelli, with a spectrohelioscope and indirectly from a study of conditions in the ionosphere, have related recently observed auroras and magnetic storms to definite periods of activity. The interval, 38 hr., between the solar eruption and the auroral display of January 25–26 appears to be longer than usual (26 hr.).

H. C. Corben points out that, from Eddington's relation between the mass of the proton and that of the electron, the existence of a scalar particle of mass 135·9 can be deduced and this, combined with a positive or a negative electrical charge, will account for the recent observations which indicate that particles of about this mass exist in cosmic rays.

Dr. W. T. Astbury and Miss Florence Bell conclude from an X-ray examination of the sodium salt of thymonucleic acid that the molecule consists of a succession of some 2,000 nucleotides, standing out perpendicularly to the long axis, and spaced at a distance ($3{\cdot}3_4$ A.) almost exactly equal to the spacing of the succession of amino-acid residues in a fully extended polypeptide. The probable significance of these findings for chromosome structure and behaviour is pointed out.

R. A. Stephen points out that in addition to the purely optical effect as described by Prof. W. L. Bragg and H. Lipson, there are two further effects which may give rise to angular scatter of spots in high-dispersion X-ray photographs. (1) A purely geometric effect due to the finite size or lack of parallelism of the incident X-ray beam. (2) An effect due to the finite width of the lines of the $K\alpha$ doublet. The first effect is insufficient to explain the scatter observed by Müller but the second effect gives results of the right order.

Prof. A. I. Virtanen and T. Laine find that if *l*-aspartic acid and pyruvic acid are added to crushed pea plants, the amino group is transferred from aspartic to pyruvic acid with formation of α-alanine. The authors consider that aspartic acid is the only primary amino-acid synthesized during the fixation of nitrogen and discuss the manner of its formation.

Prof. D. Kostoff submits photomicrographs of chromosomes in the root tip cells of *Triticum Timopheevi* showing differential staining—the distal ends being darker—presumably owing to a greater number of chromomeres. Since the heterochromatic regions have been found to be genetically inert (in the fruit-fly), the author considers that the genes are probably located between the chromomeres.

The spongy furrow on the inner surface of the anterior tibiæ of certain species of Reduviid bugs, which are predators of other insects, serve the purpose of enhancing the gripping power of the tibiæ when the prey is captured, according to N. C. E. Miller. They do not apparently help in climbing, as suggested by previous writers.

Results obtained with the sero-reaction of cancer described by Waldschmidt-Leitz and Brdička are given by F. Bergh, Dr. O. M. Henriques and J. Schousboe. They have obtained positive reactions with the sera of most cancerous patients and with those suffering from certain diseases of the liver, whilst non-cancerous individuals give predominantly negative results. The difference, they state, is unquestionable, but the statistical evidence is insufficient, as yet, to prove the value of the reaction in diagnosis.

A graph submitted by Dr. T. F. Wall shows that for nickel wires of diameter less than about 3/32 in. the value of the Young's modulus (determined by the electromagnetic method for measuring longitudinal vibrations) decreases with the diameter.

Drs. P. Jacquet and L. Capdecomme have studied the reflecting power of ultra-pure aluminium surfaces polished either by the classical mechanical process or by the new electrolytic method. The latter does not change the superficial crystalline structure and gives values very nearly the same at all points of several samples, whereas surfaces polished mechanically show reflecting power variable from point to point and always smaller than that observed after electrolytic polishing.

Research Items

Survivals and Regressions in Javanese Culture

What might be termed a cultural 'backwash' is described by Dr. F. Stutterheim of Batavia in an account of a 'neo-megalith' in Old Batavia (*Bull. Raffles Mus.*, Singapore, 1937, Ser. B, 1, 3). It has been pointed out frequently that many of the so-called Hindu antiquities in Java are nothing but Hinduized versions of pre-Hinduistic holy sites. This is especially noted of monuments found high up in the hills and consisting of terraces and altars in the open. Thus Chandi Sukuh, on the slopes of Mount Lawu, immediately betrays its pre-Hinduistic origin by its lay-out in terraces, though its ornament, especially its reliefs and figures, show a Hinduized style. The main altar, a truncated pyramid, strongly suggests Polynesia and ancestor worship. In Java, such features are usually called "Polynesian" or "old-indigenous". In all instances, the evidence of Hindu art and culture in ornament and relief belongs in style to the latest period of Hinduism in Java. We may, therefore, assume that it represents the ultimate penetration of Hinduistic conceptions, valid for centuries in the plains, into the remote hill districts, where indigenous ideas had lingered on. It is known that the spread of Hinduism in Java was a very gradual process. At the same time, these monuments illustrate the persistence of the indigenous culture. A stronger proof of the persistence of these indigenous beliefs would be the occurrence of a Hindu or Mohammedan sanctuary transformed into a 'megalithic' or indigenous object of veneration. An example of such a transformation appears to be afforded by a recently observed mound covered with stones of different kinds in Kampong Traté of Old Batavia. It was topped by an upright stone of somewhat conical shape, which turned out to be smoothed river stone. Among the stones covering the mound were bricks, and three pairs of Mohammedan tombstones. These removed all doubt but that the original purpose of the mound had been that of Mohammedan burial, but that, probably at about 1700, it had been transformed into a holy place. At the foot of one stone were traces of flowers and incense. The smooth oblong cylindrical stones assembled here are strongly reminiscent of *gandik*'s stone rollers for crushing medicinal ingredients, which are considered all over the Archipelago to have strong magical powers.

Amphibian Mesectoderm

Rana japonica has been utilized by M. Ishikawa (*Mem. Coll. Sci. Kyoto*, 12, Oct. 1937) for investigating the origin and role of the mesectoderm during development and in particular with reference to cartilage formation. The mesectoderm makes its appearance in the early neurula stage. It takes no part in the formation of the neural tube as in Urodeles and migrates solely by the proliferation of its own cells, receiving no contribution from the dorsal part of the neural tube. Normally it migrates ventrally over the mesentoderm in the branchial region, and gives rise to the cartilages of the visceral arches. If it is transplanted into the brain cavity or into the somatic mesentoderm of the side of the body it also produces cartilage. Cartilage is also formed if it is transplanted into the mesenchyme of *Hynobius nebulosus*. Mesentoderm appears to be important but not essential to the production of cartilage by the mesectoderm. By the time of the closure of the neural folds, the mesectoderm is segregated into mandibular, hyoid and branchial units, and an extirpation of any one of them results in the lack of or incomplete development of the corresponding cartilage. The auditory capsule is derived from cranial mesentoderm and not from the mesectoderm.

Testing Insecticides and Fungicides

The constant production of new materials for the control of pests and diseases of fruit plantations calls for rapid laboratory methods for testing their efficiency. A procedure adopted at East Malling for testing fungicides has recently been described by H. B. S. Montgomery and M. H. Moore, and methods for insecticides are given by W. Steer (*J. Pom. and Hort. Sci.*, 15, No. 4; 1938). In the former method, 0·015 c.c. quantities of fungicide solution are spread uniformly over circular areas marked on glass slides and allowed to evaporate. 0·04 c.c. of an aqueous suspension of conidia of *Venturia inaequalis* is similarly applied and the slides stored in a saturated atmosphere at 21° C. Counts of germinations are then made at intervals. When desired, the spray deposit may be washed with water to simulate rainfall before applying the fungus. Methods of growing *V. inaequalis* in pure culture, and of assessing the results of treatment are described and the effects of tests with copper- and sulphur-containing materials discussed. Amongst organic substances tried, tetramethylthiuram disulphide was found to be highly fungicidal. The second paper describes the use of eggs of *Orgyia antiqua* L., *Operophtera brumata* L., *Aphis pomi* de G. and *Oligonychus ulmi* Koch, for testing ovicides. *O. antiqua* has also been used for contact and stomach poisons. Females of *O. brumata* are collected in orchards and induced to lay eggs on twigs in special cages. The twigs are then dipped in the insecticide, the toxicity of which is afterwards assessed from counts of hatched and unhatched eggs. Spray materials that show promise are applied to single branches of fruit trees to ascertain any damaging effect on the foliage before extensive field trials are begun.

Cytogenetics of Rice

The importance of rice as a world cereal has led to much recent work on the genetics of this plant. Two papers by Dr. S. Ramanujam (*J. Genetics*, 35, No. 2) deal mainly with triploids and their offspring. A sterile autotriploid mutant, which had thicker stems, broader leaves and larger spikelets, appeared in 1933. When grown with diploids, after being vegetatively multiplied, it gave a progeny of 60 plants, ten of which turned yellow and died as seedlings. These plants were derived from 150 good seeds which had been obtained from nearly 41,000 spikelets. A cytological study of these plants showed three nucleoli in somatic telophases, as against two in the diploid. Also three bivalents were attached to the large nucleolus in the pollen mother cells. The view that rice is a secondary tetraploid with basic number 5 chromosomes, including two pairs of satellited chromosomes, is confirmed. Some rice varieties, however, have but one pair of satellites. It is shown how this condition can arise. In the triploid progeny the chromosome numbers ranged from 24 to 30, with decreasing size of plant according to the number of extra chromosomes. *Oryza sativa* × *O. officinalis* finally gave a single seed which germinated and produced an intermediate sterile hybrid with $2n = 24$ as in both parents. Vegetatively multiplied and grown among *O. sativa* plants, ten seeds were obtained, six of which germinated and all proved to be triploid. The original hybrid showed failure of the chromosomes to pair in meiosis, but in certain cells they all divide in both mitoses, presumably producing diploid gametes which are alone functional. The $3n$ offspring showed extremely abnormal meiosis, with frequent coalescence and degeneration of pollen mother cells.

Stem Rot of the Oil Palm

The Department of Agriculture, Straits Settlements and F.M.S., has published as No. 21 in the Scientific Series, 1937, a paper upon the stem-rot of the oil palm by A. Thompson, senior plant pathologist. Observations made on a group of 720 oil palms growing on a quartzite soil with a sand-pan situated at various depths below the surface show that a form of stem-rot disease is caused by the fungus, *Fomes noxius*, and that the other fungi present in decaying leaf bases are relatively harmless. *F. noxius* is a facultative parasite which, on penetrating into the stem tissue via the leaf bases, normally extends laterally round the stem and horizontally in the outer stem tissue during the first years following infection; inward penetration then proceeds more rapidly but palms are rarely killed until two or three years after infection. The disease is only serious in areas of deep peat or in quartzite valley soils with sand beds approaching the surface. Control measures are discussed, and it is shown that burial of infected palms is not likely to be dangerous as *F. noxius* does not attack the roots.

Directional Recording of Atmospherics

One of the investigations of fundamental importance carried out by the Radio Research Board in Great Britain comprises the study of the nature and origin of the atmospherics encountered in radio reception. For several years past, radio direction-finding methods have been employed to locate the sources of atmospherics, and the results obtained have been compared with the position of storm areas obtained from meteorological data. A paper recently published (*J. Inst. Elec. Eng.*, March) by F. E. Lutkin under the title "Directional Recording of Radio Atmospherics" presents the latest results of this research work. These results have an enhanced value over those previously communicated in so far as they were obtained with an improved type of instrument, which is described in some detail. The directional receiver employed accepts atmospherics only over a sector of 20° unambiguously, and it is arranged to record the direction of arrival of these transient impulses continuously throughout the day. The minimum field strength required to produce a recordable deflection on the instrument is about 0·25 millivolt per metre. The paper deals with the records obtained in Great Britain during the years 1930–33. It is shown that most of the disturbances arrive from the west or south-west, but during summer afternoons sources to the east and south-east are productive; together with storms of a purely local character. It appears from this investigation that the majority of the atmospherics producing disturbance in long-wave radio reception in Great Britain are generated in distant regions of thunderstorm activity. They suffer variable attenuation in propagation, depending upon conditions in the ionosphere over the path along which they travel. In consequence the American sources supply the majority of atmospherics with a field strength exceeding 1 millivolt per metre in England. Summer afternoon and evening sources lie in the thunderstorms of Europe, but American sources always predominate during the night and early morning.

Principles of Violin Construction

In the issue of the *Journal of the Franklin Institute* of March, Mr. P. Jarnak of the Polytechnic, Copenhagen, gives the principal results of the investigations of the violin, viola and 'cello which, with the help of a grant from the Oersted Foundation and the co-operation of the Bell Telephone Co., he has carried out with a view of reviving an art lost soon after the death of Stradivarius in 1737. By electrical amplification and record of the sounds produced by some of the best old and modern instruments he has determined the relative amplitudes of the fundamentals and harmonics which give the most beautiful tones, and for these the body of the instrument must be capable of acting as resonator. The heavy wood back is, the author considers, divided into two coupled resonators by the sound post, the light wood front into four by the bass bar and bridge and these six resonators must be capable of reinforcing the requisite notes. He shows on calculating their possible frequencies from their dimensions that in instruments of good tone they do this—in bad ones they do not. By altering the dimensions of the resonating parts he has improved the tones of poor instruments and has confirmed his theoretical work in a way which should lead to the possibility of producing instruments equal to those of the old masters.

Shape of Eros and its Light-Changes

Dr. A. C. D. Crommelin has recently issued a paper on the question of the remarkable changes of light to which Eros is liable, these changes having been detected at its second apparition in 1900–1 (*J. Brit. Astro. Assoc.*, **48**, 5, March 1938). Two theories were put forward to account for this phenomenon: (1) differences of albedo on different parts of its surface; (2) departure of its figure from a spherical form. The Johannesburg equatorial at the Union Observatory showed the planet elongated at the near approach in 1931, and it is certain that Eros is dumb-bell or sausage shaped, rotating about an axis perpendicular to its long diameter. The period of light-change is $2^h\ 38^m$, and if the shape is symmetrical this may be only half the rotation period. Jaschek, at Vienna, and other observers, have noted light-changes of much shorter period, and this suggests local irregularities of figure—a condition quite consistent with the fact that cohesion, not gravitation, is the main factor in controlling the form of Eros.

Plant Protection in the Soviet Union

By R. C. Rainey

In the course of a recent visit to some of the chief Russian entomological research centres, I had the opportunity of seeing something of the headquarters of the Soviet plant protection service, the All-Union Institute for Plant Protection, and also of seeing the Plant Protection Station for the Leningrad Province. In view of the attention which Russian agriculture has attracted in recent years—Vavilov states that the 1937 harvest has proved the largest in history—the following notes may be of general interest.

The more basic agricultural research in Russia is directed by the Lenin All-Union Academy of Agricultural Sciences in Moscow, controlling the work of half a dozen or more research institutes. One of these is the Institute for Plant Protection; another is the Institute of Plant Industry, which has its headquarters in the former Ministry of Agriculture building in the Ulitza Gerzena, Leningrad (Fig. 1), and is directed by Dr. N. I. Vavilov, vice-president of the Academy, whose world-wide investigations into the origins of cultivated plants are now well known, and for whose assistance during the present visit I am particularly grateful.

Fig. 2.

Laboratories of the Institute for Plant Protection, Elagin Ostrov, Leningrad.

VIZRa, the Institute for Plant Protection, has its administrative headquarters in the Ulitza Krasnaya in Leningrad, while most of the laboratories are housed in a small palace (Fig. 2), said to have been formerly the residence of Stolypin, Nicholas II's minister, on the Elagin Ostrov, an island in the Neva on the northern side of the city. The gardens occupying the remainder of the island now constitute the Kirov Park of Culture and Rest; a dance for factory workers was in progress in the former ballroom of the palace during one of my visits to the Institute. Something like fifty research workers, together with their assistants, are employed by VIZRa, which is subdivided into a number of sections dealing with ecology, biological control, chemical control, mechanization of control measures, pests of special crops such as grain and cotton, and so on; in the limited time available it was only possible to see a small proportion of the work in progress, even apart from the extensive field studies.

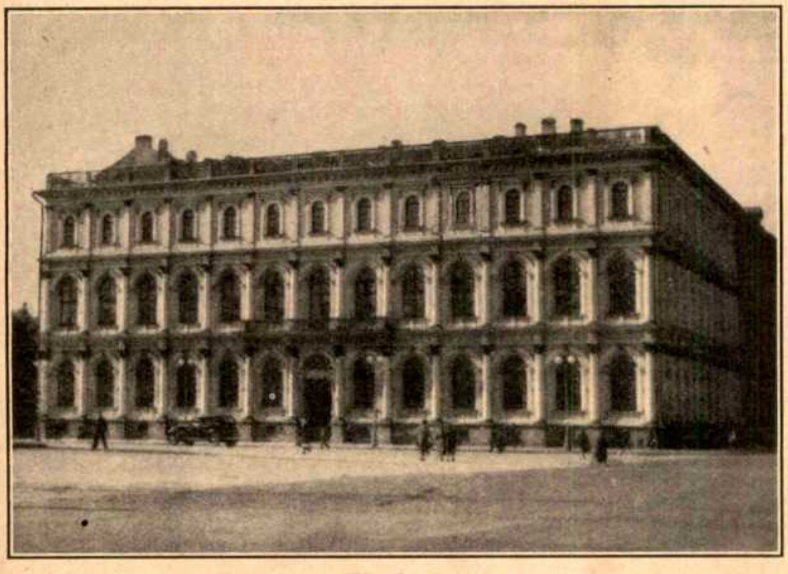

Fig. 1.

Institute of Plant Industry; Ulitza Gerzena, Leningrad.

Dr. J. I. Prinz and his collaborators are investigating problems of soil ecology, working chiefly with the chafer beetles *Melolontha melolontha* L. and *M. hippocastani* F., and with the wireworms *Agriotes obscurus* L., confined to the northern parts of the Union, and *Selatosomus latus* F., a more southern species. Considerable progress has been made in the difficult task of rearing these long-lived insects under controlled environmental conditions; *Melolontha*, for example, can now be reared without soil from the beginning of the second instar, and its life-cycle is completed in 10–12 months in the laboratory, as compared with four years or so in the field. The optimum conditions for oviposition and for the larval development of *Agriotes* have also been largely worked out.

Dr. I. A. Rubtzov's laboratory is primarily a methodological one, investigating methods of studying the various factors influencing insect numbers. Many of the methods used are those familiar in Great Britain, but they do not appear to be applied uncritically; for example, sulphuric acid and a number of metallic salts are no longer used in the control of humidity, as they are stated to have injurious effects on the experimental insects. Associated with Russian climatic conditions, temperatures down to −20° C. are used in cold-hardiness work. Some interesting work is in progress on the rearing of phytophagous insects such as plant-sucking bugs under conditions of controlled temperature and humidity; large double-walled thermostatically controlled greenhouses are available for the experimental plants. Rubtzov has also carried out important work in Siberia demonstrating phase variation in non-migratory grasshoppers essentially similar to, though less pronounced than, the phase differentiation in locusts.

The biological control section is directed by N. F. Meyer, who has carried out a considerable amount of survey and taxonomic work on the parasitic Hymenoptera, while V. P. Pospelov is in charge of investigations in insect microbiology.

In the chemical control section, which includes the laboratories of insect toxicology, oil emulsions, vegetable poisons, fumigants, and phytotoxicology, Dr. C. J. Bliss, the American statistician, has been working for the last two years on a contract with the Soviet Government; he has been carrying out a programme of theoretical and practical work on the application of statistical methods to entomological problems, with particular reference to the design of experiments for insecticide trials. A new type of spray testing apparatus, incorporating the ideas of Campbell and Tattersfield with modifications suggested by Bliss, and made by the Institute's technicians, has recently been supplied to several of the laboratories. A somewhat similar apparatus is used for laboratory trials of insecticidal dusts; leaves are dusted under controlled conditions in a special chamber, and standard disks of treated leaf are supplied to each insect. The concentration of dust on the leaves is determined by weighing similarly exposed cover-slips of known area on a microbalance; the amount of dust ingested is determined from the area of leaf eaten, found by mounting the partly eaten disks on squared paper. The method is of course applicable only to stomach poisons. The staff of the chemical control section, like other Soviet workers whose duties involve handling toxic materials, each receive a free extra milk allowance of half a litre daily.

The Plant Protection Station (STAZRA) for the Leningrad Province is directed by Prof. N. N. Bogdanov-Katkov, who also holds a teaching post in the Institute of Applied Zoology and Phytopathology, at which plant pathologists and entomologists are trained. A visit was also made to the field station at Peterhof, about twenty miles out of the city on the sea-coast near Peter the Great's palace. Research is carried on in addition to the advisory work, and recommendations concerning new control measures are circulated among the collective farms of the province. One such new control measure is the use of a naturally occurring hydrated ferrous phosphate to protect seed, particularly seed corn, from various stored products pests, particularly the flour mites *Tyroglyphus farinæ* DeG. and *Glycyphagus destructor* Schr., often associated with the predaceous mite *Cheyletus eruditus* Schr. The ferrous phosphate is found under the peat of the moors of Karelia and elsewhere at a depth of a foot or so; on air-drying, it falls to a fine blue powder which is used as a seed-dressing. It appears to act not as a poison but as a repellent, the mites dying after some weeks apparently from starvation.

The arsenicals generally used against orchard and vegetable pests are calcium arsenate and sodium arsenite and arsenate; the employment of lead arsenate is illegal, on account of the possibility of cumulative poisoning. The alkaloids aconitine and anabasine appear to be used to a considerable extent; another somewhat unfamiliar insecticide is chloric acid, used as a 1/10 per cent solution for the destruction of the eggs of the cabbage root-flies *Phorbia brassicæ* Bch. and *P. floralis* Fall., which cause considerable losses in the spring and summer respectively—cabbage pests generally are of considerable economic importance in this province. The staff of the Station appeared well informed on foreign practice; they were, for example, familiar with the proprietary organic mercury compounds used in Great Britain against smut (*Ustilago* spp.) on cereals.

The field station is chiefly concerned with the mass breeding of the Chalcid parasite *Trichogramma evanescens* Westw. for the control of a number of pests, particularly the codling moth, *Cydia pomonella* L., in apple orchards, and also the pea tortricids, *C. nigricana* Steph. and *C. dorsana* F. The parasites are reared on *Sitotroga cerealella* Oliv.; the stock culture of the latter is maintained in some three tons of grain.

The parasite was originally introduced from abroad, and the mass breeding work has been in progress for the last three years. A number of the collective farms in the province now breed their own *Trichogramma* for release; a peasant came in with a consignment of parasitized eggs from his collective farm for cold-storage at the Peterhof laboratory during the visit there. 2,500 acres of orchards have recently been treated, the parasites being released at the rate of about 120,000 per acre. Complete control is not claimed, but experimental results showing, for example, a reduction in the proportion of infested fruit from 33 per cent in the control areas to 17 per cent in the treated ones were quoted. The results suggest a localization of the activity of the released parasites which does not agree with the rapid dispersion found, for example, with *T. lutea* Gir. in the Transvaal, though environmental differences, mainly perhaps in temperature, may be involved here.

In conclusion, one or two general points concerning accommodation and equipment may not be out of place. Though most of the existing accommodation is of a temporary nature—the Institute of Plant Protection is to follow the majority of the central scientific institutions to Moscow within the next few years—one's general impression was not unfavourable. Equipment was surprisingly good; microscopes, micro-balances, incubators, electric motors and relays, constant temperature rooms, calculating machines, and glassware of all kinds may be mentioned as examples of Soviet-made apparatus apparently fully up to the standard of that in use elsewhere.

Noise and Housing

THE great interest which is being displayed at the present time in quiet housing is reflected in two reports which have reached us: the first, on the "Hygiene of Housing", from an international commission of the Health Organisation of the League of Nations; the other, on the "Construction of Flats for the Working Classes" (H.M. Stationery Office. 1*s*. net), from a Departmental Committee of the Ministry of Health. Both reports deal with various scientific and other aspects of the housing question, and are in general harmony as to the steps which should be taken in relation to the environmental problem of noise and its bearing on the amenities of housing.

The League of Nations Commission, under the chairmanship of Dr. G. W. C. Kaye, collated the experiences of a number of countries in lessening the nuisance of noise in many circumstances. The report directs attention to the significance of town planning by public or private authorities, with the view of locating dwellings in quiet areas, and securing the co-operation of industrialists in the lay-out of noisy plant. Not only external planning but also the interior planning of dwellings must be given close attention, so that, for example, bedrooms are allocated to the quietest rooms. Then again, dwellings may be insulated against external or internal noise or vibration by sound-proof walls, double windows, composite floors, suspended ceilings, resilient floor coverings, and sound-absorbent surfacings for walls and ceilings. Above all, noises should be reduced or isolated at the source; some countries have resorted to legal enactments and restrictions, but as regards others, research, education and the force of public opinion are more likely to be helpful. Among aggressively disturbing interior noises, particularly for flat dwellers, are powerful loud-speakers, hissing water taps and noisy sanitary fittings. Quieter motor-vehicles would be a boon for those who live and try to sleep in dwellings situated in busy thoroughfares. The report quotes standards of noise-level which are considered desirable and practicable in different classes of rooms in various locations, together with standards of noise opacity of walls and floors for air-borne and impact noises respectively.

The report of the Ministry of Health Committee, under the chairmanship of Sir George Humphreys, is on much the same general lines in its references to questions of acoustics. There is an appendix dealing with noise in working-class flats, which was prepared for the information of the Committee by the National Physical Laboratory and the Building Research Station. The Committee is impressed with the value of composite structures in arresting sound transmission, though it appreciates that the basic principles involved are not yet fully established. The Committee awaits the expeditious prosecution of research into the effects of specific forms of discontinuity in structural systems, and the provision of acoustic data for the different units of construction, not omitting, of course, the all-important matter of comparative cost.

Association between Nematodes and Insects

MR. PROSPER BOVIEN contributes an important paper (written in English) on the above subject, in the *Videns Kabelige Ueddelelseer fra Dansk naturhistorisk Forening*, 101, 1937, which has only recently come to hand. His investigations relate to the family Anguillulidæ, which may become associated with insects in various ways. From a survey of the literature, and his own investigations, the author concludes that these nematodes and insects may be associated in four different ways. (1) Symbiotic association, such species living in the frass or tunnels of wood-inhabiting beetles. Other species live in the nests of ants or termites. The prevalence of a special larval stage ("Dauerlarve" of Fuchs) has been ascertained in some instances. These larvæ may be carried externally, for example, under the elytra of beetles, loosely adhering or protected by a 'cocoon'. In some cases they may invade the gut, pharyngeal glands or the hæmocœl of the host. (2) Species found in dung and decaying vegetation which may pass through larval stages carried by insects loosely attached to the exoskeleton or firmly adhering as 'cysts'. Others have endoparasitic larvæ affecting insects. (3) There are also species which occur as actual parasites in the body-cavity of insects where reproduction takes place. (4) Species which combine parasitic and saprozoic types of behaviour.

Among the life-cycles studied by this author, special mention may be made of that of *Heterotylenchus aberrans* gen. et sp. nov. which is parasitic in the onion fly (*Hylemyia antiqua*) and of two new species of *Neoaplectana* which are abundantly present in larvæ of Bibionid flies. It is believed that the number of species with "Dauerlarven" is much larger than has been supposed. Their extraordinary power of resistance is commented upon and mention is made of finding living larvæ of *Aphelenchoides* in chrysanthemum leaves which had been kept for five years in a drawer in a laboratory. Among flies of the family Psychodidæ, up to 50 per cent were found to carry "Dauerlarven" of *Rhabditis dubia* sp.n. which are lodged externally like tightly fitting rings in the intersegmental furrows of the abdomen. When placed in dung, which harbours a rich population of Psychodidæ, these larvæ developed into adults in a few days. The paper is one of more than ordinary interest, commended to the notice of zoologists as well as to the specialist.

Science News a Century Ago

Arrival of the *Sirius* and *Great Western*

On the morning and afternoon respectively of April 23, 1838, the S.S. *Sirius* and the S.S. *Great Western* anchored in New York Harbour. The former had made the passage from Cork in nineteen days and the latter the passage from King Road, in the Severn, in fifteen days. Their arrival was the occasion for a remarkable outburst of enthusiasm. On April 23, 1838, the *New York Herald*, under the heading "The Beginning of the New Age in Steam Power", said, "The feelings of this community, on this occasion . . . can't be described", and the same paper the next day said, "The excitement yesterday was tremendous; from an early hour in the morning until dark, myriads of persons crowded the Battery to have a glimpse of the first steam vessel which had crossed the Atlantic from the British Isles, and arrived at this port. . . . This excitement was further increased by the arrival of the *Great Western*, from Bristol . . . making the passage in fifteen days, thus solving the problem of possibility, and showing what can be done by enterprize, expenditure, courage and skill, in encountering the stormy weather which these two vessels have so successively braved and surmounted."

To Lieut. Roberts, the captain of the *Sirius*, the British Consul wrote on April 23, "I have the honour and happiness to congratulate you on the arrival of your steamship across the Atlantic, at a season when strong gales so generally prevail, thereby having proved that British skill had accomplished a most important enterprise, which will produce a revolution in commercial and social intercourse, of which we are incapable of forming any just conceptions. Permit me, Sir, to add that I have, in common with my fellow subjects of Her Majesty in this City, a further cause of rejoicing, that the honour of accomplishing the enterprise has been achieved by a son of the British Navy, and that it was completed on St. George's Day."

Line of Levels across Northern Syria

At a meeting of the Royal Society on April 26, 1838, a paper was read entitled, "An Account of a Line of Levels, carried across Northern Syria, from the Mediterranean to the River Euphrates", by W. T. Thomson, with geological and botanical notes by W. Ainsworth. The line of levels was undertaken in connexion with Colonel Chesney's expedition of 1835 sent out to determine the possibility of placing steam boats on the Euphrates and Tigris and so connecting with India by steam. One of the results of the expedition was to show that the bed of the Euphrates was 628 ft. above the level of the Mediterranean. The whole of the district over which the line of levels was carried, said Thomson, naturally divides itself into four regions, each of which is characterized by its relative elevation, and the manners and habits of its population. The first region commencing from the Euphrates comprises the country of the upper chalk and conide limestones, which averages an elevation of 1300 ft. The soil is light, somewhat stony, and of no great depth, and is highly productive in crops of corn and cotton. The second region comprises the country of ostracite limestone and feldspath pyroxenic rocks, having a mean elevation of 450 ft.; the third is the lacustrine plain of Umk about 305 ft. above the Mediterranean and covered for the most part with the gramineous plants which feed the flocks of the pastoral and nomadic Turcomans; and the fourth region, formed by the valley of Antioch, is rocky and irregular with elevations from 220 to 440 ft. It comprises also the alluvial plains of the Orontes.

Smallpox among American Tribes

The issue of the *Gazette des Hôpitaux* of April 26, 1838, gives the following account of a severe epidemic of smallpox which was prevalent at that time among some American tribes: "The situation in Upper Missouri is appalling. Small-pox, or the 'black disease', as it is called, has chiefly attacked the tribe of the Assinaboins. After death caused by the disease the body becomes quite black and swollen to thrice its ordinary size. People are actively engaged in collecting the bodies and burning them in heaps. The Sioux tribe which has been vaccinated has hitherto escaped infection. Nearly all the tribe of the Mandans, numbering 1,600 souls, who lived above Saint Louis, have disappeared, only 31 being left. The pestilence has attacked the Minaterees or Big Bellies, another neighbouring tribe, with equal violence. The Arickareas as well as the Grees have been almost entirely destroyed. The Assinaboins with a population of 9,000 no longer exist. The great nation named Black Feet numbering 50,000 or 60,000 inhabitants has suffered severely. More than a thousand houses each containing eight inmates have been decimated. It is probable that all the tribes in the Columbia region as well as those extending to the south of Missouri will be affected."

The *Athenæum* and Postal Reform

The *Athenæum* devoted the leading articles in its issues of April 21 and April 28, 1938, to a review of the "Minutes of Evidence taken before the Select Committee on Postage", printed by order of the House of Commons. The Committee had been appointed largely through the proposed reforms set out by Rowland Hill. Much evidence had been given of the various means used by individuals and business houses to evade the very high rates of postage charged by the Post Office, and in commenting on this the *Athenæum* said, "We might almost say that *fortunately* for trade and commerce, the operation of the government monopoly is counteracted by the clandestine conveyance of letters. The means of evasion are so obvious and frequent, that the post has become only the extraordinary, instead of the usual channel for the transmission of business letters." The postage was then for all intents and purposes little more than a tax and a source of revenue and not a means of promoting trade.

In connexion with the proposal that prepaid envelopes should be provided, it had been suggested that this would lead to forgery. To counteract this, it was proposed that a peculiar paper with lines of thread or silk stretched through its substance should be used. The advantages of such paper were that it would be difficult to make and counterfeit, and by diversifying the colour, material and arrangement of the threads, forgers could be defeated. To illustrate the use of this device, the *Athenæum* instructed Mr. Dickinson, the inventor, to supply paper of this kind for its issue of April 28, which accordingly appeared with some of its sheets made of paper containing fine blue threads half an inch apart.

Societies and Academies

Dublin

Royal Dublin Society, February 22.

Phyllis Clinch, J. B. Loughnane and P. A. Murphy: A study of the infiltration of viruses into seed potato stocks in the field. The infiltration of viruses into seed potato stocks in the north-west of Ireland was studied. The only viruses found were *X*, *B* and *A*. It was found possible to grow stocks for six years without incurring any virus infection.

J. B. Loughnane and P. A. Murphy: Dissemination of potato viruses *X* and *F* by leaf contact. Virus *X* (*Solanum virus* 1) spread freely to potatoes under controlled experimental conditions both under glass and in the field by leaf contact, virus *F* (*Solanum virus* 8) was found to spread similarly under glass, and there is evidence that virus *B* (*Solanum virus* 4) can be conveyed in the same way. Some potato viruses are transmitted by leaf contact as well as by insects.

E. J. Sheehy and W. Kearney: The occurrence of the uræmic condition in chickens, and its relation to protein and other dietary factors. Evidence is presented to show that this disorder is connected with both the protein and the non-protein constituents of the dietary, and that it is controllable.

G. T. Pyne and L. Ó. Droma: The rôle of albumin in cheese-making. Experiments on the preparation of Cheddar cheese from pasteurized milk to which albumin had been added both before and after pasteurization show that the detrimental effect of pasteurization on cheese-making (in so far as it acts through its effect on albumin) is due to precipitation of albumin on the casein micelles rather than to any change in the soluble albumin content of the milk.

Edinburgh

Royal Society, March 7.

W. T. Gordon: *Tetrastichia bupatides*, a carboniferous Pteridosperm from East Lothian. On the theory that magmatic waters emitted from volcanoes in eruption might decompose the ashes and thus produce petrifying solutions, a successful search for petrified plants was made at Tantallon Castle, East Lothian, in ashes of Lower Carboniferous age. One of these plants, *Tetrastichia bupatides*, possessed a stem with central xylem cylinder, cruciform in section, and, save for the spiral protoxylem elements, composed entirely of reticulately thickened tracheids. The petiole at certain levels had a trace similar to that described in *Lyginorachis papilio*, and the sclerotic elements resemble those found in *Telangium affine*. The new plant has the simplest structure of any known Pteridosperm.

N. W. Radforth: An analysis and comparison of the structural features of *Dactylotheca plumosa* Artis and *Senftenbergia ophiodermatica* Göppert. Of these two Carboniferous fern-like compressions, the former has been regarded as a true fern with annulate sporangia, while the latter was believed to be a Pteridosperm from the nature of its apparently exannulate sporangia. However, this analysis has shown that the fructifications of *Dactylotheca plumosa* are definitely annulate and identical with those of *Senftenbergia*. Moreover, from a comparison of other structural features it is clear that these two fossils are merely different parts of the same plant, and therefore can no longer be regarded as belonging to separate genera. Since the name *Senftenbergia* has priority, this genus must now embrace the forms previously described as *Dactylotheca plumosa*. The spores, which hitherto had not been revealed, have been isolated from the sporangia in their various developmental stages. Both the sporangia, the structure of which has been worked out in detail, and the mature spores which are characteristically ornamented, resemble so closely the sporangia and spores of the living fern *Aneimia* that the view of a possible relationship between *Senftenbergia* and the living Schizaeaceous ferns to which *Aneimia* belongs, is now greatly strengthened.

A. C. Aitken: Studies in practical mathematics. (3) The application of quadratic extrapolation to the evaluation of derivatives and to inverse interpolation. The first part of the paper shows how to interpolate by quadratic proportional parts (quadratic extrapolation) for the value of a function and several of its derivatives at the same time. The second part of the paper shows how quadratic extrapolation may be made available for inverse interpolation. A set of crude approximations to the desired value of the variable, given by ordinary proportional parts, yields in general very accurate values when treated by quadratic extrapolation.

C. E. Fawsitt and R. W. Stanhope: Viscosities of some complex salts in aqueous solution. Solutions of complex salts containing copper, silver, zinc, nickel and cobalt along with ethylenediamine and pyridine were examined for viscosity. Most of these solutions have a greater viscosity than that of the corresponding simple salts. However, the viscosities of zinc and nickel salts with ethylenediamine are scarcely different from the viscosities of the simple salts. The ethylenediamine copper salts have a lower viscosity than the corresponding simple copper salts. The electrical conductivities of the complex zinc and copper salt solutions (dilute) containing ethylenediamine are slightly greater than those of the simple salt solutions.

A. J. Birch: (1) Exudation of *Araucaria Bidwilli*. The exudation is shown to consist of a gum oleo-resin, the former containing pentosans, and the latter d-limonene and unidentified esters. (2) The α-phellandrene fraction of eucalyptus oils. An extension of the method already described by Birch for the detection and estimation of α-phellandrene is given, which enables the detection of dl α-phellandrene in the presence of active substance. The method is applied to the examination of the α-phellandrene fractions of the oils of ***Eucalyptus dives*, *E. Risdoni*, *E. Radiata*** and ***E. Amygdalina***, the first three of these oils containing large amounts of p-cymene, and the last dipentene. In no case is dl α-phellandrene present. A commercial sample of α-phellandrene contains p-cymene and origanene. It is suggested that the presence of p-cymene in α-phellandrene largely accounts for the variations observed in the optical rotation.

Germaine A. Joplin and Alma G. Culey: Geological structure and stratigraphy of the Molong-Manildra District. Silurian, Devonian, Tertiary and Recent formations have been recognized, and a detailed description is given of the Palæozoic strata. The Silurian has been divided into an upper (Manildra) and lower (Molong) series. Middle Devonian (Garra Beds) and Upper Devonian (Lambie Beds) are both recognized and all the Palæozoic rocks have been shown to be conformable. It has been pointed out that folding took place during the Kanimbla Epoch at the close of the Devonian, and that the Palæozoic series have been thrown into folds trending a little to the west of north.

Science and Society

AT last there are signs, in Great Britain at least, of a rapidly growing awareness of the importance of those complex problems confronting our community, due primarily to the astonishing rate of advance of scientific knowledge during the last generation, a rate which is accelerating even as we study it. Our social outlook and our social institutions toil feebly behind this advance and, lagging as they do, permit the placing of weapons of unparalleled potency for good or evil in the hands of those who may, alas, be unfit to use them. Faced with an annihilation of distance which makes it possible to put a girdle round the earth in a few days, to discuss, as an everyday matter, the possibility of establishing aeroplane factories in Canada for the supply of Britain; with methods of transport which, thanks to the labours of physicist, engineer and biologist, bring the fruits of the earth in perfect condition from the antipodes to our shores—give us, in Sir William Hardy's words, "Summer all the year round"; with the knowledge that "the growth and health of children in poor industrial areas and in the homes of many agricultural labourers are still seriously handicapped by protein and vitamin deficiencies", and that "the evidence for this has been fully substantiated by social and dietary surveys"; men of science must obviously accept a certain amount of responsibility for the solution of problems created by them.

These problems, raised by increase of knowledge, are met by social and economic—what for the use of a better word must be called 'plannings'—which might have been adequate to the needs of an era when a sparsely populated nation could be considered roughly as a self-supporting economic unit; when national patriotism, itself a plant of comparatively recent growth, was well enough fitted to the age in which it flourished; when a great man of letters could write of that bloody swathe which the dæmonic energy of Napoleon was cutting across Europe—"this war, of which philosophers take no heed"; but they are not adequate to-day, when the whole structure of civilized life is in peril. Here are problems of plenty and of deficiency, of war and of peace, which, in the terms of their presentment, are peculiarly the products of our own age—most of them problems which the world has never before been forced to meet. What contribution can the man of science make towards their solution?

It is a moot point whether he, as a social and political animal, has been greatly influenced by his own scientific outlook. Faraday shut the door of his laboratory when he went into his oratory, and the man of science too often in the past has kept his political and scientific methods completely separate, and has been as much a victim to prejudice as his brother trained in the humanities. It is this tendency to arrive at political and ethical conclusions in terms of emotional reactions rather than rational judgments which makes government an art—the cynic would say, a dodge—rather than a science; which gives point to the demand for a "World Encyclopædia", recently stressed by Mr. H. G. Wells. It is a hopeful sign that, as was shown in the columns of the last issue of NATURE, so great a mass of considered opinion is so fully awake to the fact that it is worse than useless to meet these problems of our own age, armed with machinery devised to deal with those of the eighteenth and nineteenth centuries.

The correspondence shows a remarkable consensus of opinion. Practically all are agreed that some organized body is necessary which shall study the problems, many of them highly controversial, evoked by the impact of science on society, in an objective and rational manner. Such a body must have the closest linkings with the physical and biological sciences, with economics, engineering, psychology, anthropology and sociology. It must provide a platform for free and frank debate ; it should conduct its investigations as much by means of research committees and discussions as by the formal reading of papers ; it should endeavour to make its findings plain to the man in the street.

There can be no question as to the need for such work to be undertaken. The present age is deafened by the cries of advertisers of nostrums of all kinds ; and those of us who believe that, before all and above all, reason, and conviction by an appeal to reason, are the indispensable bases for any ordered, successful and permanent social advance, cannot but be alarmed at the growing tendency to explosions of mass-hysteria. It is only when reason provides the outlook that the emotions may be trusted to control the direction. In a society such as is proposed it is of the first importance that its explorations should be conducted and its conclusions reached in a detached and cool spirit. Coolness does not mean cold-bloodedness nor does it connote any hesitation in pursuing the right path once that path is known.

The main problem being one of the interaction of science and social relations, it is clear that, as Prof. Ginsberg has put it, "the study of the effects of science on social relations requires not only a knowledge of science, but also of social relations". The problems are, in fact, sociological, and the society which undertakes the task of studying these repercussions must have a very wide field on which to draw. It may be that the ends in view will best be served by the formation of a new society charged with the special task of surveying and interpreting the social relations of science, but before actually constituting such a society, the British Association, itself a pioneer in the attack on some parts of the problem, might be invited to undertake the task.

As some correspondents have pointed out, the annual meeting of the Association provides an admirable platform from which to announce progress, but that much more than this is needed : and much more is possible. Already the Association is enlarging its activities to meet the changing needs of a changing era. It has initiated, in many of its sections, papers and discussions which touch upon these topics ; it has taken part in the jubilee meeting of the Indian Science Congress Association, recently held in Calcutta, thereby establishing an important principle of overseas delegations. At the present moment its general officers are in consultation with their colleagues of the American Association for the Advancement of Science on a scheme for international co-operation such as that Association has recently adumbrated. The Association possesses sections the work of which touches closely that of a society for the study of social relations, and it is second to none in its experience of the manner of work of research committees. Is it too much to suggest that the Association might very well consider the arranging of discussions of these problems to be held in London or elsewhere at regular intervals outside the annual meeting ? For the organization of such meetings, and the undertaking of appropriate investigations by research committees, an entirely new department of the Association might be constituted. It seems to us that this plan would be preferable to the addition of a new section, or sub-section, to deal with the social relations of science.

A new society of the kind contemplated implies much more than an annual report ; and if the British Association accepted responsibility for its functions, either by the formation of a new department or otherwise, the present annual report would have to be supplemented by a new periodical publication comparable to the proceedings or journals of other societies, and devoted mainly to the advancement of knowledge of the impact of science on society and of society on science.

It may be that the serious questions of finance and of policy involved will make it too difficult for the Association to undertake this work. But in its constitution and outlook it is at least a possible body to undertake such duties, and its long and brilliant traditions are sufficient guarantee that the work, if undertaken, will be carried out in the true spirit of science and of public service. We suggest, therefore, that when a meeting is held to discuss proposals for constituting a body to organize inquiries into the social relations of science and publish the results, the possibility that the Association might accept this responsibility should be considered. Even if the Association fails to do so, for financial or other reasons, it might in many ways assist the work of any new society which may be formed.

The Mandæans

The Mandæans of Iraq and Iran:
Their Cults, Customs, Magic, Legends and Folklore. By E. S. Drower ('E. S. Stevens'). Pp. xxvi + 436 + 29 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 25*s.* net.

HITHERTO our knowledge of the Mandæans—a small community of some 5,000 souls dispersed over a few places in Iraq and Iran—has been confined to the writings of Lidzbarski and Brandt, which rested on such scanty texts as had found their way to Europe, and the casual observations of Petermann, who spent three months in 1860 in the marshes of Lower Iraq, and of various other travellers whose curiosity they aroused. The results of these labours were not altogether satisfactory: Petermann's sojourn was too short to give him more than a modest acquaintance with a single community, while the works of Brandt and Lidzbarski suffer from a lack of any knowledge of the people themselves. Mrs. Drower, whose husband held a position as judicial adviser in Iraq, has the double advantage of having been able to familiarize herself with the remains of Mandæan literature and of having been resident in Bagdad since 1922, with ample opportunities of investigating the customs of these interesting people at first hand.

At the beginning of this period, Mrs. Drower was compelled to carry out her work through the medium of Arabic, but since 1931 she set herself to learn also Mandaic, the ancient Aramaic dialect in which the sacred books of the Mandæans are written and their rites carried out, but which is now rapidly dying out in ordinary use; and almost the only regret which the reviewer has is that she is not a trained philologist, as she herself confesses and as some of her transliterations and translations show, since the dialect is linguistically of some interest and Nöldeke's "Mandäische Grammatik" deals only with the language as known in a few published texts.

The Mandæan religion, which is generally regarded as a kind of Jewish gnosticism from the Aramaic *manda*ᶜ 'knowledge' (though Mrs. Drower doubts this explanation), whence its name is derived, is based on the ancient worship of the principles of life and fertility, and the symbol of the 'Great Life' is running water—a natural idea in a country which the two great swiftly flowing rivers, the Tigris and the Euphrates, traverse—and it follows from this that the central rite is baptism or rather total immersion in flowing water. The second great life-giving power is light, bestowing health and strength, virtue and justice. The third important element is the doctrine of the immortality of the soul and its close connexion with the souls of its ancestors. From this insistence on 'living', that is running, water is derived one of the two reasons why the Mandæans have such contempt for Christians, inasmuch as these use 'dead' water for their baptisms. The other is the celibacy of their monks and nuns, since the Mandæans regard the procreation of children as a religious duty; indeed, they go so far as to hold that even the most pious Mandæan, if he dies childless, after passing through a state of purgatory and a sojourn in the worlds of light, must return again to a physical state and become a father.

Mrs. Drower offers various conjectures about the origin of the Mandæans and, what is of great interest, tells much of their own traditions. Thus they claim descent from the ancient Egyptians and annually partake of a ritual meal in memory of those Egyptians who perished pursuing the "wicked Jews" across the waters of the Red Sea, while she shows that their doctrine has clear affinities with Mazdæism. A very primitive water-cult seems in fact to lie behind Mandæism, but very diverse elements have been absorbed into it, especially from Babylonian religion and that of the Parsis: for example, the ritual immersion of the priests is probably of Babylonian origin and writing and books are under the charge of the planet *Nbû*, who is none other than the Biblical Nebo (Isaiah xlvi, 1) or Babylonian *Nabû*, the patron deity of scribes, while the ritual meals (apart from certain specific differences) closely resemble those of Indian Parsis. Even the baptism of Adam has become the occasion of an annual feast!

Some Mandæan practices strike the modern reader as strange, if not actually revolting. Thus an expectant mother is removed for her confinement from the house, which she may pollute, to a cattle-shed or store-shed, where she spreads "something soft or without value, such as old clouts" in a corner on the ground and is there delivered; the mother is then immediately, if possible within half an hour, helped down to the river by the midwife and subjected to three complete immersions with the customary prayers; but, if the weather is cold, she may be soused in the place where she is lying. In view of these and the other baptisms and rites which mother and child undergo, it is scarcely surprising that the Mandæans are not a growing community. The dwindling is helped by the spread of education, which is driving the young people into the towns where, even if they wished it, there are not always adequate facilities for continual baptisms in running water; for the oftener a man is baptized (for example, after marriage, birth, illness, travelling, touching the dead, every conceivable sin, and so on) the better, since "baptism, alms, and good deeds make the perfect Mandæan", and these good deeds include scrupulous performance of death-rites and observance of the cult of the dead. What this may mean may be gathered from the fact that the author herself was present at a single ceremony which lasted eighteen hours! Further, the true Mandæan generally refuses to take any medicine even after going to a European doctor, although he has faith in ointments and does not object to injections; and during a recent cholera outbreak one community refused to drink boiled or chlorinated water on the ground that it was 'dead'.

At the same time the priesthood, which is for the most part hereditary, is being recruited with increasing difficulty, partly because of the high standard of pure Mandæan blood and of freedom from physical blemishes required in the priest, and partly because of the growing difficulty in modern cities of finding an unpolluted foreshore where he may carry out his innumerable baptisms in running water. Further, consecration to the priesthood is no light affair: it can take place only when some pious and aged person of ritually pure and priestly stock is at the point of death, and the consecrated priest can carry out no office until he has performed the ceremony of marriage for another priest; if no priest is willing to get married, the new priest remains isolated until one is found ready and willing to contract a marriage (which is not difficult in a polygamous community) to oblige his colleague. It is, too, a symptom of decay that there has not been 'a head of the people', that is a 'chief priest', who attains that rank automatically on having consecrated five priests, for the last eighty years.

Mrs. Drower has divided her book into two parts, the first containing an account of the life and religion, customs and ceremonies of the people, and the second giving a number of folk-tales which she has taken down from the lips of her informers. The book is an admirable example of the results of field-work undertaken by a competent observer and checked by an adequate control of the literature of the subject; and even though a reader may and indeed will disagree with some of the author's suggestions in the sphere of comparative religion, he can only be grateful that she has gathered such a wealth of information at a moment when the Mandæan religion seems likely to disappear before the inevitable advance of modern civilization. The book will henceforth be indispensable as a corrective to the works of scholars who have written on the same subject without ever having set foot outside Europe.

G. R. Driver.

Science at Large

Obsessions and Convictions of the Human Intellect

By F. W. Westaway. Pp. xvi + 528 + 4 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1938.) 10*s*. 6*d*. net.

The plan of Mr. Westaway's book is ambitious. It is difficult to give adequate treatment to so large a number of subjects within the compass of a single volume, even of 500 pages. It is not merely that the topics are so numerous; they are so diverse. Thus Mr. Westaway not only introduces us to what may be termed pre-science, like astrology and alchemy, but also to modern forms of pseudo-science, such as palmistry, phrenology and so on. He deals, too, with witchcraft (showing that one may be thankful for some changes that science has wrought in human mentality), with squaring the circle and the history of π, with perpetual motion devices, as well as with theories of a fourth dimension. There follows a chapter on space and time and the idea of infinity, and one on scientific method. We are then conducted through the biological sciences, and afterwards into the realms of metaphysics and theology.

The volume is certainly one to be placed in a school library, and should help to give young science students (and even their teachers) the synoptic view which is in danger of being destroyed by too much specialization. The preface shows that Mr. Westaway is interested in the mental outlook of sixth forms, and perhaps the intelligent senior schoolboy would be the kind of individual to profit most from this book, which incidentally is not superficial though it is popular. Each chapter has a good bibliography. Perhaps the chapters on the physical sciences are the best i the book, but the early chapters, being so full unusual material, are highly interesting. When the author approaches the biological sciences, he writes with a refreshing absence of dogmatism. "We certainly still are profoundly ignorant of the real nature of either life, consciousness, or personality."

In approaching metaphysics, Mr. Westaway treats the subject without condescension, as being worthy of serious study. It is certainly good for science students to realize what difficult problems arise out of their own most familiar experiences, as well as out of the methods which they employ in their researches. The theological chapters attempt to make available some of the results of recent historical inquiry, as well as of the critical study of the New Testament. Though the scope of the book is already so wide, one could wish that a discussion of art as well as of religion had been included. Some acquaintance with the philosophy of art is calculated to widen the outlook of the scientific specialist even more, perhaps, than the study of religion (and the practice of art is no less valuable than the practice of religion). In art there are few vested interests in dogma such as those which are apt to deflect the scientific worker's interest from religion. But Mr. Westaway has been so generous that to ask for more seems out of place.

J. C. H.

Geographical and Economic Survey of Great Britain

The British Isles:
a Geographic and Economic Survey. By Dr. L. Dudley Stamp and Stanley H. Beaver. With Contributions by Sir Josiah Stamp and Dr. D. K. Smee. Second edition, revised throughout. Pp. xii + 719. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1937.) 25*s*. net.

In his preface to "Britain and the British Seas" Mr. (now Sir Halford) Mackinder wrote: "Britain is . . . known in such detail that it has been possible to attempt a complete geographical synthesis." In the thirty-five years that have passed since that work was published nothing has appeared to take its place. At the same time much work has been done on these Islands and one has only to glance at the references at the end of the chapters in the present volume to see to what extent Dr. Stamp and Mr. Beaver have been able to draw on the achievements of their fellow geographers spread over a period which has seen both the consolidation of geographical research in Britain and the vindication of the principles propounded in "Britain and the British Seas".

Between the appearance of this latter work and that under review, three books of importance to geographers have been published. The first volume of "The Oxford Survey of the British Empire" (1914) is most closely comparable to the present work in that it consists of a series of studies of aspects of the British Isles by acknowledged experts. M. Demangeon's "Les Iles Britannique" (1927) is an excellent representative of the French 'school' of regional geography, while the volume of "Essays" edited by Prof. A. G. Ogilvie (1928) treats in detail but with varied emphasis regions in Great Britain the boundaries of which were somewhat arbitrarily determined. The present work deals with these Islands in greater detail than any of the others, and the fact that a second edition has been called for within four years of its original publication is a tribute to its usefulness. It has become a standard text-book the general accuracy of which is vouched for by the co-operation of no fewer than nineteen "experts in many of the various fields covered". For this reason, if for no other, it will probably long maintain its place as a valuable work of reference.

Yet herein lies its weakness. What is wanted is a new 'geographical synthesis'. Dr. Stamp admits to, and this book reveals, a passion for facts. Facts are necessary, but facts alone cannot make geography: without vision, geographers must perish. This lack of vision is shown both in the general arrangement of the book and in the unevenness of its various chapters, some of which are long and valuable essays embodying much research while others are mere paraphrases, sometimes scarcely adequate, of the work of others. When the next edition is called for, is it too much to ask that the authors will indicate by way of summary or synthesis what is the hope that is in them—they quote from "Cavalcade"—and wherein is to be found the "dignity and greatness and peace" of Britain? Is it to be found in the use of the land or of "National Capital"? Or rather, is it not to be found in the part which the resources, and their use, will enable the British people to play in world affairs?

To come to narrower limits, it would be of advantage to think out the modern counterpart of Sir Halford Mackinder's 'metropolitan' and 'industrial' England. In this book, one is confronted with thirteen 'industrial regions' in Britain; twenty-five 'agricultural regions', with many sub-divisions, based to some extent on the

'Highland' and 'Lowland' zones; a different set of nineteen 'physiographic and structural units' based on the same zones; and a suggestion in Fig. 234 that, from the point of view of population density there are three divisions which "correspond roughly with industrial, good agricultural, and poor agricultural tracts". With all these ingredients could there not be a consideration of geographical regions? Or is geography to concern itself only with the distribution of different facts? Now that the authors have drawn upon the specialists, one is confident that they could undertake this formidable task. If they do they could then call the next edition of this book "The Geography of the British Isles".

J. N. L. B.

Progress in Enzyme Chemistry

Ergebnisse der Enzymforschung
Herausgegeben von F. F. Nord und R. Weidenhagen. Band 7. Pp. xiv + 437. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1938.) 34 gold marks.

This year's volume follows the now well-known lines: it is substantially larger, perhaps indicating the intense interest in the subject. With one exception, the articles are in English or German; that on sulfatases by Cl. Fromageot is in French. As usual they cover selected sections of experimental activity which can conveniently be summarized at this moment.

Pride of place may be claimed for M. L. Anson's brief note on crystalline carboxypeptidase, a long name for a pancreatic enzyme which, however, is explicit as to the action it performs. The enzymes are now largely regarded as proteins, so that it is a question of finding out the right conditions for their isolation, when the further investigation of their structure can go hand in hand with that of the proteins. Interposing, the view may be expressed that this particular problem of protein structure is not being attacked with all the forces that its importance indicates. Anson stresses the extreme difference in the protein properties of the various enzyme proteins, which have so far contributed to prevent their isolation by standardized systematic procedures. It is clear now that ordinary cells contain a multiplicity of proteins and that the specific properties of these serve to control many of the chemical reactions which take place in living cells. The control exercised by varying the stereochemical configuration of such a relatively simple substance as glucose has been often stressed; obviously with the complex proteins the possibilities of variation are infinitely more numerous.

Next in significance may be placed the story by H. Raistrick of some aspects of the biochemistry of the lower fungi, which indicate certain relationships in structure between the large number of mould metabolic products. The interesting conclusion is expressed that one of the first stages in the life of most fungi is that of synthesis of a complex polysaccharide from the nutrient available in the same way that starch is a primary product of synthesis in the green plant. At a later stage this polysaccharide is broken down in a variety of ways, giving rise to the characteristic products of the individual race. Renewed interest is at once attached to such polysaccharides and to their structure—four new ones are described.

The question of the relation of specificity to chemical structure continues to promote investigation. It is the basis of a well-compiled report on immunochemistry and its relation to enzymes by J. Marrack, as well as the article on emulsin by B. Helferich, who has long been the protagonist for ascribing a wide range of activity to this enzyme rather than regarding it as a mixture. His arguments are not altogether convincing. A new point of importance here is the hint that the tryptophane unit in emulsin has a role in its activity.

The knowledge of the group of ferments which breaks down the nucleic acids has progressed to a satisfactory stage and it is valuable to have a crisp summary of these nucleases compiled by H. Bredereck.

Among the more difficult articles is one from the pen of Otto Warburg on the chemical constitution of the enzymes, a question to which an answer is anxiously awaited. The treatment is largely mathematical and concerns the relation between the metallic prosthetic group and the conjugated protein for certain oxidizing and reducing enzymes.

The technical article this year concerns the part played by enzymes in the tanning industry; it is written by F. Schneider and covers a wide field in forty pages. Of technical interest also is a summary of the biochemistry of acetic acid bacteria which indicates all the more recent observations.

The examples selected suffice to show the wide range of subjects covered and the utility of the "Ergebnisse" in these days when it has become impossible to keep up with the original literature.

E. F. A.

Leçons d'algèbre et de géométrie à l'usage des étudiants des Facultés des Sciences

Par Prof. René Garnier. (Cours de la Faculté des Sciences de Paris.) D'après la rédaction de Badrig Guèndjian. Tome 3 : Élimination, éléments de géométrie réglée, transformation de Lie, applications à la géométrie conforme. Pp. vi+280. (Paris : Gauthier-Villars, 1937.) 80 francs.

THIS is the third volume of a series of "Leçons d'algèbre et de géométrie" written by Prof. Garnier for the use of students in the Faculty of Science at Paris.

The subject-matter in the present volume should appeal to the analyst who desires to study some higher geometry by his own favourite methods. The course starts with a chapter on algebraic equations, and consists of two main sections devoted respectively to symmetric functions and elimination. This provides a foundation for the remaining part, which deals, in seven chapters, with higher geometrical conceptions treated algebraically. The notion of a locus is first carefully developed and extended to conoidal surfaces as well as to those of revolution. Then follow chapters on Plücker's line co-ordinates, the linear complex, the tetrahedral complex, Lie's transformation, in which is included a discussion of pentaspherical co-ordinates, and an application of the transformation to curvature. Parts of the text are amplified in four short notes and additions given at the end.

The text is clearly written with great care and precision, and is quite easy to follow in spite of the fact that the subject-matter is by no means of an elementary character. There are, as usual in many French mathematical text-books, no exercises, but the whole course is both interesting and stimulating.

Das Sammeln, Konservieren und Aufstellen von Wirbeltieren:

Leitfaden für Sammler, Liebhaber und Fachleute nach neuzeitlichen Gesichtspunkten. Von Gerhard Schröder. Pp. viii+93+32 plates. (Berlin : Paul Parey, 1936.) 4.80 gold marks.

SO far as precept, in place of the experience of watching a taxidermist at work, can instil methods of preserving and mounting vertebrate animals, this little book by the taxidermist of the zoological museum in the University of Berlin is a useful guide for collectors and amateurs. It describes the methods of skinning birds and mammals, the mounting of birds' skins, and the making of models and plaster casts of the larger mammals in the modern method for use as the foundation of the final mount.

The progressive stages of these processes are well illustrated by photographic reproductions. Plaster and paraffin moulds are recommended for fishes and reptiles, but no mention is made of the celluloid coatings which have proved so life-like in the construction of reptilian models in some American museums. Hints are given regarding the construction of large habitat groups.

Descartes' Discourse on Method

By Prof. Leon Roth. Pp. viii+142. (Oxford : Clarendon Press ; London : Oxford University Press, 1937.) 6*s*. net.

THE year 1936 marked the tricentenary of Descartes' "Discourse on Method", so Prof. Roth's study is both timely and welcome. A turning point in European thought, the "Discourse" has a story of its own, which is carefully recounted : we are shown that if it is formally true to look upon it as the introduction to Descartes' philosophy, this short work is materially a retrospect, a summing-up of a life's achievement, rather than the laying down of a programme ; hence its primary importance for the understanding of Cartesian philosophy.

The method proposed by Descartes is typical of philosophical rationalism : the rule of 'division' and of the unilateral 'order' is its keynote. But the method itself proved to be inadequate to Descartes' purpose, which was to substitute a physics based on metaphysics for a metaphysics based on physics, and to treat physics as a part of mathematics. The linking of the "Method" with physics proved to be disastrous. Their dissociation, effected by Descartes' critics, saved his philosophy from a total eclipse. Thus, Cartesianism has survived, not as a system of physics or metaphysics, but as a general method of analysis.

In estimating the nature and fate of Cartesianism, Prof. Roth is thus led to discuss the whole problem of the value of the mathematical outlook and the general competence of the mathematical mind. His excellent study may be considered as a lucid introduction to the history and problems of modern thought.

T. G.

Introduction to Mathematical Probability

By Prof. J. V. Uspensky. Pp. ix+411. (New York and London : McGraw-Hill Book Co., Inc., 1937.) 30*s*.

PROF. USPENSKY'S treatise on mathematical probability is a very comprehensive one and includes every theoretical aspect of the subject, with several chapters on modern developments. Only those investigations in theory which touch the philosophical borderline and researches such as those of Reichenbach concerning possible connexions with the polyvalent logical systems, are not reviewed. Chapters i–xii of the work do not presuppose any advanced mathematical knowledge, while Chapters xiii–xvi present all the chief results of modern investigations. There are three appendixes to the book, in one of which an outline of the famous Tsebysheff-Markoff method of moments applied to the proof of the fundamental theorem previously established by another method in Chapter xiv is given.

Problems are appended to every chapter, and for an advanced student there could not be a more admirable text-book from the purely mathematical and theoretical point of view. For just as no philosophical discussions are included, neither does the book go into any of the applications of probability to other sciences.

The Pragmatic and the Dogmatic Spirit in Physics

By Prof. J. Stark, President of the Physikalisch-Technischen Reichanstalt, Berlin-Charlottenburg

THE aim of physical science is the investigation and formulation of the laws which govern the properties and processes observed with objects of inanimate Nature. These inherent laws are independent of human existence, action, and thought, and are the same all over the world. For this reason, the object of physical science is international. But the manner in which physical research is carried out and described depends on the spirit and character of the men of science engaged upon it, and this spirit and character differ individually, as do men, nations and races.

When in what follows I speak of two principal types of mentality in physics, my observations are founded on experience. I have inquired into the mental characteristics that have led the great physicists of the past to their discoveries, and in the course of the forty years of my scientific life I have observed very many more or less successful contemporary physicists and authors of theories and of books, in an endeavour to discern the mainspring of their work. On the basis of this wide experience I have come to recognize that there are two main types of mental attitude among workers in the field of physics.

The pragmatic spirit, from which have sprung the creations of successful discoverers both past and present, is directed towards reality; its aim is to ascertain the laws governing already known phenomena and to discover new phenomena and bodies as yet unknown. Even before they tackle a particular problem, physicists of this school of thought have acquired a certain feeling of the reality of the phenomena to be investigated, by giving careful attention to all previously ascertained facts connected with their problem. On the basis of this feeling they form a conception as to what the body or process to be investigated may be like in reality. For them, however, such a conception is solely the means to the end of devising experimental arrangements for the empirical formulation of their question to reality itself. If the observations made with the apparatus chosen do not confirm the initial conception, as very frequently happens, they reject it without hesitation and seek stimulation from experience for a new conception for the purpose of new experiments. Their final goal is always to establish reality, whether they gain new knowledge or are led to obscure and still unexplored features of the phenomena investigated. The mathematically formulated theory is to physicists of the pragmatic spirit not an end in itself, but solely a method for the purpose either of presenting the knowledge gained from experience in a quantitative manner and as briefly and simply as possible, or of deriving mathematically for special cases results which follow from general laws obtained from experiment.

The physicist of the dogmatic school operates in quite a different manner in the field of physics. He starts out from ideas that have arisen primarily in his own brain, or from arbitrary definitions of relationships between symbols to which a general and so also a physical significance can be ascribed. By logical and mathematical operations he combines them and so derives results in the form of mathematical formulæ. He then seeks to give these a physical meaning by applying them to the results of experience. In so far as they are found to be in accord with experience, he underlines this agreement with the greatest of emphasis, and makes it appear as though the results of experience have been established and have gained scientific importance only by virtue of his theory. If there are any experimental results available that are not embraced by this theory or which stand in contradiction to it, he doubts their validity or considers them so unimportant that he does not deign to mention them. Dogmatic physicists further present things as though their theories and formulæ exhaustively covered the whole range of phenomena treated by them; they can see no further problems in this field, and thought and inquiry are ice-bound in their formulæ.

The aim of the pragmatic spirit is reality, and his way to this goal is appropriate and careful observation; the goal of the dogmatic spirit is the dogmatic formula, and his way is one of logical mathematical construction. For the pragmatic spirit physical research is a process of evolution from what has been established to new experimental knowledge; for him there is no such thing as classical physics or modern physics, but only physics. For the dogmatic spirit physics is a field for his logical formalistic activity towards revolution against existing principles and towards the accomplishment of general acceptance of his theories or, indeed, of his new 'world-picture' (*Weltbild*). The pragmatic spirit advances continuously to new discoveries and new knowledge; the dogmatic spirit leads to the crippling of experimental research, and to a literature which is as effusive as it is unfruitful and tedious, intrinsically akin to the theological dogmatism of the Middle Ages, which was opposed to the introduction of pragmatic natural science.

The researches of Lenard and of Rutherford present us with obvious recent examples of the manner in which the pragmatic spirit works in physics. By his experimental investigations on cathode rays, Lenard paved the way for the greatest discovery of the last fifty years, that of the electron, and furthermore, in the photo-electric effect, he revealed by careful measurements the connexion between the electron and light. From his intuitive sense of reality and by convincing experiments and measurements, Rutherford derived our knowledge of the radioactive transformation of chemical atoms and of their nuclear structure, knowledge which could never have been derived by dogmatic methods. The relativistic theories of Einstein, which are based on an arbitrary definition of space and time co-ordinates or their differentials, constitute an equally obvious example of a product of the dogmatic spirit. Another example of this kind is the wave-mechanical theory of Schrödinger. By an amazing feat of physico-mathematical acrobatics he obtains as a final result first a differential equation. He then asks what sort of physical significance the function that occurs in his equation may have, and for this he makes a suggestion, according to which the electron is arbitrarily smeared in a large spatial region round about the atom. In characteristic fashion, however, other dogmatic physicists (Born, Jordan, Heisenberg, Sommerfeld) give to the Schrödinger function another dogmatic significance, contrary to fundamental laws of experience. They make the electron dance round the atom in an irregular manner, and allow it to act externally as though it were simultaneously present at every point round about the atom with a charge corresponding to the statistical duration of its sojourn at each point.

There is still another important difference between the pragmatist and the dogmatist in physics, which has to do more with the characters of these two types. The physicist of the pragmatic spirit does not conduct propaganda for the results of his research in order to gain authority and influence; he finds his satisfaction in obtaining new knowledge and trusts that it will receive recognition from the expert as a representation of reality, and that it will serve as a step towards new advances. How different are the protagonists of the dogmatic spirit! They do not first wait for at least five years to see whether their revolutionary fashioned theories may perhaps prove to be inadequate or erroneous when examined in the light of experience. On the contrary, almost before they have been published, a flood of propaganda for them is started by articles in journals and newspapers, by text-books and by lecture tours, if possible right round the world. So far as I am aware, Rutherford never undertook lecture tours to make known the results of his researches. Of Lenard I know that he detested speaking about his researches before a wide public, and that he only twice took part in the German Congress of Natural Science (*Naturforscherversammlung*). On the other hand, older physicists will probably still remember with what pertinacity propaganda was carried on all over the world and before the widest public for Einstein's theories of relativity. Matters have not been quite so bad with the newer dogmatic theories which have been advertised under such terms as quantum theories, quantum mechanics, and so on; nevertheless, for the purpose of propaganda on their behalf, innumerable lectures have been held throughout the world, and very many text-books have been written about them.

In so far as the task of physics is the investigation of bodies and of laws concerning the reality of Nature, only the pragmatic attitude of men of science is qualified to solve them, and hence also alone entitled to do so. When the dogmatic spirit does not confine itself to theology and sociology, but also chooses physics as an arena for its intellectual gymnastics, one might tolerate this, but only under the condition that physical research of the pragmatic school of thought does not suffer in consequence. But for about three decades this condition has not been satisfied, at any rate not in Germany, where during this time the representatives of the dogmatic spirit have gained a dominating influence. By their collective action and their connexion with earlier Ministries they were able to acquire numerous chairs in physics, and above all in theoretical physics. In consequence of this, and because of the lively propaganda for modern dogmatic theories, academic youth was predominantly educated in the scientific ideal of the dogmatic spirit. Not men like Lenard and Rutherford, but Einstein and his dogmatic imitators were held up to them as models for scientific thought and work. I have taken the field against the dogmatic spirit in Germany because I have been able to observe repeatedly its crippling and damaging effect on the development of physical research in this country. In this conflict I have also directed my efforts against the damaging influence of Jews in German science, because I regard them as the chief exponents and propagandists of the dogmatic spirit.

This reference brings me to the national aspects of the mental outlook of men of science in research. It can be adduced from the history of physics that the founders of research in physics, and the great discoverers from Galileo and Newton to the physical pioneers of our own time, were almost exclusively Aryans, predominantly of the Nordic race. From this we may conclude that the predisposition towards pragmatic thinking occurs most frequently in men of the Nordic race. If we examine the originators, representatives and propagandists of modern dogmatic theories, we find amongst them a preponderance of men of Jewish descent. If we remember, in addition, that Jews played a decisive part in the foundation of theological dogmatism, and that the authors and propagandists of Marxian and communistic dogmas are for the most part Jews, we must establish and recognize the fact that the natural inclination to dogmatic thought appears with especial frequency in people of Jewish origin.

In establishing these facts, of course, I do not maintain that there are no Aryan men of science who are actively engaged in the dogmatic spirit in the realm of science; nor do I maintain that Jews cannot produce valuable experimental work carried out in the pragmatic spirit. I wish solely to make a statement on the frequency of occurrence of the natural tendency to pragmatic or to dogmatic ways of thinking. It must also be taken into consideration that, by training and practice, Aryans can become accustomed to the dogmatic and Jews to the pragmatic habits of thought. I acknowledge scientific achievement in new discoveries irrespective of the nationality of the discoverer, and I combat the harmful influence of the dogmatic spirit in physics whenever I encounter it in my scientific work, and regardless of whether the culprit is a Jew or not. Moreover, I have been engaged in this fight not only since 1933, for as long ago as the year 1922 I denounced in the strongest terms the formalism and dogmatism in German physics in one of my publications entitled: "The Present Crisis in German Physics".

Problems in the Oceanography of the North Atlantic

By C. O'D. Iselin, Woods Hole Oceanographic Institution, Woods Hole, Mass.

PROGRESS in our understanding of ocean circulation has generally been even slower than in some of the other branches of oceanography, in spite of the fact that in nearly every marine problem, both biological and physical, the current system plays a basic part.

At first the study of ocean currents was held back by the lack of accurate and convenient instruments. In more recent times, the expense of securing the observations has delayed the accumulation of adequate subsurface data on the distribution of temperature and salinity. If this were known in sufficient detail, it would probably not be a difficult task to settle several of the main problems which now confront physical oceanographers.

In particular, physical oceanographers have been unable to supply the climatologists and fisheries experts with the much-needed data on the variability of oceanic currents. Do ocean currents transport about the same amount of heat year after year, and are they, therefore, unimportant from the point of view of long-range weather forecasting? It is now known that changes in oceanic circulation have, on occasions, affected the fisheries of Great Britain; but it is not yet known if fluctuations in the strength of the Gulf Stream off the American coast bear any relation to fluctuations in the circulation of the water masses off the European coast.[1] Not only are such questions of considerable economic importance in some parts of the world, but also if the answers were known, it would be much easier to secure the necessary financial support to develop fully the science of oceanography.

For these reasons it is very encouraging that arrangements have been made during the past year for a co-operative programme of broad scope. The programme is to be undertaken jointly by the Bermuda Oceanographical Committee of the Royal Society and by the Woods Hole Oceanographic Institution. The Royal Society has obtained a generous grant from the British Government for the promotion of the scheme, and the Bermuda Biological Station is being developed as a base for the oceanographic work. The plan, which will shortly be in actual operation, involves the co-operation of the American oceanographers with the now increased staff of the Bermuda Biological Station; and the British grant, which covers a five-year period, also provides the Station with a much-needed research vessel.

The programme which has been suggested and on which work has already begun (June 1937) is essentially a continuation of modern oceanographic development, but it is hoped that it will be possible to stress those aspects of the investigation which now seem most likely to lead to the solution of the practical problems outlined above.

Three somewhat conflicting theories have been put forward to explain the mechanism whereby the changes in strength of the Gulf Stream could influence the fisheries of north-western Europe. The earliest and most popularly accepted belief concerning the influence of the Gulf Stream has the merit of logic and simplicity, but it is by no means certain that it is correct. This theory assumes that the Gulf Stream resembles a river of warm, saline water flowing north-eastward from the Florida Straits towards northern Europe, and that the current is variable. Thus, during years when it is stronger than normal, more warm water reaches the European coast to modify the climate and to alter the survival rate of young fish or to change the feeding grounds of the adults. In the light of recent oceanographic investigations, however, it is now known that the Gulf Stream bears little resemblance to a river of warm water. In fact, even off the American coast, only a very small part of the current is warmer than the surrounding seas, and after the current turns eastward and has passed the Grand Banks, the slight temperature maximum at the surface quickly disappears. For this reason, it now seems likely that only if the current changes very greatly in strength from year to year (and no sufficiently marked fluctuations have yet been observed) could it so directly cause a noticeable variation in the European coastal waters. Nevertheless, as will be explained later, the primary observations of the new project will attempt to follow the changes in strength of the Gulf Stream as it flows between Bermuda and the American coast during the next five years.

A second theory, which minimizes the importance of the Gulf Stream's influence on European waters, has been advanced more recently by Le Danois[2], a French oceanographer. He has pointed out that, on the whole, the North Atlantic Ocean can be subdivided into two great contrasting masses of water and that these do not readily mix. South of a line extending roughly from the Færoe Islands to the southern tail of the Grand Banks there is found a superficial, wedge-shaped layer of relatively warm and saline water which increases in thickness to 1,000 metres or more in lower latitudes. To the north at all depths, and elsewhere below the warm layer, is found a much greater mass of cold water of low salinity. Le Danois believes that the northern boundary at the surface between these two contrasting masses changes its location, depending either on variations in the volume of the warm layer or on a north-south shift of its mean position. An expansion or northward movement of the warm layer is termed a transgression and the opposite movement, a regression. Since the northern boundary of the warm layer is inclined towards the north-east, Le Danois believes that the main strength of a transgression is also expended in this direction and, therefore, that periodic variations are produced in the temperature and salinity of European coastal waters. He has collected evidence to support his theory that the transgressions come in cycles of increasing intensity having periods of 1, 4·6, 9·3, 18·6 and 111 years. Thus he has suggested that the periodicity is controlled by astronomical forces.

With some of the details of Le Danois' theory many oceanographers cannot agree, and especially they have ample evidence that the continuation of the Gulf Stream, better called the North Atlantic Current, cannot be disregarded. However, the northern branch of this current on the whole marks the northern limit of relatively warm water at the surface, and the main pattern of horizontal circulation in the North Atlantic is undoubtedly a huge clockwise eddy. Therefore, if the warm water at the centre of the eddy should increase in volume, or should its axis shift northward, the effect would be comparable to Le Danois' transgression theory. In other words, there is a possibility that changes in the amount or position of the warm-water core around which the North Atlantic eddy revolves and which it can be thought of as confining, may occasionally displace the current system of the north-eastern North Atlantic and thus cause marked and widespread variations near the European shore.

On the other hand, there is also the other possibility that the warm surface layer has a relatively constant volume and position, and this leads us through modern oceanographic principles to a newer theory that at the present time seems to have few drawbacks.

If we assume, as most investigators do, that the greater part of the energy which maintains the North Atlantic eddy comes from the trade winds, and if these should vary in strength from year to year, then the Gulf Stream, which is the most spectacular part of the eddy, would also vary in transport. If the current should increase, the Bjerknes[3] principle demands that the thickness of the central mass of warm water (the Sargasso Sea) should also increase. Therefore, unless the amount of warm water also increases, the diameter of the eddy must contract. In the same way, if the anticyclonic currents weaken, the dynamic height near Bermuda must decrease, which is another way of saying that the warm layer must become thinner. If this occurs, either the eddy must increase in diameter, or warm water must be discharged beyond the outer boundary of the surrounding circulation.

This line of reasoning leads to the idea that during periods of increasing strength of the Gulf Stream, the seas off the coast of Europe will become colder, instead of warmer, and that the reverse will happen during periods of decreasing oceanic circulation. This, of course, is exactly the opposite to the popularly accepted view. Since Bermuda is at approximately the centre of the main eddy of the North Atlantic, the new research vessel will easily be able to follow any changes in the thickness of the warm superficial layer. It can be confidently expected that as soon as this has been done over a period of a few years, it can then be shown which of these possibilities is correct.

Besides these supposed mechanisms involving variations in the intensity of the main horizontal currents, and expansions and contractions of the warm superficial layer of mid-latitudes, another basic theory has often been advanced. In this, the winds across the latitudes between the Grand Banks and northern Europe are considered the primary variable. If the surface water moves in the same direction as the wind, surface temperatures at a given point will rise during periods when southerly winds prevail and will fall with prolonged northerly winds.

Investigators, however, who are convinced by the theoretical studies of Ekman[4], which demand a net transport of the surface layer in a direction 90° to the right of the wind (for the northern hemisphere), will claim that it is easterly winds which cause increasing surface temperatures off the European coast. However this may be, it is clear that, provided the wind is sufficiently variable from year to year, wind currents in the surface layer can strongly influence surface temperatures. In fact, good arguments can be advanced to show that the variations in the strength and direction of the winds are a much more likely cause of changes in the European coastal waters than possible fluctuations of the oceanic circulation.

For the reasons outlined above, the programme of observations now being carried out in the neighbourhood of Bermuda and in the Gulf Stream involves two main investigations. First, the variability of the Gulf Stream will be examined with as much thoroughness as the available facilities permit, and secondly a detailed study of wind-produced movements in the surface layer will be made. In the Gulf Stream investigation the research vessel *Atlantis* of the Woods Hole Oceanographic Institution will play the leading part, while the smaller ship soon to be sent out to Bermuda, the *Culver*, will be chiefly engaged in examining the frictional effect of the wind on the sea surface. In addition, as already mentioned, she will make periodic observations to follow the changes in the thickness of the warm layer covering the central part of the Sargasso Sea. It is hoped that this dual programme will help to answer the question whether local winds or remote currents or a combination of the two are responsible for the variations in the physical characteristics of European coastal waters.

It may be of interest to discuss here some of the details of this five-year programme of observations. We will consider first the work the *Atlantis* began last June in the Gulf Stream. This current is so powerful and wide that an investigator with a single ship at his disposal is forced to use mainly indirect methods, for the technique of current-meter observations in deep water still remains unsatisfactory and time consuming. However, it cannot be stressed too strongly that the indirect methods should be supplemented as often as is practicable by direct observations of the strength of the current. The most reliable indirect method of measuring the volume of such a current as the Gulf Stream is to observe the vertical distribution of temperature and salinity at a number of stations spaced about twenty miles apart on a line crossing the current at right angles. From these observations the distribution of density can be calculated, and by applying the formula of Bjerknes the velocity and volume can be computed. While this method involves certain assumptions, on the soundness of which not all oceanographers are agreed, there is little doubt that should the current in this way be found to vary in strength over long periods by 20 per cent or more, the observations would impress even the most sceptical.

At the outset, therefore, the *Atlantis* has undertaken to occupy a section extending from Montauk Point on Long Island towards Bermuda at approximately monthly intervals. If this were to be continued for five years, practically the entire time of the vessel would be consumed and the mathematical computations would also be most laborious. However, in theory it is only necessary to observe the density of the water at two points on each side of the current, and this greatly simplifies the calculation of the volume of flow. As soon as the validity of this new shorter method can be established, the *Atlantis* routine observational programme will be greatly shortened.

The circulation theorem of Bjerknes is based on the principle that when a current in the northern hemisphere increases in strength, the sea surface must fall on its left hand side and rise on the right hand side. The relative changes in height of the sea surface on the two sides of the current can either be calculated from the subsurface distribution of temperature and salinity or can probably be observed by means of tide gauges. This method has not yet been given a thorough trial, but a comparison of the tidal records from

Bermuda and from the American coast has been made, and for years when subsurface oceanographic observations are available good agreement has been found. Thus it may well be that before long the *Atlantis* routine observations on the Montauk Point-Bermuda section can be very much curtailed or even entirely abandoned and the fluctuations in the strength of the current followed entirely through the tide-gauge records. The theory tells us that the surface of the Sargasso Sea is about 100 cm. higher than that of the waters north-west of the current. This difference in level will vary directly with the strength of the current. Thus an increase of 20 per cent should cause a rise of about 10 cm. at Bermuda and a corresponding fall on the opposite side, a change readily observed from the records of a properly located recording tide gauge.

This method should prove especially useful in the Straits of Florida, through which about a third of the ultimate volume of the Gulf Stream passes. Consequently the *Atlantis* has recently set out to install a tide gauge in the Bahamas, just across from Miami where the U.S. Coast and Geodetic Survey maintains a similar instrument. It is hoped that when these records are compared with the results obtained farther north, it will be possible to say whether or not the Gulf Stream as a whole increases and decreases in strength from year to year.

In the case of wind currents and the calculation of the exact coefficient of friction between the atmosphere and the sea surface, the observational difficulties are considerably greater. Several methods are in theory available. For example, the stress exerted on the water by the wind can be observed through the disturbance produced in the turbulent layer of either the sea or the atmosphere. It is a problem in which both meteorologists and oceanographers are equally concerned and to which the methods of both sciences can be applied. Unfortunately, in the past it has been found to be extremely difficult to secure sufficiently precise observations. The difficulty is partly instrumental, but it also results from the disturbance produced both in the water and in the air by a large research ship. In addition, wind currents can of course best be observed in regions where there are no permanent deep currents. It is hoped that the small vessel which is being sent out to Bermuda by the Royal Society will prove handier for this work than other ships that have already been tried out. Likewise, it is hoped that a region can be found not too far from Bermuda where the permanent currents are negligible.

It was first assumed that the stress exerted by the wind on the surface of the sea was probably proportional to the strength of the wind. But recently Rossby has presented evidence which indicates that there is a critical wind velocity below which the wind can get little grip on the water. He believes that this critical velocity is probably reached when the wind has a strength of about 15 miles per hour. If this can be demonstrated by satisfactory observations, then the surface movements produced by the winds can be calculated from the ordinary daily ocean weather maps and all winds less than the critical velocity can be neglected.

Moreover, there has recently been collected an increasing amount of evidence that the strength of the wind currents depends also on the stability of the surface layer. When the stability is great, apparently only a shallow layer is affected by the wind and the principle of Ekman's spiral perhaps breaks down. Thus if these matters can be more fully investigated, the wind currents for the practical purposes of this new programme can perhaps be neglected during seasons when the stability of the surface layer in mid-latitudes is very great due to the absorption of solar energy. Although the full magnitude of the problem can now be but dimly seen from the available observations, it is hoped that the calculation of surface movements from weather charts may not be insurmountable.

The possibility that there exists a critical velocity below which the coefficient of friction is extremely small leads us back to the variations in the strength of the Gulf Stream. As already mentioned, in all probability it is the energy absorbed from the winds across the latitudes of the trades which supplies the initial driving force for the current. If the trade winds vary slightly in strength over long periods and if the critical velocity falls within this range, then it is evident how the ocean can absorb much greater amounts of energy in certain years than in others. On the other hand, if the coefficient of friction is proportional to the wind velocity throughout the range met with in the trades, it seems unlikely that they can be the cause of important variations in the currents farther north.

In conclusion, we must frankly admit that the general outline of the Bermuda project given here will probably seem over-ambitious. However, if we had been able to go into more detail, it could have been shown that many of the special phases of the main problem are much less complicated and that the five years work that is planned will by no means fail if the main objectives prove to be hopelessly complex. When the twenty-odd investigations already started or planned are examined, it is evident that the chief strength of the whole programme lies in its attempt to encourage promising lines of investigation in physical oceanography. If several of these succeed, the entire effort will be justified. However, until physical oceanographers are able to show whether or not the surface layer of the ocean varies in temperature from year to year by a significant amount, they will get no peace from those who consider that science should have a practical objective. For this reason we hope we are justified in having attempted to explain how the work of the six or more cooperating investigators may eventually be fitted together. Let us hope that by such simple methods as observing the strength of the Gulf Stream in summer or by calculating the shift of the surface layer resulting from a prolonged spell of strong winds over the critical area west of Ireland, physical oceanographers will eventually be able to predict a mild winter or a good fishing season for northern Europe.

Obituary Notices

Mr. Edward Meyrick, F.R.S.

LEPIDOPTERISTS throughout the world will learn with deep regret of the death on March 31, in his eighty-fourth year, of Edward Meyrick, in his time the greatest authority and the most prolific writer on the Microlepidoptera.

At least so early as 1875, Meyrick published notes and new records, but in December, 1877, a post at King's School, Paramatta, N.S.W., provided him with greater opportunities for indulging his interest in collecting and studying Lepidoptera, of which during his ten years sojourn in the Antipodes he amassed an extensive collection. In the *Entomologist's Monthly Magazine* of August, 1878, he wrote :

> "I landed in December, the heat of summer, and have, therefore, only had half a year's collecting ; and as I had been prostrated during the last two months by an attack of low fever, I had only three months of actual collecting ; but I venture to assert that in the matter of *Micro-Lepidoptera* Australia stands pre-eminent among the nations [*sic*] of the earth."

Returning to Great Britain in January, 1887, Meyrick accepted the post, in the following September, of classics master at Marlborough College. This in no way hindered his entomological activities, and he was able to continue a series of contributions, commenced in 1879, to the literature of lepidopterology, unequalled in number and importance in the whole history of the subject.

In 1895 appeared his "Handbook of the British Lepidoptera", a remarkable achievement indicating his amazing energy and outstanding ability. Of this work J. W. Tutt (*Ent. Rec.*, 1895) wrote :

> "Mr. Meyrick's is probably the book of the year. It is the strangest jumble of advanced views and retrograde movement that has ever been published.
>
> "We have nothing but praise for the man who can step straight out of the old ruts, and produce a book which entirely upsets the treasured shibboleths of a school of entomologists, who were suckled on Newman and Stainton in their entomological babyhood, starved on Newman and Stainton in their manhood, and are still striving manfully to obtain nutriment from them in their old age. To such, if they see it, the book will be a revelation. But when one gets out of old ruts, one must know that the new road is sound and here our author is very doubtfully a trustworthy guide. The lines on which a new scheme of classification wants formulating must be compounded of the work done by specialists in various lines of work—Comstock, Dyar, Packard, Kellogg, Scudder, Chapman and Hampson are to hand. Instead of availing himself of all the material possible, our author chooses a path of his own, and neglects all the special work. Needless to say he often fails hopelessly. The unwieldy genera revert largely to the time when all butterflies were *Papilio*, all moths with pectinated antennæ, *Bombyx*, all 'Plumes', *Alucita*, and so on. In fact, the genera often comprise impossible combinations, and show the author to be utterly ignorant of the early stages of most of our British species. The book in detail is an utter failure ; yet in its broad aspects, we repeat again, that we have the greatest respect for the industry and pluck of the man who produced it."

This violent and badly expressed criticism was not altogether unjustified, and it is surprising that Meyrick, in the second edition published in 1928, again failed to avail himself of a number of facts that had been demonstrated by other authors, although he made some additions. The work was, however, no worse than that of many other authors right up to the present day, not excluding Tutt himself, and one example may be given to demonstrate the terrible muddle which even now exists in the genera of moths.

Boisduval (1828) erected a genus *Heliophobus* for *Noctua reticulata* Vill. (1789) and some other species, *N. reticulata* later being cited as type by Duponchel (1829). No notice has ever been taken of this, and *Heliophobus reticulata* has been placed successively in the genera *Hadena, Neuria, Mamestra* and finally by Meyrick in Hübner's genus *Melanchra*, with the type of which it is certainly not congeneric. Likewise *Noctua albicolon* Hubn. has travelled through the following genera : *Mamestra, Barathra, Luperina, Polia, Trichoclea*, finally ending up in *Melanchra* in

Meyrick's "Handbook" (1928), although it is a true *Heliophobus*. I do not hesitate to assert that this is by no means an isolated case among the British moths.

In the first edition of the "Handbook" (1895) appeared the *dicta* which have been called "Meyrick's Law": (1) No new organ can be produced except as a modification of some previously existing structure. (2) A lost organ cannot be regained. (3) A rudimentary organ is rarely redeveloped. It strikes me as strange that Meyrick should have reprinted these statements without modification after thirty-two years. One would have preferred the following modifications: (2) A lost organ is not regained. (3) A vestigal organ is rarely redeveloped.

In 1912 Meyrick commenced a separate publication of his own which he called *Exotic Microlepidoptera* and described as "a spasmodic entomological magazine on one subject by a single contributor". In his original preface Meyrick wrote:

> "The purpose of this volume is to ensure the speedy publication of material which is required for immediate use in other works proceeding at the same time, especially in my contributions to the *Genera Insectorum* and *Lepidopterorum Catalogus*; the delays incidental to publication through other channels would otherwise involve so much arrangement in advance as to seriously hamper the work."

Up to September, 1936, four volumes had been completed, running to some 2,500 pages in all, and during the next twelve months 160 pages of vol. 5 had appeared.

Latterly, Meyrick collaborated with Prince Aristide Caradja, the distinguished Roumanian lepidopterist, in a number of important papers on the Palæarctic Microlepidoptera (including Pyralidæ), with some valuable contributions to our knowledge of the Chinese fauna.

For many years Meyrick had identified Microlepidoptera and Pyralidæ for the Imperial Institute of Entomology. He was a very quick worker, a delightful correspondent and he rarely kept a colleague waiting long for identifications, always describing at once any new species.

I was pleased to note the impression made upon Meyrick, who was a man of very conservative views, by Wegener's theory of continental drift, even before the more recently collected evidence in support of it had been brought forward.

Meyrick was elected a fellow of the Royal Society in 1904. He had been a fellow of the Royal Entomological Society of London since 1880.

It is gratifying to learn that Mr. Meyrick's extensive collection, the value and importance of which it is impossible to estimate, is bequeathed to the British Museum (Natural History).

W. H. T. Tams.

An anthropological correspondent writes:

For many years Mr. Meyrick was responsible for the records of anthropometric measurement of the Marlborough boys, on which he prepared the reports appearing in the publications of the Marlborough College Field Club. When the Inter-Departmental Committee on Physical Deterioration, which reported in 1904, was sitting, the lack of exact evidence relating to the trend of physical development in the child and adolescent population of Great Britain was a grave drawback; but the Marlborough records, being almost the only material available for comparative purposes extending over any considerable period of time, afforded information of the greatest value for the inquiries of the Committee. It was mainly on this material that the Committee based its finding that the public school population, at least, showed no evidence of the alleged physical deterioration in the population at large, into which the Committee was appointed to inquire. The absence of exact data respecting the physical development of the school population of England and Wales was one of the decisive factors in bringing about the passing of the Act of 1907 for the medical inspection of school children; though much to the disappointment of many who were among its strongest supporters, it was not considered practicable to introduce into the elementary school a scheme of anthropometric measurement of a more extended character.

Dr. G. B. Grinnell

The death is reported of Dr. George Bird Grinnell, distinguished as geologist, naturalist and ethnologist, which took place in New York on April 11 at the age of eighty-nine years.

Dr. Grinnell was born on September 20, 1849, and educated at Yale University, where he graduated in 1870, proceeding to the degree of Ph.D. in 1880, and being awarded the D.Litt. in 1921. In 1870 he began his study of the Plains Indians, one of the activities for which he became most widely known. He was long recognized as the foremost authority on the history and customs of the Blackfeet, Pawnee and other Plains Indians, so that his appointment as Special Commissioner for the sale of lands to the Blackfeet and Fort Belknap Indians in 1895 was natural, and indeed inevitable. From 1874, when he joined the staff of the Peabody Museum as assistant osteologist, until his retirement in 1911, he was attached to this Museum or to the staff of Yale University. He was extremely active in collecting fossils and other specimens for the Museum, and took part in several expeditions, among them that to the Black Hills in 1874, the Yellowstone Park Reconnaissance expedition in 1875, expeditions to the Plains and the Rocky Mountains on behalf of his Museum, and the Harriman expedition to Alaska in 1899. Grinnell was the first in America to take action against the wholesale destruction of wild fowl and game, and his love for wild life in all its forms led to the foundation of the Audubon Society. For some years he was chairman of the Council on National Parks, Forests and Wild Life, and in 1925 succeeded President Hoover as president of the National Parks Association. In the same year he was awarded the Roosevelt Distinguished Service Medal for his lifetime's devotion to outdoor life.

News and Views

The "Jewish" Spirit in Science

IN July of last year, several correspondents sent us copies of an article entitled " 'Weisse Juden' in der Wissenschaft", from the German periodical *Das Schwarze Korps* of July 15. The main theme of the article was that it was not sufficient to exclude all Jews from sharing in the political, cultural and economic life of the nation, but to exterminate the Jewish spirit, which is stated to be most clearly recognizable in the field of physics, and its most significant representative to be Prof. Einstein. "There is one sphere in particular," the article says, "where we meet the spirit of the 'White Jews' in its most intensive form and where what is common between the outlook of the 'White Jews' and Jewish teaching and tradition, can be directly proved, namely, in *Science*. To purge science from this Jewish spirit is our most urgent task. For science represents the key position from which intellectual Judaism can always regain a significant influence on all spheres of national life. Thus it is characteristic that in a time which brings fresh tasks to German medicine and which awaits decisive achievements in the fields of heredity, race-hygiene and public health, our medical journals should, in the space of six months, publish from a total of 2,138 articles, 1,085 from foreign authors, including 116 from Russians of the U.S.S.R. These articles of foreign origin scarcely concern themselves with those problems which seem so urgent to us. Under cover of the term 'exchange of experience' there lurks that doctrine of the internationality of science which the Jewish spirit has always propagated, because it provides the basis for unlimited self-glorification."

Prof. Stark's Views

SEVERAL men of science of international reputation were named in the article as followers of Judaism in German intellectual life, and it was remarked that "They must be got rid of as much as the Jews themselves". *Das Schwarze Korps* invited Prof. J. Stark to express his opinion upon this suggested purge on account of "the importance of the problem for the future of German scientific work". After reading Prof. Stark's reply, we asked him if it represented his considered views upon the relative values of experimental and theoretical studies; and if so, whether he would care to make them known to other men of science through the columns of NATURE. He willingly consented to contribute the article, of which a translation appears elsewhere in this issue. At the moment we make no comments upon the views expressed by Prof. Stark; and we gladly give him the opportunity of making them known to the scientific world. We should, however, be surprised if the limitations which these new principles impose on the pursuit of scientific truth are generally accepted as the highest or the best means of promoting the advancement of natural knowledge.

James Watt International Medal

To commemorate the bicentenary of the birth of James Watt on January 19, 1736, the Institution of Mechanical Engineers of Great Britain decided to award every two years a Gold Medal to an engineer of any nationality who is deemed worthy of the highest award the Institution can bestow and that a mechanical engineer can receive. In the making of the award the Institution has secured the co-operation of engineering institutions and societies in all parts of the world. To be worthy to receive a medal struck in commemoration of one who was at one and the same time a scientific investigator, an inventor and a producer, the recipient himself should be an engineer who has achieved international recognition both by his work as a mechanical engineer and by the ability with which he has applied science to the progress of mechanical engineering. The Institution recognizes, however, that only rarely will it be possible to find men in whom these qualities are so equally balanced as in James Watt. It will, therefore, consider men who have attained world-wide eminence in mechanical engineering in any direction—science or research, invention or production. After considering the recommendations of mechanical engineering societies in leading industrial countries throughout the world, the Council of the Institution of Mechanical Engineers has unanimously decided to make the second award of the James Watt International Medal to Mr. Henry Ford of Detroit, U.S.A., nominated by the American Society of Mechanical Engineers. The first award was made in 1936 to Sir John Aspinall, who unhappily died before the actual presentation was made.

Henry Spencer Palmer (1838–1893)

ON April 30 occurs the centenary of the birth of Major-General Henry Spencer Palmer, a distinguished British military engineer who did important work in various parts of the world. The son of a colonel, he was born at Bangalore, Madras, and after passing through the Royal Military Academy, Woolwich, entered the Royal Engineers in 1856. From 1858 until 1863 he was engaged on the survey of British Columbia. On his return he joined the Ordnance Survey and in 1867 took part in the parliamentary boundaries commission appointed under Disraeli's Act of that year. His next work was the survey of the Sinai Peninsula, and in 1873, through Airy, he was appointed chief astronomer of the expedition sent to New Zealand to observe the transit of Venus of 1874. While at the Antipodes he assisted the French to determine the longitude of the Campbell Islands. He returned to England in 1875, and three years later was sent to Hong Kong as chief engineer of the Admiralty works. While there he designed a physical observatory for astronomical, magnetical, meteorological and tidal observations, and he made exact determinations of the position of the Hong Kong Observatory at Mount Elgin, Kowloon. In 1882, on his way home, he prepared a scheme for waterworks for Yokohama. This had been done at the request of the Japanese Government, and in 1885 he returned to the East to superintend the work. He also designed works for Osaka and Hakodate. He retired from the British Army in 1887 with the rank of major-general and died at Tokyo on March 10, 1893, at the comparatively early age of fifty-four years.

Research on Influenza

The Medical Research Council has published a long report of the investigations made by Dr. C. H. Andrewes and his colleagues into the influenza epidemic of 1936–37 (Medical Research Council, Special Report Series, No. 228. London: H.M. Stationery Office, 1938. 2*s*. 6*d*. net). They have amply confirmed their previous discovery that there is an acute disease which may be properly called 'influenza', due to a virus which is specially infective for ferrets, and that many outbreaks of a somewhat similar kind are not associated with the virus; these they call "febrile catarrhs". Much attention was given to the possibility of diagnosing the real influenza by clinical means, and with a certain amount of success, though it is clear that accurate differentiation without demonstration of the virus is still rather uncertain. They have also confirmed the disconcerting American finding that all strains of the virus are not antigenically the same. Their plans for large-scale trials of preventive inoculation were anticipated by the epidemic, which came earlier than was expected and made a muddle of the experiments; so far as they went, however, they did not show that inoculation was of any preventive value. Nor did the few cases which were treated with an anti-serum derive much benefit. In these respects, therefore, the results are disappointing, though a good deal has been done towards obtaining greater success in the outbreak which may be expected next winter.

The Earthquake in Anatolia

On April 19, a destructive earthquake occurred in central Anatolia. Its epicentre lay near Kirshehir, about 90 miles south-east of Angora, and in this district ten villages were completely destroyed and at least 200 persons were killed. In Yozgad, about 60 miles north-east of Kirshehir, much damage was also caused, but the loss of life was small. The disturbed area extended from the Black Sea nearly to the Mediterranean. The first vibrations reached London at 12.11 p.m., and the earthquake must therefore have occurred shortly before 2.30 p.m., local time, when most of the inhabitants were at work in the fields. Since the beginning of the eighteenth century, not less than thirty-one great destructive earthquakes (of intensity 3, Milne scale) have occurred in Turkey in Asia, with one exception either in the west of the country about Smyrna and Broussa or in the east about Erzeroum and Diarbekr. The central portion of the country has been comparatively undisturbed. From Miss Bellamy's "Catalogue of Earthquake Epicentres" we find that during the years 1913–30 there were six earthquakes in three centres near Kirshehir and Yozgad, though none was strong enough to be recorded more than 80° from the origin. In 1902, however, there was a destructive earthquake at Kastamonu, about 150 miles north of Kirshehir, of about the same intensity (degree 3) as the recent earthquake.

The Magnetic Storm of April 16

In the note on the great magnetic disturbance of April 16 as recorded at Abinger Observatory, printed in Nature of April 23, p. 721, it was only possible to give tentative estimates of the range in declination and horizontal intensity, for reasons then stated. Critical examination of the traces has since been made which confirms the estimate for declination but considerably reduces the figure given for horizontal intensity. The definitive ranges in the three elements are now stated, with the times of maximum and minimum, as below:

	Range	Maximum at	Minimum at
Declination (west)	5° 7′	6h. 15m. U.T.	7h. 50m.
Horizontal intensity	1880γ	7 54	7 21
Vertical intensity	494γ	7 52	7 36

York Museum of "Bygones"

The Castle Museum, York, of which the nucleus is the collection of Yorkshire "Bygones" formed by Dr. J. L. Kirk, of Pickering, was formally declared open by Lord Middleton, lord lieutenant of the East Riding, on April 23. The Museum is housed in the eighteenth century buildings, formerly the female prison, of York Castle, which, with the exception of the medieval Clifford's Tower, vested in H.M. Commissioners of Works under the Ancient Monuments Acts, is now in the possession and under the control of the Corporation of the City of York. The Corporation will be responsible for the maintenance of the Museum, and the sum of £8,000, in addition to two grants of £500 each from the Carnegie Trustees and the Rowntree Trustees, has been expended on the installation. The exhibits, including a Tudor half-timbered house and fifteen shop-fronts in two and three storied houses flanking a cobbled street, illustrate the life, domestic, commercial and industrial, of Yorkshire over a period of two centuries ending with mid-Victorian times. Among the more striking and characteristic features are old hearths and their furniture and old agricultural implements and horse-brasses. By a judicious arrangement with the former owner, the Corporation has retained the right to enlarge the collection with the view of making the exhibits illustrate as fully as possible the old-time life of the folk of Yorkshire. An annexe, for example, is to be added shortly, which will house specimens of old and obsolete vehicles. As was pointed out at the opening ceremony by Dr. Mortimer Wheeler, president of the Museums Association, the Castle Museum is a valuable addition to the all too scanty collections, which illustrate the past social life of England.

Science and the Home

THE great variety of material that the glass industry is now able to place at the disposal of the architect and the builder is well demonstrated by the 'Glass Hall' erected in the *Daily Mail* Ideal Home Exhibition at Olympia, which closes on April 30. The exhibits showed that in the hands of artist-craftsmen glass can be made a most effective medium of decoration. As regards the Glass House itself, the light-diffusing outer walls were made of fluted glass bricks permitting no observation from the outside. A partial vacuum inside renders them useful for the insulation as regards heat and sound. Each of the rooms of this house exhibits phases, useful and decorative, of the possibilities in glass, and the Crystal Kitchen has glass walls on two sides with the great merits of giving plenty of light and of being very easily kept clean. The Glass Train brought into Addison Road Station for the Exhibition, is, in a way, even more striking, as throughout it the walls, floors and ceilings are of glass. It is an exhibition in itself and includes examples of the 'Insulight' glass bricks mentioned above and of the Armour-plate glass, specially heat-treated so as to possess great fire-resisting properties with high mechanical strength. It can be bent through 30° without breaking and will withstand a range of temperature from − 70° C. to + 300° C. The numerous fittings and other features represent nearly six hundred different varieties of glass. In another branch of industry the domestic possibilities of 'Staybrite' in pans, sinks, door furniture, toilet fittings and table-ware are demonstrated. The strength and wearing properties of this and similar materials must inevitably prove their superiority in the home. Then for the purpose of keeping food fresh and cool, one of the oldest principles for the production of long-sustained low temperature is employed in the 'Kepkold' series of coolers. By keeping the surrounding absorbent tiles supplied with water the cooling effects of evaporation are obtained without recourse to the more expensive refrigerators the utility of which depends on a supply of electricity or gas.

Optical Projection of Surgical Operations

AN optical apparatus of some interest to surgeons, devised by Profs. H. Costantini and L. Verain, of the University of Algiers, has recently been produced by the firm of Barbier Bénard and Turenne, 82 Rue Curial, Paris. It is termed a 'Scialyscope' and is a development of the shadowless light now installed in many operating theatres. It consists essentially of a conical reflector nearly 2½ metres in diameter, and of roughly parabolic form, by means of which the rays from a very powerful light-source are concentrated on the field of operation. Beneath the lamp itself is placed an optical system containing a large right-angled prism by which an image of the field of operation is formed on a translucent screen in an adjoining room. The magnification on the screen is 3½ diameters, and the illumination is so powerful that a spectator at a distance of seven metres can obtain a brilliant view of every detail in the field of operation. There has always been very great difficulty in demonstrating operative details to a group of students; their mere presence in an operating theatre is undesirable, and it is obviously impossible for most of them to obtain any but a fleeting glimpse of what is happening. With this apparatus forty or fifty students in an adjoining room can easily follow every detail, and it will be noted that their view is obtained from a point immediately above the field of operation. By means of a microphone and a loud speaker, the surgeon can describe to them at the same time all that is being done. The method would appear to have considerable possibilities and it certainly overcomes the difficulties involved in demonstrating operative details to a number of individuals.

Report of the University of Birmingham

IN his seventeenth and last report to the Council, presented at the annual meeting of the Court of Governors of the University, the Vice-Chancellor (Sir Charles Grant Robertson) gives a summary of the progress of the University during his tenure of office. In 1920 "the high hopes, the vaulting ambitions and the dreams of a golden dawn that inspired a Great Britain freed by the Armistice from the terrors and horrors of the War slowly faded away or were frozen out, and in their place came spiritual and moral anarchy and the cynicism derisive of the past, and baffled by the present, that fears nothing but the future". Since then the University has gone rapidly forward. The income and expenditure in 1921 were £143,631 and £144,535 respectively, while for 1937 they were £232,690 and £230,805, not taking into account the sums for fellowships, scholarships and other trust funds which pass through the accounts of the University. Assets have increased to £2,199,306, and the University is free from debt, the contributions to the endowment since 1920 being not less than £930,000. The grants from local authorities have increased from £11,887 to £33,570. Expenditure in stipends has increased from £34,131 to nearly £100,000. There are now 34 full-time professors and 10 part-time, while the non-professorial staff now numbers 297. The Library grant has been quintupled and the number of readers and of books taken out has increased eightfold. "The function of a university library is not merely to satisfy existing needs, but to create new appetites as yet unknown and always unpredictable; you never can tell what may result from the contact of a young mind with an adequately equipped library. In a university more minds than we are aware of are always at flash-point. It is the spark that is so often wanting."

SIR CHARLES notes with satisfaction the success which has attended the large measure of self-government which has been given to the undergraduates—"the student body has justified the confidence that the unification of responsibility with power demands". He wishes, however, that a really serious share in these activities were not left to an able but overburdened minority, and to a still smaller but very vocal opposition who find in the Vice-Chancellor and 'the authorities' the source of all their troubles. "But that is almost inherent in all 'day universities' in huge cities where two hours or more have to be spent daily in coming and going. It may require another generation to pass before the truth that a university education is a life together and not merely a learning together is grasped by every fresher at entry." The number of students which showed a steady increase until 1933–34 has since shown a progressive though small decline. This decline is viewed with some anxiety and is regarded as probably due to the fall in the birth-rate, the forecast being made that by 1955 the number of students may have fallen to not more than 1,200 or 1,300, or perhaps less. It is noted that about 45–50 per cent of the students hold scholarships or grants from public funds which enable them to take a university course, and that about 48 per cent started their education in an elementary school.

Obstacles to Teaching

In her presidential address on April 16 to the National Union of Teachers, Mrs. E. V. Parker, a teacher in a London County Council school, dwelt on those unfavourable conditions which hamper the work of teachers eager to contribute to the salvaging of civilization. The generous ideals of the Hadow Report, foreshadowing the elimination of social class distinctions in a unified system of public education and "freedom for every child to attain its full stature", have not been realized; nor can they be without provision by the community of proper material environment in school and home and drastic reduction of the size of classes. The freedom of the teacher is threatened with partisan interference which seeks "to sap and undermine by labelling many of our positive educational activities as propaganda". In the junior school the incubus of the external examination from which elementary schools were rescued in 1895 has reimposed itself as an instrument for selection for free secondary school places, which should be the birthright of every British child. In the new senior schools a large measure of freedom is enjoyed, but they need levelling up to the standard of the older secondary schools in point of leaving age, staffing and amenities. Meanwhile, it is essential that the last months before the child leaves school should be devoted to an earnest effort to gather up the loose threads of knowledge, to give meaning to all the work already done, making plain its applicability to the problems of life and providing the stimulus that will result in a continuance of interest and effort for self-education.

Japanese Nationalism and Intellectual Freedom

Japan won her high place among world powers in little more than a generation by a will to accept and assimilate ideas from outside her own culture, which was a cause of wonder and admiration among all civilized peoples. It is, therefore, all the more remarkable that this liberal attitude should now have been abandoned in favour of a spirit which interprets the springs of nationalism in the narrowest sense. A commission, it is reported by the Tokyo correspondent of *The Times* in the issue of April 21, is engaged in investigating the books in use in the universities of Japan with the view of determining whether they are fully in accord with the national spirit. Among books which it has been decided to ban are Mill "On Liberty", Bertrand Russell's "Roads to Freedom", George Gissing's "Private Papers of Henry Ryecroft", "Tess of the D'Urbervilles" by Thomas Hardy and "Ulysses" by James Joyce. The choice might seem peculiar, and, in fact, to English-speaking peoples almost capricious, even when it is added that the principles of selection exclude all books which encourage liberalism, offend morals, describe excessive cruelty, or whose authors have attacked Japan. With the exception of the ground last-named, which may or may not be regarded as excusable, such a policy seems not only over solicitous for the intellectual weakling, but even admirably calculated to produce the stunted judgment which in the long run will make for national weakness rather than strength.

The London Television Service

The paper on the London Television Service read to the Institution of Electrical Engineers on April 21 by T. C. Macnamara and D. C. Birkinshaw describes the television station recently built by the British Broadcasting Corporation in a part of the Alexandra Palace, London, N. The reports of the reception of the transmissions have in general been encouraging. The range of the station, originally estimated to be about 25 miles, has proved to be considerably farther in most cases; good reception can be obtained up to about 35 miles. Reports of visual receptions have been received from Brighton, Southend, Cambridge and Bedford, the distances of which from the station are 40–60 miles. In these cases reception took place under exceptionally favourable conditions. It has been found that in the ultra-short waves used for television, the interference due to electro-medical apparatus used for high-frequency diathermy is sometimes serious. For example, a North London hospital situated about half a mile from the Alexandra Palace has a spark diathermy machine which when used completely 'jams' the reception of the five-metre radio link transmitter at the Palace. The whole of the walls and ceiling of the room were covered with aluminium foil 5 mm. in thickness, applied with a paper backing after the fashion of ordinary wall paper. At one end of the room, which was open, a partition covered with ½ in. mesh chicken wire was erected and good electrical connexion made between the aluminium foil on the ceiling and walls and the chicken-wire. A similar screen was placed over the window and another was laid on the floor underneath the usual rubber floor material. The treatment effected complete suppression of the interference. If the screened door in the partition was opened by only a few inches, the interference was almost as bad as with the unscreened room. This proves the necessity of taking thorough measures.

A Bird New to Great Britain

An interesting addition to the British bird list is described by H. F. Witherby in the March issue of *British Birds*, namely, the first identified specimen of the western little bustard (*Otis tetrax tetrax*). This specimen was one of two "strange birds" shot during a partridge drive at the Wadworth estate of Yorkshire, just south of Doncaster, so far back as December 9, 1922. The shooting tenant presented the specimen to Capt. E. W. S. Foljambe, who had it preserved at Osberton, Nottingham, whence he recently sent it to London for expert study. The whereabouts of the second bird shot on that date have not been traced. The western race of the little bustard inhabits Spain, Portugal, France and north-west Africa, and differs from the eastern race in the possession of more sandy-buff colour on the upper parts and wing-coverts, in having the black markings less pronounced, and the vermiculations finer. The eastern little bustard (*Otis tetrax orientalis*) had previously been recorded in Great Britain, and the specimen was at first thought to belong to that race. One was shot at Addlethorpe, Lincolnshire, in November 1933, another in Kincardineshire in 1912, one near Peterhead, Aberdeenshire, in January 1935 and one in Hampshire during a partridge drive in December 1935.

Journal of the Glasgow Mathematical Association

We have only just received the first two numbers of this journal, although the first appeared so long ago as December 1936, and the second a year later. The Glasgow Mathematical Association is the successor to the "Euclidean Society" formed in Glasgow in 1927. Its objects form a curious contrast with those of the well-known Mathematical Association, which is the successor to "The Association for the Improvement of Geometrical Teaching". The objects of the latter might be described as revolutionary, in the first place to break away from the shackles of Euclid, and then to break away also from the traditional methods of teaching algebra, trigonometry and other branches of elementary mathematics. The Glasgow Association, on the other hand, is counter-revolutionary. Its original object was to adhere to Euclid's methods whenever the substitutes were considered unsatisfactory. An article by J. McWhan pleads also for a return to the "uninspiring but fundamental topics" in algebra and trigonometry, and claims that "the drill itself, and the concentration and self-discipline implied in it, are surely of the highest educational value", although "not in itself stimulating or pleasurable either to pupil or teacher". These views are supported by evidence as to the bad effects of modern methods of teaching.

The *Journal* may be warmly recommended even to those teachers who do not consider that what is pleasant is probably evil. There are interesting historical articles on Stirling and Monge, and a most valuable exposition of the "Intuitionist" point of view concerning the nature of mathematics. This, if accepted, would necessitate a drastic pruning and remodelling of the whole of abstract function theory, such as the Heine-Borel theorem, and would reject the theory of non-enumerable classes and Lebesgue measure as merely "verbal mirages". There is also an article on compass constructions, and notes on the teaching of geometrical progressions, medial section, the construction of triangles, the sums of powers of the natural numbers, and the binomial theorem.

Plague Research in India

In the report of the Haffkine Institute, Bombay, recently issued, the Director, Lieut.-Colonel Sokhey, summarizes the work of the Institute during 1936. It is the centre for the manufacture of plague vaccine for the whole of India, and more than 800,000 doses of vaccine were issued during the year. Much work has been done on the standardization of the dose of virulent plague bacilli for measuring the protective power of plague vaccines, and upon the preparation of a potent anti-plague serum for treatment. Investigations on the epidemiology of plague have shown that the house rat in some localities is resistant to plague, but that in them the small field rat is highly susceptible, and is probably responsible there for the spread of the disease.

The Night-Sky in May

The moon is full on May 14^{d} at $8{\cdot}6^{h}$ and new on May 29^{d} at $14{\cdot}0^{h}$ U.T. At full moon, a total eclipse of the moon occurs, but this is invisible from Europe. At new moon on May 29, a total eclipse of the sun takes place, but this phenomenon is likewise invisible from Europe, the path of totality lying in the southern part of the South Atlantic Ocean. The sun will be seen partially eclipsed from South Africa and the southern part of South America. Amongst the occultations visible from Greenwich this month may be noted the following: on May 2 at $20^{h}\ 5{\cdot}1^{m}$ the disappearance of 106 Tauri (mag. 5·3); on May 3 at $20^{h}\ 41{\cdot}8^{m}$ the disappearance of 68 Orionis (mag. 5·7); on May 12 at $20^{h}\ 57{\cdot}2^{m}$ the disappearance of B.D.—15° 3817 (mag. 5·1) and on May 17 at $1^{h}\ 39{\cdot}0^{m}$ the reappearance of 58 Ophuichi (mag. 4·9). Of planetary phenomena to be looked for is the unusually close approach of Venus and Mars on the evening of May 7, the actual conjunction taking place on May $8^{d}\ 0^{h}$, that is, about $2\frac{1}{4}$ hours after the planets have set below the horizon at Greenwich. Binoculars should be used to see this interesting phenomenon, and the difference in colour of the two planets will be observed. On May $1^{d}\ 19^{h}$ and May $31^{d}\ 16^{h}$, Venus is in conjunction with the moon; on May $2^{d}\ 1^{h}$ and May $30^{d}\ 18^{h}$, Mars is in conjunction. Jupiter, a morning star, is in conjunction with the moon on May $22^{d}\ 17^{h}$. In the middle of the month at 21^{h} a very interesting region of the sky is on the meridian. This region contains an assembly of nebulæ in Virgo and Coma Berenices and the loose cluster of bright stars that form the mythical tress of hair of Berenice. East of this cluster is the north galactic pole, in the direction of which the 100-inch telescope has explored the remote extra-galactic nebulæ to a distance of more than 500 million light years. Hubble states that, on long exposure plates taken under good conditions with the 100-inch reflector, the recognizable nebulæ in the direction of the galactic poles average about 2,400 per square degree and are more numerous than the stars!

Announcements

THE Gold Medal of the Royal Society of Medicine, given triennially in recognition of services to the science and art of medicine, has been awarded to Prof. Wilfred Trotter, director of the surgical unit at University College. Prof. Trotter is the seventh recipient of this medal, his predecessors having been Sir Almroth Wright, Sir F. Gowland Hopkins, Prof. J. S. Haldane, Sir Henry Head, Sir Thomas Barlow and Sir Archibald Garrod.

THE Gold Medal of the Institution of Mining and Metallurgy has been awarded to Prof. S. J. Truscott, "in recognition of his services in the advancement of the science and practice of mining and metallurgy, with special reference to his services in technological education". The Consolidated Gold Fields of South Africa, Ltd. Gold Medal has been awarded to Prof. H. V. A. Briscoe, "in recognition of his researches on the sampling and properties of industrial dusts"; The Consolidated Gold Fields of South Africa, Ltd. Premium of forty guineas has been awarded conjointly to Dr. Janet W. Matthews, Mr. P. F. Holt, and Miss Phyllis M. Sanderson, "in recognition of their work, in association with Prof. H. V. A. Briscoe, on the sampling and properties of industrial dusts".

THE following have been elected members of the Royal Danish Academy of Sciences and Letters, Copenhagen: Prof. Einar Lundsgaard, Copenhagen; Prof. H. O. Eilert Ekwall, Lund; Prof. Didrik Arup, Seip; Prof. V. M. Goldschmidt, Oslo; Prof. Haaken H. Gran, Oslo; Prof. Theodor Frings, Leipzig; Prof. Albrecht Götze, New Haven; Prof. R. L. Enno Littmann, Tübingen; Prof. Richard Goldschmidt, Berkeley; Dr. Peyton Rous, New York; Prof. August Thienemann, Kiel.

PROF. ALEXANDER W. EVANS, Eaton professor of botany in Yale University, known for his work on the Hepaticæ (liverworts), celebrates the seventieth anniversary of his birthday on May 17. A dedicatory volume of *Annales Bryologici* is being prepared to mark this occasion. This "Festschrift" contains a biographical notice and portrait of Prof. Evans together with about twenty-five contributions from leading American and European bryologists and hepaticologists.

AT a meeting of the Royal College of Physicians of London held on April 11, Dr. Robert Hutchison, consulting physician to the London Hospital and to the Children's Hospital, Great Ormond Street, was elected president in succession to Viscount Dawson of Penn.

A GENERAL COMMITTEE, consisting of the Council of the Royal Society of Edinburgh and a number of leaders in science and education, has been formed to further the project of securing a portrait of Sir D'Arcy Wentworth Thompson, president of the Society, to be hung in the Society's Rooms. The portrait is being painted by Mr. David S. Ewart. Dr. James Watt is treasurer of the Fund, and will be glad to acknowledge any remittances sent to him at the Society's Rooms, 22 George Street, Edinburgh, 2, marked "R.S.E. President's Portrait Fund".

MR. H. F. BROADBENT left Port Darwin on April 17 and flew to Lympne arriving at 10.51 on April 22, the actual flying time for the journey being 5 days 5 hours 21 minutes. He thus beat the record previously held by Miss Jean Batten by 12 hours 54 minutes.

AT its last general meeting, the Vienna Biological Society elected Profs. Harvey Cushing of New Haven, U.S.A., Sir F. Gowland Hopkins of Cambridge and C. G. Santesson of Stockholm as honorary members, and Profs. A. v. Muralt of Berne, G. Bayer of Innsbruck, H. Guggisberg of Berne, Barkar of Tartu and Anrep of Cairo as corresponding members.

THE Jugoslav State has allotted a sum of four million dinars to the Jugoslav Society for the Social and Scientific Campaign against Cancer to enable a cancer institute to be founded at Belgrade.

ON the occasion of the eightieth birthday of King Gustav V of Sweden on June 16, a Swedish fund will be organized for the investigation and control of common diseases, especially poliomyelitis and rheumatic disorders.

THE Vienna Sectional Meeting of the World Power Conference will, notwithstanding recent political events, be held on August 25–September 2, 1938, and the programme remains unaltered. At the recent annual general meeting of the British National Committee, it was decided to proceed with preparations for British participation in the Vienna meeting. Sir Harold Hartley has again been elected chairman of the British National Committee of the World Power Conference, to serve for a further term of three years.

THE lecture entitled "Some Carbohydrate Problems" arranged to be given by Prof. W. N. Haworth before the Chemical Society on May 5 at 8 p.m., has been postponed. Instead, Prof. J. Masson Gulland will deliver a lecture on "Nucleic Acids".

THE writer of the article on the "Teaching of Technical Optics" in NATURE of April 9, p. 654, regrets that by inadvertence he omitted the firm of Messrs. Aldis Brothers from among the makers of photographic lenses. This firm has made photographic lenses since 1902; it has a Cambridge graduate as designer and is, of course, well known for the high quality of these lenses. The name of the firm was mentioned in the article among those of other firms which have devoted particular attention to the design of lens systems.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 793.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Social Relations of Science

ABSENCE abroad has prevented me from responding sooner and expressing, as invited, an opinion on the proposals in the article entitled "Social Relations of Science" printed in NATURE of April 23. Though to me they come too late and too tainted with officialdom and regimentation to appear to be much more than a wish to be in at the shouting, it would be churlish not to express gratitude that they are, at least, explicit and capable of being intelligently discussed.

The effect of scientific discovery on the whole framework and content of sociology, economics and politics has been with me a major preoccupation for nearly twenty years. In that time, I have had the satisfaction of seeing grow from very small beginnings what is no exaggeration to say is an entirely new outlook and philosophy of life. Everywhere in the teeth of every sort of ignorance, prejudice and vested interest, academic, political and financial, I have witnessed the realization spread over the world like wildfire, since the Great War, of what the scientific civilization might be, but for the procrustean bed of a private, upstart and frustrating monetary system.

Academic scientists, I should judge, have much more to learn of the potentialities of an unfrustrated and deprocrusticated scientific civilization than they are able to teach. They seem still pitiful dupes of Procrustes, at best trying to mitigate the sufferings of those mutilated, rather than to provide a decent bed, and only now really interested because their own precious freedom from interference is being threatened.

The proposal is for a new sort of Royal Society to be formed to discuss these matters, having a large membership and all the usual paraphernalia of council, committees, "suitable" referees, regular meetings, symposia and publications. Though it has to deal with subjects which, not to put a gloss on it, affect everybody's pocket more or less and that of Procrustes very closely indeed, its attitude is to be strictly objective and scientific. It is not to express corporate "opinions" (decisions or conclusions, surely, would be less 'in the dreary and barren dialectical tradition') but everyone is to be left free to make up his own mind as an individual. It is claimed that what has worked well in the old field of knowledge for its own sake will, there is every reason to believe, meet with "like success" in the new. Accepting, so to say, the prospectus at the promoters' own valuation, "like success" means nothing beyond the creation and diffusion of a well-informed body of opinion. What is proposed is just another debating society in addition to the hundreds of societies studying this very problem all over the world, but distinguished by being composed preponderatingly of people to whom both the technique and methods of science are familiar, qualities which are rather more in evidence in the individuals engaged in the pioneering of new knowledge than in their organizations.

Well, the existing societies already studying these problems in much this way without, it is true, the qualification of mass scientific intellect, have come to a sort of consensus of opinion that it is the monetary system which is at the bottom of the whole hell's brew. Is the proposed society to be allowed to make a purely scientific and objective investigation into the existing money system ? The lack of specific reference to this in the agenda, and, indeed, the rather naïve idea underlying this new phase of the movement, that the massive intelligence of organized science should be shipped off on a quest into these uncharted seas, when as a matter of fact the whole thing already could be made clear to the uncorrupted mind of a child, makes me ask the question. If I may suggest the answer, it is that in a matter so nearly touching the very core of government, the new society like the old will be expected to be on the side of the Government of the day, whatever that may be, rather than on that of the veiled goddess.

Be that as it may, I am sure everyone who has already been independently examining the question with an open mind will want to know on which side of the fence the proposed society is expected to sit; whether, like the Royal Society in so far as, since the War, it has largely become an unofficial part of the Civil Service, it is to be concerned with the sort of knowledge most useful in preserving and strengthening the existing framework of society, or with changing that framework so as to make the world safe for a scientific civilization. I know that, theoretically, the two sides should be the same, but in practice they may be exact opposites.

When we come to what after all is the object, *the change of the system*, be it the monetary system or whatever else may be adjudged to be the prime cause of civilization running off the rails, what is the use of a debating society ? Are we still supposed to subscribe to the idea that "in this country at least", once a sufficient and sufficiently well-informed body of opinion exists as to what is wrong, it will come all right ? I suppose some people still think vaguely along these lines, but I am not among them, not in the present instance.

If we study actual examples of changes recently effected, associated with the names of Mussolini, Gandhi, Hitler, Lenin and his successors, much as they differ in method, they all seem to depend primarily on the creation or renewal of faith in the future destiny of their own particular race or civilization. So it would appear that, if the scientific civilization is to survive, scientific workers should strive to create a mass-belief in its superiority, as regards both material and spiritual satisfactions, alike over the hoary civilizations we are still imitating, and the meteoric substitutes since the War. All scientific thinkers must themselves feel this superiority intensely, but it would be a good thing if their allegiance was less clannish, and, in their external relations, they were less like the herd in thinking these threatened catastrophes as either inevitable or beyond the power of science to prevent. For, indeed, the amount of science required is, in my view, much of the two-plus-two variety. What is more wanted is not a new organization but a Crusade of Scientific Civilizers, a C.S.C. not an S.R.S.

Frederick Soddy.

Complex Formation in Lipoid Films

It was shown recently[1] that when extremely dilute solutions of certain substances were injected into the substrate under monolayers of various types, the injected substance (for example, cetyl sulphate) penetrated the monolayer (for example, cholesterol), forming a mixed film containing equal numbers of the two molecular species. These experiments were carried out at constant area.

Two experimental methods have now been devised to study area changes in these mixed films formed by the penetrative process under various compressions. In one, a Langmuir trough is employed, the surface tension of the solution behind the barrier being separately determined. In the other, a thin strip of waxed paper attached to the sides of the trough by long vaselined silk threads serves as a barrier. The monolayer under examination is placed in front of the barrier, and behind it a lens and film of a suitable substance serves as a Langmuir piston to compress the monolayer. This piston film, for example, triolein (piston pressure 23 dynes/cm.), must consist of a substance which is not penetrated by the material injected into the substrate.

With a monolayer of cholesterol compressed by a triolein piston, the injection of a dilute solution of digitonin causes an immediate expansion of the monolayer to twice the area, and the previously liquid cholesterol film becomes solid. The triolein is unimpaired and continues to exert a compressive pressure of 23 dynes per cm. If instead of digitonin, cetyl sulphate in suitable concentration be injected and oleic acid is employed as piston (35 dynes/cm.) the area increase is only 50 per cent instead of 100 per cent. Here again, since the molecular areas of cholesterol, digitonin and cetyl sulphate are 40 A.^{2}, 40 A.^{2} and 20 A.^{2} respectively, a complex of 1 : 1 is formed. Replacing oleic acid by the less compressive triolein piston, it is found that on injection of the cetyl sulphate there is an immediate expansion of 50 per cent forming the 1 : 1 complex. This is followed at these lower pressures by a further slow expansion, indicating the formation of a less stable complex of the composition cholesterol, cetyl sulphate (1 : 2). Care has to be taken to avoid leaks, since the detergents in excess remove the liquid paraffins from the threads.

It is of interest to note that a solution of cholesterol in petrol ether spreads rapidly on water and on a solution of cetyl sulphate, but not on digitonin; hence surface peptization is only brought about by the formation of complexes which must be liquid and in order to spread must have stability pressures greater than the equilibrium surface pressure of the underlying solution. With the Langmuir trough it is possible to examine this complex formation over a wider range of areas and pressures. The following general types of complex emerge from this investigation.

(*a*) When both monolayer and penetrating molecules are ring structures, only 1 : 1 complexes are stable.

(*b*) i. When the penetrating molecules are chains penetrating into a monolayer of ring structure, complexes containing one, two, and possibly three chain molecules per molecule in the monolayer have been established.

(*b*) ii. In the inverse system to the above, two chain molecules in a monolayer can interlink with one ring structure molecule from the substrate.

(*b*) iii. Finally, if both monolayer and substrate molecules are linear, two, and possibly as many as three, molecules from the substrate can form from a complex with one in the monolayer, in agreement with a centred hexagonal packing.

(*b*) iv. Van der Waals forces play a large part in the stability of these complexes; thus if dodecyl sulphate instead of cetyl sulphate be used, only very weak 1 : 1 complexes can be established.

We may note that in chain-like molecules insertion of a double bond in the chain may reduce the penetrative power; thus cetyl sulphate penetrates readily a film of the *trans* elaidyl alcohol to form an 'interlocking' solid, 1 : 1 mixed film, but only penetrates with difficulty the *cis* oleyl alcohol, to form a liquid film readily decomposed by pressure. As is to be anticipated, the formation and stability pressures of a series of complexes is dependent not only on the surface pressure, but also on the bulk concentration of the penetrating agent. Again, the formation of complexes is in many cases extremely sensitive to quite minor changes in the *p*H of the underlying solution; thus bilirubin penetrates cholesterol with ease at *p*H 7·2 but has a negligible effect at *p*H 8·2. Biliverdin does not penetrate cholesterol at all. On the other hand, taurocholic acid forms no complexes with bilirubin as measured by these methods.

It is hoped shortly to give an account of the systems investigated, together with the data on the stability of complexes of cholesterol with various substances in respect to their hæmolytic activity and with natural pigments and bile salts as a possible factor in the formation of gall stones.

Isomeric Forms of Radio Rhodium

When bombarded by neutrons, rhodium gives two radioactive periods, 44 sec. (Rh_1) and 4·2 min. (Rh_2), both being associated with the emission of negative electrons.

Amaldi, Fermi[1], and Segrè[2] have shown that the ratio of the two activities produced in rhodium by *slow* neutrons does not change if the neutrons are filtered with cadmium or rhodium. This indicates that the resonance levels for the capture of slow neutrons which lead to the formation of Rh_1 and Rh_2 have about the same energy and breadth. This supports the hypothesis that the formation of Rh_1 and Rh_2 corresponds with the capture of neutrons in a single level of a definite isotope, that is, that Rh_1 and Rh_2 are two isomeric forms of the same isotope. The experiments of Frisch, von Halban and Koch[3] lead to the same conclusion. A possible explanation of nuclear isomerism has been proposed by Weizsäcker[4].

It is interesting to examine the significance of the ratio R of the saturation intensities of the two periods (all references will be to the 'true ratio', account being taken of the penetration of β-rays and neutrons; the details of the following experiments will be published elsewhere). When a neutron is captured, the compound excited nucleus may emit one or more photons before falling either to the state corresponding to Rh_1 or to that corresponding to Rh_2. The experimental ratio R will give the ratio of the probabilities of formation of Rh_1 and of Rh_2 from a capture level.

One may ask whether this ratio varies when the capture level changes, that is, when one varies the energy of the incident neutrons. There is evidently a close analogy between this question and the following: Does a change in neutron energy vary the spectral composition of the γ-radiation which is emitted by a nucleus in the capture of neutrons? An experiment on the capture radiation of slow neutrons in gold[5] has answered this question in the affirmative. Considering the experimental difficulty in studying γ-radiation in this case, it is easier to follow the same general investigation by means of new methods such as those described in the following. The rhodium (Dr. Jacquet kindly made an electrolytic deposit of 5 mgm./cm.^{2}) on the interior of a nickel cylinder was irradiated for 20 minutes and its activity was followed in a Geiger-Muller counter with a thin aluminium wall (the counting began 20 seconds after the end of the irradiation).

From the curve of decay of the total activity ($Rh_1 + Rh_2$) one can deduce the value of the ratio R of the initial intensities of Rh_1 and Rh_2. This ratio was determined:

(*a*) With a source of radon plus beryllium (or radio-actinium plus beryllium) in the presence of paraffin. In this case it is known that the ratio R does not depend upon geometric conditions[1]. The result $R_a = 11 \pm 0{\cdot}7$ confirms the value found by Segrè[2].

(*b*) With a source of radon plus beryllium placed on the axis of the cylinder of rhodium, in the absence of paraffin and all hydrogenous media. It is known that for a radon plus beryllium source the number of neutrons of energy greater than 10^5 e.v. is probably less than 10 per cent of the total number of neutrons emitted[6]. Moreover, as the capture cross-section in general is greater the slower the neutrons, one can say that the rhodium cylinder is bombarded by heterogeneous neutrons with a mean energy less than 10^5 e.v. The irradiation was made at the interior of a 'castle' of lead, thus augmenting the activity through the presence of neutrons diffused by inelastic collisions in the lead. The mean energy of these neutrons is smaller than that of the slow group of neutrons from radon plus beryllium, as one can determine by measuring directly the absorption in cadmium[7]. The value $R_b = 6 \pm 0{\cdot}5$ was obtained.

It should be noticed that in (*a*) the experimental value R_a is relative to the neutron capture by a *single level*. On the other hand, in (*b*), R_b represents a *mean value* referring to a great number of levels. This is due to the fact that the neutrons which excite Rh_1 and Rh_2 in the conditions (*b*) have a very complex spectrum. Moreover, in the case (*b*) the breadth of the levels is probably greater in the mean than is their separation. It might be expected that in an energy interval which is small with respect to the total excitation energy of the nucleus, the *mean value* of R should not change appreciably. Consequently, the result of this experiment ($R_a \pm R_b$) seems to show that the mean value of R in a certain energy interval differs from the value relative to a single level of this interval.

This is in accord with the experiment on the γ-radiation of capture in gold and with the experiments on the selective production of isomeres in uranium[8], that is, neighbouring levels show a difference of behaviour (in the sense already explained).

As Placzek has remarked[9], it seems that the nuclear levels can be grouped into different classes which cannot intercombine in the spectroscopic sense of the word.

After these experiments were finished, there was published the results of measurements of R in rhodium for neutrons of different energies[10]. Here, however, it is difficult to draw conclusions on the radiative properties of the nucleus, because the value of R was determined in one case for slow neutrons and in the other for neutrons of very high energy (neutrons from D + D : 2·4 M e.v.).

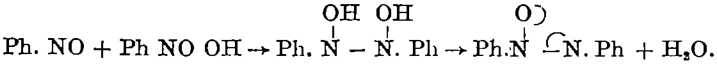
Formation of Mesomeric Systems

THE recent article[1] by Prof. Ingold on "Resonance and Mesomerism" prompts me to refer to an aspect of this subject which has presented itself in connexion with the study of aliphatic diazo-compounds[2].

The tendency to the formation of saturated systems (for example, of aromatic from dihydrobenzene or from quinonoid derivatives; and of conjugated from unconjugated dienes) is a commonplace of organic chemistry. The generalization, that mesomeric systems are likely readily to be formed from others closely related to them, not only embraces those just mentioned but is also much wider in scope and should prove to be correspondingly more valuable. Thus, adopting Ingold's notation, we at once comprehend the formation of azoxybenzene (I), or of diazoamino- (II) in preference to aminazo-compounds:



$$Ph.NO + Ph\,NO\,OH \rightarrow Ph.\overset{OH}{\overset{|}{N}} - \overset{OH}{\overset{|}{N}}.Ph \rightarrow Ph.\overset{O}{\overset{\uparrow}{N}} - N.Ph + H_2O.$$

(I)

$$PhN_2Cl + R\,NH.Ph \rightarrow Ph\,N - N - NR.Ph.$$

(II)

The transition from methyl diazohydroxide to diazomethane is exactly comparable with these :

$$CH_3.N = N.OH \rightarrow H_2\overset{\frown}{C-}N\overset{\frown}{-N} + H_2O.$$

Similarly, whilst ammonia and aliphatic amines merely form additive compounds with aldehydes, loss of water ensues when aromatic amines, hydroxylamine, etc., are employed, so that mesomeric systems

$$>\overset{\frown}{C-}N\overset{\frown}{-Ph},\quad >\overset{\frown}{C-}N\overset{\frown}{-OH}, \text{ etc.}$$

may be generated.

Their mesomeric character must also conduce to the generation of such systems by synthesis, and this is exemplified by the facile oxidation of nitrosobenzene, hydrazobenzene, azobenzene, isocyanides and *iso*acetylenes respectively to nitrobenzene, azobenzene, azoxybenzene, isocyanates, and ketenes. The formation of unsaturated systems is a special and particularly important case of this kind. The easy generation of styrene from boiling α-phenylethyl bromide, of stilbene from dibenzyl, of phenylbutadienes from the corresponding cinnamyl methyl carbinols, and of ethyl styrene by reduction of phenylbutadiene, are examples of long standing in the literature. Contemporary instances are readily discerned in the various syntheses of polyenes evolved by R. Kuhn and his collaborators[3], not the least noteworthy and significant being the adaptation of Klinger's synthesis of stilbene by reduction of thiobenzaldehyde. Similarly, it may well be that resonance is a determining factor in the biosynthesis of carotinoid and similar substances.

It would also appear that among inorganic compounds the familiar tendency of compounds representing intermediate stages of oxidation to pass spontaneously into others of lower and higher degrees, respectively; for example

$$3ClO' \rightarrow 2Cl' + ClO'_3,$$

is attributable to the greater resonance in the latter, as is also Luther's well-known rule, that in the conditions under which the transition occurs the intermediate stage of oxidation corresponds to a greater oxidation potential than the higher one. Similar considerations may explain the tendency of non-resonant anions derived from a single atom, for example, sulphur, halogen, or oxygen, to form resonant complexes by combination with elementary sulphur, free halogen, and atmospheric oxygen respectively. From this point of view, it might be anticipated that the ionic rather than the homopolar condition would be the predisposing factor, and it is noteworthy that, among the alkali and alkaline earth metals, it is the oxides of the most electropositive which most readily form higher oxides.

Deuteron-induced Radioactivity in Oxygen

WHEN oxygen gas and several oxides (carbon dioxide, tungsten trioxide and water) were bombarded by 2 M.e.v. deuterons, which were obtained by the aid of our cyclotron, two periods for oxygen were definitely established.

A first period of one minute and a half is identified with that of ^{17}F, which has been already established by many authors[1,2].

A second period of 120 min. is shown by chemical separation to be also due to an isotope of fluorine and is close to the 112 min. period of ^{18}F found by Snell[2], when he bombarded neon with 5 M.e.v. deuterons, and also to the 107 min. period of the same isotope found by DuBridge, Barnes and Buck[3], when they bombarded oxygen with high-speed protons (1·4–3·8 M.e.v.). We thus identify the second isotope with ^{18}F.

The energy histogram of positrons emitted from this isotope was taken by the aid of a Wilson cloud chamber filled with hydrogen. The upper limit of the energy is found to be $0{\cdot}7 \pm 0{\cdot}05$ M.e.v. This is again close to 0·6 M.e.v.[3] and 0·5 M.e.v.[2], which were obtained from absorption experiments.

This isotope may possibly be produced according to the reaction :

$$^{17}O + {}^{2}H \rightarrow {}^{18}F + {}^{1}n$$
$$^{18}F \rightarrow {}^{18}O + e^{+}$$

The relative abundance of this isotope of oxygen is very small; hence to get an appreciable quantity of ^{18}F the cross-section of this reaction must be rather large. Further, when we consider the large abundance of the oxygen isotope ^{16}O, there remains a certain probability that it may be attributed to the following reaction, which has not yet been observed.

$$^{16}O + {}^{2}H \rightarrow {}^{18}F + h.$$

If this is the case, γ-rays of about 11 M.e.v. would be expected to be emitted during this reaction, according to mass defect consideration.

As for the third isotope of oxygen, ^{18}O, the reaction :

$$^{18}O + {}^{2}H \rightarrow {}^{18}F + 2{}^{1}n$$

must be abandoned according to the energy relation unless the kinetic energy of the deuteron exceeds 5 M.e.v.

The full account of the energy histogram and the Konopinski-Uhlenbeck plot of positrons emitted from ^{18}F will shortly be published, together with those of ^{13}N, in the *Scientific Papers* of this Institute. In conclusion, our thanks are due to Dr. Y. Nishina and other members of this Laboratory for their continuous interest and valuable assistance. We wish to thank the Japan Wireless Telegraph Company for the electromagnet and other equipment used for the cyclotron, and the Mitsui Ho-onkwai Foundation and Tokyo Electric Light Company for financial support.

Sodium in the High Atmosphere

In the spectrum of the sky at twilight, a yellow radiation was found very near the mean wave-length of the sodium D lines ($\lambda = 5893$ A.). This radiation is relatively strong, but its intensity decreases abruptly in one or two minutes (Fig. 1), as if it was first excited, or rather considerably enhanced, under the action of the sunlight. Observations made at the Tromsø Observatory, in the autumn of 1937, have shown that the excitation occurs in a layer at the altitude of about 60 km.

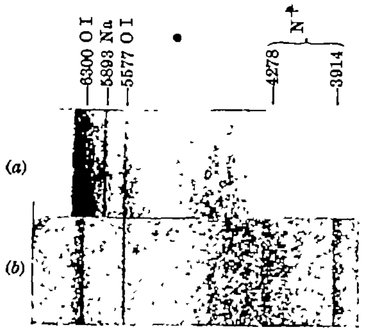

FIG. 1.

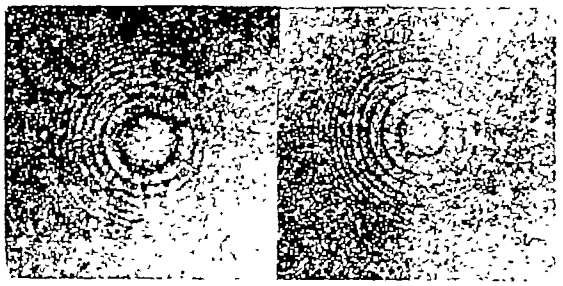
TWILIGHT SPECTRA (TROMSØ). (*a*) EXPOSURE, 15h. 47m.–15h. 52m. (*b*) EXPOSURE, 15h. 53m.–15h. 58m.

The same phenomenon was observed in December 1937 at Saint-Auban (Basses Alpes, France) and later in Lyons. In these latitudes, the shorter duration of twilight does not permit the determination with the same precision of the moment at which the yellow radiation practically fades. However, from a few spectrograms obtained in France, the altitude of the upper limit of the luminescent layer has been found again to be nearly equal to 60 km., in perfect agreement with the Tromsø measurements.

The yellow radiation was also studied by the interference method, using Fabry and Pérot interferometers (having glass plates 0·15 or 0·30 mm. apart) and also a quartz plate 1·5 mm. thick approximately. The results proved that this radiation really consists of the two D lines. In Fig. 2 are shown magnified reproductions of the rings from the twilight radiation, isolated by using special plates (sensitivity rapidly decreasing from the yellow to the red) and a suitable filter limiting the spectrum at 5750 A. On the left half of each picture, the rings produced by the yellow light of sodium (alcohol flame with sodium chloride) have been superposed on those of the twilight radiation. The coincidence is absolute and remains so, whatever the interferometer used.



(*a*) (*b*)

FIG. 2.

INTERFERENCE PICTURES OF THE TWILIGHT YELLOW RADIATION. (*a*) 0·15 mm. ÉTALON (D_1 AND D_2 DISTINCT); (*b*) 0·30 mm. ÉTALON (D_1 AND D_2 SUPERPOSED).

The D lines might be expected also in the night sky spectrum, on account of the presence of a yellow radiation having the proper wave-length (Slipher, Dufay, Cabannes). Their intensity would be only enhanced during twilight, probably by resonance excitation. In order to ascertain that this is so, the yellow radiation of the night sky has been studied (exposure: 11 hours, night almost without any moonlight), with one of the devices previously used for the twilight radiation. Rings perfectly clear, although less contrasted, have also been photographed under these conditions (Fig. 3). They are absolutely identical with those from the twilight doublet. In the two cases, the ratio of the intensities of the components D_2 and D_1 seems to have the normal value 2 : 1.

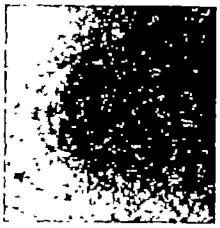


FIG. 3.

INTERFERENCE PICTURE OF THE NIGHT SKY YELLOW RADIATION (0·15 mm. ÉTALON).

These observations bring out the first decisive proof of the existence, in the high atmosphere, of an element distinct from the normal constituents of the air.

Adsorption Potentials at Polar Liquid-Liquid Interfaces

A GREAT deal of work has been done by Hober, Cremer and many other investigators on the so-called 'oil-potential', that is, the potential difference (P.D.) between two aqueous solutions, separated by some water-insoluble organic fluid. The latter is for abbreviation called the 'oil'. The simplest type of such a cell is the following, a 'concentration cell':

Electrolyte, c_1, in water/'oil'/same electrolyte, c_2, in water. $c_1 > c_2$.

It has been generally assumed that the electrolyte involved diffuses very rapidly from the water into the oil so that the P.D.'s observed refer to a state of *partition equilibrium* of electrolyte immediately at the phase boundaries and of stationary diffusion inside the oil. From these assumptions the following formula has been derived for a (1–1) electrolyte:

$$\text{P.D.} = V = \frac{U_- - U_+}{U_- + U_+} \cdot \frac{RT}{F} \ln \frac{c_1}{c_2}$$

where U_- and U_+ are the mobilities of the ions in oil. However, the P.D.'s actually reported at different c_1 and c_2 often show a very poor agreement with any logarithmic formula. A great number of measurements have forced us to the conclusion that this classical theory is not consistent. In fact, we have been led to a different view.

We suggest that a great many of the 'oil potential' measurements, recorded in the literature, do not refer to a true partition equilibrium of the electrolyte on both sides of the interfaces, but only to an *ion adsorption equilibrium* between the aqueous phases and the interfacial layer. This should always be the case, when inorganic electrolytes are used and no special care has been taken to attain partition equilibrium, for example, by prolonged shaking of the phases. If, on the other hand, partition equilibrium is secured, P.D.'s are obtained different from the ion adsorption equilibrium P.D.'s and not so easily reproducible as these. The stability, the reproducibility and reversibility of the ion adsorption equilibrium P.D.'s within a few millivolts seem to indicate that the partition equilibrium of the electrolyte is not achieved even after a considerable time, even in the outer oil layers.

The interface oil/water can safely be assumed to consist of a single layer of 'oil' dipoles, the hydrophilic end groups pointing waterwards. If these are *negatively* charged (for example, CN, CHO, OH, NO_2, Cl), they should attract a monomolecular layer of positive ions, which are in turn coated by a diffuse cloud of negative ions. In a 'concentration cell' containing such an oil between dilute solutions of an electrolyte, the more concentrated solution should be the negative pole (as for the reversion of the effect at high electrolyte concentrations, see below). The P.D. should, moreover, be more dependent on the individual properties of different cations than those of the different anions. If an oil with *positive* hydrophilic end groups (for example, NH_2) is used, the conditions are reversed: concentrated electrolyte solutions are positive against dilute ones, and specific anion properties are prominent. These facts were discovered by Beutner and explained by him from a classical point of view as due to the 'acid' or 'alkaline' nature of the oils, but also non-acid oils like $ArNO_2$ and ArCl ($Ar=C_6H_5$) behave like Beutner's 'acid' oils.

We have derived the following approximate expression for the P.D. of each interface *c–n* (1–1) electrolyte in water/oil, the total P.D. being the difference of two such expressions:

$$V = V_0 + \Theta V^1 + \frac{2RT}{F}\sinh^{-1}\Theta\sqrt{\frac{K}{c}}\,;\ \Theta = \frac{c}{c+c_0}\,;$$

where R, T, and F have their ordinary meanings, V_0 is a characteristic of the oil and V^1, K, and c_0 are constants of both the electrolyte and the oil; c is the electrolyte concentration in water and Θ the fraction of the interface covered with ions. The second formula is simply the Langmuir adsorption isotherm.

Our experiments are in good agreement with the predictions of this formula. When the concentration c is raised, $\partial V/\partial \ln c$ (which should be a constant according to the classical theory) first rises to a maximum, then decreases and in several cases even passes through zero and changes its sign, as, for example, for acetophenone with potassium chloride in water at $c=0{\cdot}02$.

Methylene blue chloride, which is very insoluble in $ArNO_2$ and ArCl, will, if added to one side of a cell with one of these oils, give large negative P.D.'s amounting to more than 200 mv. The V ($\log_e c$) curve is certainly not linear and for $ArNO_2$ it is in one part more than twice as steep as would be possible by any classical formula. However, the P.D.'s are well described by the above formula and agree fairly well with the Θ's calculated from the figures of Gibby and Addison[1]. From the classical point of view it is quite inexplicable that, for example, $(C_2H_5)_2NH.HCl$, which is certainly about 10^4 times more soluble than methylene blue chloride in these oils, will give P.D.'s smaller by several orders of magnitude.

The addition of a non-electrolyte to one side of a symmetrical oil cell will often produce a high P.D. If $ArNO_2$ is used, dilute solutions of iodine and mercuric cyanide give positive potentials, di-ethyl sulphone, acetaldehyde, methyl cyanide and others give negative potentials, varying between 30 and 200 mv. This we ascribe to a change in the electrical moment of the interface by adsorption of non-polar or di-polar molecules.

The ion adsorption equilibrium P.D.'s may play a part in physiology, for example, in the mechanism of the olfactory and gustatory systems and the activity of local anesthetics, and may therefore be well worth studying. In contrast to the partition equilibrium P.D.'s they are distinguished by good and rapid reversibility. They are, moreover, sensitive to very small amounts of certain substances (even in concentrations of 10^{-7} mol.).

A full report of our investigations, which are proceeding, with additional support for our views, will be published elsewhere.

Amino-derivatives of Pentaerythritol

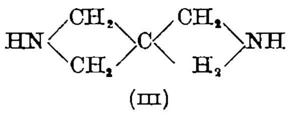
TETRAMINO-TETRAMETHYL-METHANE, $C(CH_2NH_2)_4$, was first prepared (in the form of its salts) by Govaert[1] by heating tetrabromo-pentaerythritol, $C(CH_2Br)_4$, with alcoholic ammonia in sealed tubes. This preparation has recently been repeated by van Alphen[2], who has isolated the free base and prepared various derivatives. The method of preparation is unsatisfactory, however, as the quantities of the tetrabromo-compound employed are limited by the use of sealed tubes, and the yield is low.

We have been investigating the amino-derivatives of pentaerythritol and their synthetic uses for some time, and have worked out a method for the speedy preparation of the tetramine in quantity.

When tetrabromo-pentaerythritol is heated with sodium *p*-toluene sulphonamide, $C_7H_7SO_2NHNa$, the tetrasulphonamido-compound (I), of m.p. 248°, is obtained in good yield, and on treatment with sulphuric acid is readily hydrolysed to the required tetramine. The latter can be isolated as the disulphate (II), which is almost insoluble in water.

$C(CH_2NHSO_2C_7H_7)_4$ (I)

$C(CH_2NH_2)_4,2H_2SO_4$ (II)

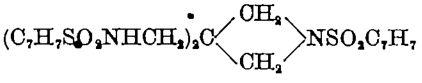


(III)

Govaert states that when aqueous solutions of the tetrahydrochloride of this amine are evaporated, ammonium chloride is broken off with the formation of the dihydrochloride of the spirocyclic diamine (III). We find, however, that the tetrahydrochloride can be recovered unchanged after it has been submitted to the following processes: (*a*) evaporated with water for 36 hours, (*b*) boiled with hydrochloric acid under reflux for 20 hours, (*c*) heated with hydrochloric acid in a sealed tube at 160° for 5 hours.

Methylation of the tetramine readily yields the octa-methyl compound, $C(CH_2N(CH_3)_2)_4$, which even with an excess of methyl iodide gives the bi-quaternary iodide $C(CH_2N(CH_3)_2)_2(CH_2N(CH_3)_3I)_2$: our attempts to prepare the quadri-quaternary iodide, $C(CH_2N(CH_3)_3I)_4$ have not at present succeeded.

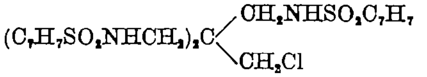
The preparation of the tetrasulphonamide (I) gives a small quantity of a trisulphonamide, $C_{26}H_{31}N_3O_6S_3$, of m.p. 214°, as a by-product. This compound has apparently the 4-membered ring structure (IV): hydrolysis with sulphuric acid opens the ring and gives the monohydroxy-triamine (V). Hydrochloric acid also opens the ring giving the chloro-compound (VI), which on complete hydrolysis followed by steam distillation undergoes ring closure again to give the monocyclic triamine (VII).



(IV)

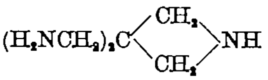
$C(CH_2OH)(CH_2NH_2)_3$

(V)



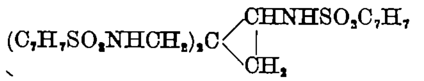
$$(C_7H_7SO_2NHCH_2)_2C\begin{matrix} \diagup CH_2NHSO_2C_7H_7 \\ \diagdown CH_2Cl \end{matrix}$$

(VI)

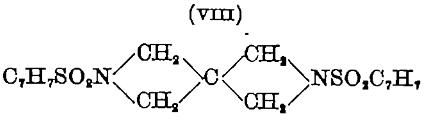


(VII)

Monoacetyl-tribromo-pentaerythritol, $C(CH_2Br)_3(CH_2OCOCH_3)$, when heated with sodium *p*-toluene sulphonamide, gives two derivatives. The first is a trisulphonamide, of m.p. 171°, isomeric with (IV), and having apparently the *cyclo*-propane structure (VIII): the second is the spirocyclic disulphonamide (IX), of m.p. 185°. Both (VIII) and (IX) on hydrolysis with hydrochloric acid followed by steam distillation give the spirocyclic diamine (III). The constitution which we have provisionally allotted to the isomeric compounds (IV) and (VIII) is supported by the fact that their sodium derivatives on treatment with benzyl bromide give a dibenzyl and a tribenzyl derivative respectively.



(VIII)



(IX)

The tetramine $C(CH_2NH_2)_4$ is now being used to investigate the stereochemistry of its spirocyclic organic and complex metallic derivatives.

Purified Uricase

In the attempt to isolate the enzyme uricase from pig liver, I have obtained a preparation 550 times purer than the enzyme powder used as starting material. The purified preparation contains 0·15–0·18 per cent Fe, 14·4 per cent N, traces of copper, and no cobalt or manganese. It is almost colourless, and therefore is not a hæmin derivative. It is insoluble in water, almost insoluble in phosphate buffer *p*H 7·4, and soluble in borate buffer *p*H 10. Truszkowski[1] has already shown that uricase is soluble in alkaline solution.

The highest specific activity obtained, as measured by the oxygen uptake during the oxidation of uric acid in manometers, is 85 c. mm. per mgm. enzyme per minute as compared with a value of 0·15 c. mm. per mgm. per minute for the powder used as starting material. The test is arranged as follows: The main chamber of the manometer vessel contains 1·0 c.c. *M*/5 borate buffer *p*H 9 and 1·5 c.c. enzyme preparation plus water. The potash tube contains 0·2 c.c. 10 per cent caustic potash, and the side bulb 2·24 mgm. uric acid (as *M*/30 lithium urate). The gas space contains pure oxygen and the oxygen uptake is measured at 38° over a period of 30 minutes.

If it is assumed that the catalytic activity of the enzyme is due to the iron (although this has not yet been proved), then 1 mgm. iron brings about the reaction of 57,000 c. mm. oxygen per minute.

Lactoflavin in the Eyes of Fish

Some years ago we found[1,2,3] that the retinal pigment epithelium of the eyes of a number of fish contained relatively large amounts of flavin. Liver and kidney, which are known to be the materials richest in flavin, contain about 20 γ flavin per gm. tissue, while an approximate calculation of our results indicated in the pigment epithelium of some fish eyes 500 γ flavin per gm. tissue.

Flavin occurs in tissues almost entirely combined with protein as an enzyme which does not show the characteristic fluorescence of flavin and is not dissociated at neutral reaction. It was, therefore, a surprising observation that flavin of the pigment epithelium showed green fluorescence in water extract and was almost completely dialysable[2,3]. When the eye of a freshly killed fish was frozen in acetone - carbon dioxide mixture and cut by a meridional section the flavin contained by the pigment layer could be directly observed in the fluorescence microscope[4]. The spectrum of the green fluorescence light was identical with that of the flavin. The flavin from haddock eyes was also isolated and identified by Karrer[5] as lactoflavin. From these observations we concluded that flavin in the eye occurred in the free state or in the form of a highly dissociated protein compound but not as flavin enzyme. Thus the eye is the only tissue known which contains flavin mostly or entirely in the free form. Otherwise free flavin occurs only in milk and urine[6].

There was one detail of the problem not clear yet, namely, the question whether flavin in the fish eye originally occurs in the form of lactoflavin or as its phosphoric ester. The latter compound would show the same fluorescence as flavin itself, but during the isolation process it might have lost the phosphoric acid group.

Recently Emmerie[7] has shown that flavin can be easily separated from flavin phosphoric acid by means of certain solvents. Benzyl alcohol, for example, dissolves flavin[8] but not the flavin phosphoric ester.

The application of this simple principle to the present problem showed us soon that the flavin of fish eyes was free flavin and not flavin phosphate. The eye of a big cod was detached immediately after killing, frozen in solid carbon dioxide, and the separated retina and pigment layer were extracted by grinding with ice water. By shaking the sharply centrifuged yellow solution with benzylalcohol three times the flavin was completely extracted. When lactoflavin phosphoric acid* was added to the water extract of the pigment layer of another eye it remained in the water phase after a similar treatment with benzyl alcohol.

The occurrence of free flavin in the eye suggests that flavin phosphate taken up with the food is dephosphorylated for its deposition in the eye. According to Kuhn[9], free flavin may also form an active compound with the protein part of flavin enzyme. This compound, contrary to the flavin enzyme, which is a flavin phosphate protein compound[10], is highly dissociated into its inactive components. The occurrence of free flavin suggests, therefore, that its function in the eye may be not that of a redox catalyst but that it may take part in the visual processes by means of its photochemical properties[11,12], as fluorescence and light sensitivity.

Spore Formation in a *Vibrio*

WHILST nitrate reduction is a property common to a large group of bacteria belonging to very divergent genera (*Micrococcus, Pseudomonas, Bacillus*, etc.), all investigators who have thoroughly studied the important natural process of sulphate reduction agree that the causal organism is in all cases the strictly anaerobic typically vibrio-shaped bacterium first described by Beijerinck in 1895[1]. It is true that the strains isolated sometimes show slight mutual differences which have led to the creation of one or two separate species or varieties, but this circumstance does not detract from the remarkable fact that these strictly anaerobic representatives of a genus which until now has generally been considered to be non-spore-forming (apart from a few quite equivocal cases in the older literature) are almost universally distributed in Nature.

Seen in this light, it seems worth reporting that during investigations carried out in the last six months, decisive proof has been obtained that spore formation occurs in *Vibrio desulfuricans*. This fact has first been ascertained for pure cultures of the thermophilic variety earlier described by Elion and by Baars. It was then found that soil, canal and ditch mud, and sewage after having been heated for 30 minutes in boiling water, readily yielded active cultures of sulphate-reducing vibrios, when inoculated into the usual lactate enrichment medium both at 55° C. and at 30° C. In these cultures various morphological variations occur leading ultimately to the formation of spindle-shaped or slightly bent cells with sub-terminal, highly refractive spores about $1{\cdot}7 \times 1{\cdot}3\mu$ in size. Subcultures could be obtained by transferring these original cultures after they had been heated in boiling water for an hour. Cells in these cultures were the typical actively motile vibrios and spirals. Pure cultures obtained by repeated plating continue to produce spores when grown in various media in the temperature region between 45°–55° C. However, continued cultivation in the lactate medium at temperatures below 40° C. makes the cultures rapidly asporogenous, and this circumstance may well be responsible for the fact that spore formation in this species has been entirely overlooked until now, even by such a highly competent bacteriologist as Beijerinck.

The new generic name *Sporovibrio* is proposed for the sporulating, anaerobic, Gram-negative, curved bacteria of this type.

The circumstance that under certain conditions cultures of *Vibrio desulfuricans* show a perfect and very regular spirillum-shape—hence the name of *Spirillum desulfuricans* as originally proposed by Beijerinck—makes it seem worth while to carry out renewed investigations regarding the spore-forming ability of other representatives of both the genera *Spirillum* and *Vibrio* (*Vibrio choleræ* !).

Ounce Molecular Weight of a Gas

IT does not appear to be generally recognized that an 'ounce molecular weight' of a gas will fill 22·4 cubic feet under a pressure of one atmosphere and at 0° C. This relationship is very useful as a starting point in many calculations of gas quantities in English units, and it might well be inserted in text-books of physics and chemistry at the same time as the more conventional statement involving gram-molecular and litre units is presented.

The existence of this relation must have been noted by various workers, but it has undoubtedly not received the prominence and general use which it deserves. Since noting it myself independently in 1920, I have always found that its existence and use have been regarded as surprising and novel by any to whom I have mentioned it, until recently when I have been informed that the relation has in fact received text-book publication and indeed appears in the form of a problem set on p. 999 of Partington's "Textbook of Inorganic Chemistry".

It is additionally interesting to observe that the volume of an 'ounce molecular weight' of gas under N.T.P. conditions may conveniently be visualized, within an accuracy of one half per cent, as the volume of a carpet of gas 15 feet square and one tenth of a foot thick: the weight of this quantity of oxygen is two pounds.

Salaries in Soviet Universities

IN estimating the income and standard of life of Russian professors, Dr. L. H. Callendar, in NATURE of February 12, has been influenced by the two misconceptions most frequently held by foreign visitors to the U.S.S.R. One is an undue pessimism in gauging the true value of the rouble, due to the fact that a foreigner always comes up against the most expensive items in the Soviet citizen's budget; and the other is the fact that if a professor earns 1,200 roubles a month, his wife will most certainly be earning at least half that sum. As I have just returned from more than five years' residence in the U.S.S.R., I can guarantee the authenticity of the following figures, which enable a comparison to be made of the standards of life in the two countries. The distribution of items is, of course, more or less arbitrary.

The average income of a Soviet professor is greater than Dr. Callendar states. Those whom I knew were all earning at least 1,500 roubles a month, but I shall assume an income of 1,200 roubles and a wife's income of 600 roubles, and shall compare the expenditure of a Russian family, consisting of husband, wife and two children, earning 1,800 roubles a month with that of an English professor's family with a salary of £100 a month or £1,200 a year. The official equivalent of 1,800 roubles is £70. To facilitate the comparison, I assume that both families live in flats.

U.S.S.R. (Kharkov, Ukraine)	per month roubles
rent and services	120
(3-room flat with bath, kitchen and telephone)	
central heating	20
(yearly average)	
taxes and health insurance	50
4 per cent State loan ..	150
clothing	250
laundry	50
food and household ..	700
cigarettes	100
1 servant	60
sundries	300
	1,800

England (London)	per month £	per ann £
rent and rates ..	15	180
(5-room flat with bath and kitchen)		
coal, light, telephone	4	48
income tax	12	144
life insurance ..	5	60
(5 per cent of income)		
clothing	8	96
laundry ..	1	12
food and household .	24	288
tobacco and cigarettes	2	24
2 servants	8	96
education	7	84
doctor and dentist ..	2	24
sundries (car, etc) .	12	144
	£100	£1200

Education and medical service are free to all in the U.S.S.R. The clinics are served by the best specialists, and I have not found them overcrowded; for example, I have never had to wait more than 15 minutes at the dentist's, even if I came without an appointment. Moreover, urban transport, which is very expensive in England, costs practically nothing in Russia. In most cases a professor has a car at his disposal.

The monthly consumption of food, comprised in the 700 roubles mentioned in the list, includes the following:

Milk	50 pt.	Bread	40 lb.
Butter	20 lb.	Potatoes	100 lb.
Eggs	150	Vegetables	100 lb.
Meat	20 lb.	Fruit	50 lb.
Fish	20 lb.		

The items here listed cost 500 roubles in 1937 and refer to goods of the best quality, which are well up to English standards. The prices are falling steadily.

Cheap clothes are of poor material and good clothing is expensive. Scientific men and their families usually prefer a small assortment of good quality. Dress suits are not worn except by waiters.

Holidays are usually spent in the Caucasus or on the Black Sea coast, which are equivalent to Switzerland and the Mediterranean.

M. RUHEMANN.

30, Clifton Gardens, W.9.

A Binocular Illusion

IF an observer views a piece of linoleum, or pavement, marked out as a checkerboard in light and dark squares, it is possible by causing the lines of vision of the two eyes to converge, that is, locating the fixation point, above the linoleum, to produce the impression that the pattern is raised above the level of the floor, and that it is on a smaller scale than that of the actual linoleum. This occurs when the images of two neighbouring dark squares fall on the corresponding points of the two retinas. A still smaller pattern at a still higher level may be produced when the images of two dark squares, separated actually by two light and one dark square, are caused by suitable convergence to fall on corresponding points of the two retinas.

This illusion is probably known to many, but I can find no description of it in any general or ophthalmic physiology I have been able to consult; and it may be of interest that the phenomenon was brought to my notice by a boy aged nine years. He had discovered it quite independently for himself.

The raised patterns thus produced are seen to shift as the observer moves his head, as may be easily confirmed geometrically.

Some Observations on the Rotating Pendulum

THE observations by Lythgoe[1] on the 'rotating pendulum' are almost entirely in accord with the hypothesis that the 'latent period' of vision varies in the same sense as the concentration of photochemical substance in the retina of the eye, and is controlled mainly, if not entirely, by this concentration. The concentration of photochemical substance is decreased (*a*) by a general increase in illumination of the field of view; (*b*) by the contemporaneous presence of one or more glare sources in the field of view; (*c*) by the previous presence of glare sources in the field of view. In case (*c*), of course, the concentration of photochemical substance is steadily returning to its equilibrium value in the absence of glare sources.

Lythgoe has found a relative decrease in the latent period when any one of these three conditions is applied to one eye of a subject. The case of dark adaptation of one eye does not appear to fall into line with this hypothesis, though more exhaustive experimental work might clear away the discrepancy.

If the above hypothesis is true, the observations of Lythgoe are of considerable interest, as they would provide a simple and instantaneous measure of the concentration of photochemical substance in the retina of the eye.

Clay in a Vegetable Diet

MESSRS. Lawson and Moon record in NATURE of January 1 (p. 40) the eating of clay by Quetchua Indians from Lake Titicaca, South America. A similar clay is eaten by the Baganda, who are also vegetable eaters, their staple food being plantains and sweet potatoes. The use of the clay appears in this case to be confined to pregnant women and is eaten after work almost as a sweetmeat, the clay having first been smoked in the hut fire.

Points from Foregoing Letters

COMMENTING on the proposed Society for the study of the Social Relations of Science, Prof. F. Soddy stresses the need of paying attention to the working of the monetary system and for strong leadership on the part of scientific workers.

Using new methods of applying constant lateral pressure to monomolecular surface films, Dr. J. H. Schulman, E. Stenhagen and Prof. E. K. Rideal have studied the formation of complex films by injecting dilute solutions of substances such as cetyl sulphate and digitonin into the substrate (water solution) upon which a film of cholesterol is spread. They find that the increased area of the film due to penetration of the second substance is, under controlled conditions, in a simple ratio (1 : 1, 1 : 2 and 1 : 3), depending upon the structure (ring or chain) of the organic molecules involved. Several factors apart from surface pressure, namely, bulk concentration and pH, affect the formation and stability of the complex surface film.

The ratio of the initial intensities of the two (presumably) isomeric radioactive forms of rhodium, with periods of 44 and 244 seconds, obtained by bombardment of rhodium with neutrons, are deduced by Dr. B. Pontecorvo from the total activity: (*a*) with a source of radon plus beryllium in the presence of paraffin, and (*b*) with radon plus beryllium placed on the axis of the cylinder of rhodium in the absence of paraffin. In the first case the ratio was eleven, agreeing with that found by Segrè. In the second case (where the mean energy of the neutrons was less than 10^5 e.v.) the ratio found was six.

The generalization that mesomeric systems may be readily formed from others closely related to them throws light, according to Prof. J. Kenner, on many organic reactions such as the formation of azoxybenzene, transition from methyl diazohydroxide to diazomethane, the facile oxidation of nitroso-benzene to nitrobenzene, the formation of unsaturated systems such as stilbene from dibenzyl, the various syntheses of polyenes, etc.

When oxygen is bombarded with deuterons (of 2 M.e.v. energy) two radioactive substances are produced, one with a period of 90 seconds which has been identified as due to fluorine of mass 17 and another with a period of 120 minutes. Chemical separation shows this to be due to an isotope of fluorine of mass 18, according to T. Yasaki and S. Watanabe. The upper limit of the energy of the positrons which it emits is 0·7 M.e.v., and the authors discuss the possible nuclear reactions by which it may be formed.

Photographs of twilight spectra and interference pictures of the twilight yellow radiation are submitted by R. Bernard to prove the presence of sodium in the high atmosphere. The *D*-lines of sodium can also be detected in the night sky spectrum.

The electrical potential difference obtained when two aqueous salt solutions of different concentrations are separated by a non-miscible oily solution are due, according to G. Ehrensvärd and L. Gunnar Sillén, to absorption potentials (that is, to the accumulation of oppositely charged ions on the two sides of the oil-water interface), rather than to the difference in the concentration of the ions in the bulk of the liquid. The authors submit a formula which, they state, agrees with the experimental results, and suggest that absorption potentials play a part in taste and smell sensations.

Dr. F. G. Mann and A. Litherland discuss the preparation and relationships of various amino-derivatives of pentaerythritol, including tetrasulphonamido-, bi-quaternary iodide-, and chloro-compounds.

The preparation of the enzyme uricase in a greatly purified form is reported by Dr. J. N. Davidson. The purest preparation contains 0·15–0·18 per cent iron and has a specific activity, under stated conditions, of 85 c.mm. per mgm. enzyme per minute.

E. Adler and Prof. H. v. Euler find that the lactoflavin, extracted by water from the retina and pigment layer of the eye of a codfish, is not taken up by benzyl alcohol when shaken with that solvent. They conclude that the pigment is not in the form of a phosphoric ester, serving as oxidation-reduction catalyst, but occurs in the form of free flavin, which by its fluorescent and light-sensitive properties may take part in the visual processes.

Spore formation is reported by Dr. R. L. Starkey in *Vibrio desulfuricans*, the bacterium which reduces sulphate to sulphide. The temperature of incubation seems to exert a marked effect on sporulation. This is claimed to be the first definite evidence of spore-formation by bacteria of the morphological group to which this and also the cholera organism belong.

Research Items

Clactonian Implements

On the basis of excavations at Jaywick Sands, Essex, in 1934 Mr. Kenneth P. Oakley and Mrs. Mary Leakey have discussed in detail the position of the Clactonian industry with special reference to the fauna and geological evidence of the Clactonian channel (*Proc. Prehist. Soc.*, 1937, **3**, 2). The deposits of the foreshore exposure of Pleistocene deposits at Clacton and Lion's Point were made famous through the investigations of Mr. Hazzledine Warren, and the gravels in the Clacton channel have yielded a contemporary palæolithic flake industry, which was recognized by the Abbé Breuil as identical in style with that of the gravels of the Middle Pleistocene of Mesvin, Belgium. To this the name of Clactonian has been given, and the style has since been recognized in many localities both in Britain and on the Continent. It is a widespread culture, possibly of Asiatic origin, and probably ancestral to Mousterian. The industry of the type station, Clacton-on-Sea, represents neither the earliest nor the latest stage, and it is important to establish its exact position in the Lower Palæolithic sequence. This involves an exact correlation with the terrace succession of the Lower Thames Valley. Warren has claimed that the Clacton deposits belong to the earlier part of the Taplow Terrace group, whereas Breuil has correlated them with the early Boyn Hill, or 100 ft. terrace. As a result of the present investigations it is concluded, especially on the evidence of the fauna, that the Clacton channel deposits belong to the same inter-glacial period as the 100 ft. terrace of the Lower Thames. The flint industry points to the same conclusion. A comparison of the industries of the two leads to the view that the type Clactonian industry is intermediate between the Clactonian industry of the Lower Gravel and the flake industry represented in the Middle Gravels of the 100 ft. terrace at Swanscombe. As regards the geological evidence, it is clear that the low level of the Clacton channel requires special explanation, if, as the evidence suggests, they post-date the Lower Gravel but predate the Middle Gravel. The only feasible explanation is an interruption of the aggradation of the gravels of the 100 ft. terrace by a phase of rejuvenation of the river, which resulted in the cutting of a sunk-channel in the lower reaches of the valley.

Cones from the Dutch East Indies

The posthumous work of Dr. Ph. Dautzenberg on the genus *Conus* (Résultats Scientifiques du Voyage aux Indes Orientales Néerlandaises de LL.AA.RR. le Prince et la Princesse Léopold de Belgique. Mémoires du Musée Royal d'Histoire Naturelle de Belgique, Hors Série, Vol. 2, Fascicule 18. Gastéropodes marins. 3—Family Conidae, 1937) was completed by Dr. E. Leloup and is now issued in a very handsome volume, a companion to the former work on the families Terebridæ and Mitridæ of this same series. There is an enormous amount of work involved here, with pages of carefully noted synonymy and criticisms, and some beautiful coloured plates. In 1937, Mr. J. R. le B. Tomlin published his catalogue of recent and fossil cones (*Proc. Malacol. Soc.*, 27; 1937) and there is not one species of those from the Dutch East Indies not included in this list, there being no new species. The genus *Conus* is so well known to conchologists that this is not at all surprising. The two authors are not always in complete agreement as to the authority for the species, although in most cases these coincide.

Phyllirhoidæ of the John Murray Expedition

These are described by H. G. Stubbings (John Murray Expedition 1933–34. Scientific Reports, 5, No. 1; 1937. British Museum (Natural History)). The family is represented by five specimens belonging to a new species of *Cephalopyge*, namely, *Cephalopyge arabica*. It is interesting in that it incorporates characters hitherto regarded as diagnostic of one or other of the two subgenera of *Cephalopyge* recognized by Thiele (1931). A detailed description of this new species is given and also a systematic revision of the genus. The family Phyllirhoidæ is divided by the author into two genera, *Phyllirhoë* and *Cephalopyge*, and a key is given to the species of the latter genus, of which there are four now recognized, two of which possess a radula and two, including *C. arabica*, are without it. Their distribution is almost world-wide in tropical and subtropical waters. They are all very small and all the records for which the time of year is known lie within the period autumn to winter in both northern and southern hemispheres. Mr. Stubbings suggests that it is probable that the species become adult, when they are a size most likely to be captured, during the autumn, and live through the winter. "The next generation would then be undergoing its larval development during the following summer when food conditions would be at their best." The specimens of *C. arabica* are from localities near the equator where there is no winter as such. They were obtained, however, during the period of the north-east monsoon, which is the coldest period of the year in the Arabian Sea.

Origin of Octoploid Wheat

The origin of an octoploid wheat has been described by Dr. G. S. Bhatia (*J. Genetics*, 35, No. 3). Reciprocal crosses were made between *Triticum vulgare* var. *graecum* and a new variety of *T. dicoccum* (Khapli emmer) from the Central Provinces of India, which is described under the name var. *Indicum*. It differs from other Indian varieties in having pubescent glumes and three awns per spikelet. The writer concludes that emmer wheats originated not in Abyssinia but in the Eastern Mediterranean region between Caucasus and Palestine. Khapli × *vulgare* gave 60 per cent setting of grain while the reciprocal gave only 40 per cent, the latter seeds being also much smaller. From 30 seeds of Khapli × *vulgare* only one germinated and it soon died. Three seeds from *vulgare* × Khapli were much larger than the rest and were sown separately. One of them germinated to produce the sturdy octoploid. The remainder produced 11 pale seedlings, all of which died within two months. The octoploid with 56 chromosomes probably came from a diploid egg of *vulgare* uniting with a haploid male cell from *T. dicoccum*. This plant resembles the Khapli parent in habit and grain colour, but in the shape of the glumes, ears and awns it resembled the *vulgare* parent. The plant showed regular meiosis with 28 bivalent chromosomes and produced good seeds.

Lintless Mutations in Cotton

A LINTLESS condition occasionally arises as a mutation in cotton. Seven types of lintless Asiatic cottons are described by Messrs. J. B. Hutchinson and P. D. Gadkari (*J. Genetics*, 35, No. 2), originating in strains of *Gossypium Mollisoni* (*G. arboreum* var. *neglectum*), in different parts of India. It is shown that at least four independent genes are involved, two of which are complementary genes for glabrous lintless, in which the plants produce no hairs of any kind, and two complementary for hairy lintless. Three represent independent mutations at the same locus. No satisfactory evidence of linkage was found, but there was strong association of another kind between a lintless gene, in the Punjab type, and leaf shape. In one lintless type the plants have almost full strength when grown in the mild climate of Trinidad, but in Central India they are semi-lethal. The Punjab lintless type has in eight generations undergone a remarkable change in the homozygote from complete lethality to complete viability. How this change took place is not clear, but its relation to theories of change of dominance is discussed.

The Apple Scab Fungus

THE fungus *Venturia inaequalis* is the cause of one of the major diseases of the apple crop. Two main sources of infection have been recognized, namely, pustules of conidia upon year-old wood, and ascospores from perithecia upon dead leaves of the previous season. Mr. R. McKay now shows (*Sci. Proc. Roy. Dub. Soc.*, 21, No. 57, 623; 1938) that a third source of infection in orchards at Glasnevin, Dublin, lies in bud scales which harbour the fungus. These provide a virulent source of conidia very early in the spring, when the young leaves first appear. It is possible that such a method of overwintering might explain many puzzling outbreaks of the disease in other regions. Attention of growers is directed to the control of bud infection by spraying with Bordeaux mixture or lime-sulphur. This is the usual method, but it should now be possible to apply it with more insight, and assess its action more exactly.

Secondary Causes of Earthquakes

Two papers have recently been published on the secondary causes of earthquakes. One, by V. Conrad (Union Geod. Geoph. Intern., Publ., Ser. A, fasc., No. 15, 118–123; 1937), deals with the effects of variations in atmospheric pressure. On a map of the epicentres of earthquakes in Hungary during the years 1919–28, plus signs are inserted at the epicentres when the pressure was rising during one or two days before the earthquakes and minus signs when the pressure was falling. The distribution of the signs in zones shows that the activity of the foci is affected by changes in atmospheric pressure. On the other hand, the earthquakes of the Menstrie and Invergarry districts in Scotland show no such effects (see NATURE of January 22, p. 167, for a note on similar zones in New Zealand). In the second paper (*Bull. Seis. Soc. Amer.*, 28, 15–22; 1938), R. Z. Kirkpatrick has examined the effects of tidal variations on the occurrence of 105 earthquakes recorded at Balboa, at the Pacific entrance of the Panama Canal. He finds that 30 earthquakes occurred within 1½ hours of low tide and 27 within 1½ hours of high tide. The average high tide for the year at Balboa is + 10·7 ft. and the average low tide − 10·5 ft.

Blue Solutions of Cobalt Chloride

MANY investigations have been carried out with the view of explaining the blue colour encountered with solutions of cobalt chloride under certain conditions. It has been suggested that the ion $CoCl_4^{--}$ is formed; also, that the colour is due to a different state of hydration of the cobalt ion. A recent paper by Pearce and Dawson (*J. Chem. Phys.*, 6, 128; 1938) contains a new explanation based on observations of the effects of adding different concentrations of hydrochloric acid, alkali and alkaline earth chlorides on the absorption spectrum of cobalt chloride. It has been found that the characteristic band is widened by the added salt, and that the extent of widening depends directly on the ionic charge and inversely on the ionic volume of the added cation. This increased absorption of light and consequent colour change is found to bear an intimate relation to the degree of hydration of the added cation. Equimolal concentrations of added chlorides do not produce equivalent colour changes, indicating that the formation of complex ions of the type, $CoCl_4^{--}$, is apparently not an adequate explanation. In dilute solutions the cobalt ion is strongly hydrated and the sheath of solvent surrounding it prevents it from approaching closely to the chloride ions. When strongly hydrating ions are added, they attract solvent molecules and thus render it easier for the cobalt and chloride ions to approach under the influence of electrostatic attraction. Under these conditions it is assumed that the chloride ions exert a distortion on the electronic system of the cobalt ion, causing it to absorb at a different wave-length, that is, to exhibit a different colour.

Lantern Adaptor for Film Strips

IN recent years, optical lanterns and their accessory parts have undergone a number of improvements. A new device which has been submitted to us is Dance's Patent Adaptor, by means of which film strips can be projected by any lantern or epidiascope as simply as glass slides. Film strips have many advantages over glass lantern slides: copies are much cheaper, there is no fear of breakage, storage room is negligible and as many as sixty pictures may be sent through the post for 2d. As the size of the picture has been laid down by the British Standards Institution, use of the film strip instead of the glass slide is likely to increase. With the adaptor referred to are supplied seven glass slides, each capable of holding four frames or pictures of the film strip. By this means the teacher or lecturer is not held to the order of the pictures comprising the complete strip but can select his own pictures, either from one film strip or a number of strips, in exactly the same way as he now selects his lantern slides from a number of sets. There are usually from twenty-four to thirty pictures on a strip, and these can, of course, be projected in the order in which they occur on the strip instead of cutting them up into sets of four. The whole adaptor, together with the glass slides, is packed in a box 7 in. × 5 in. × 2 in. in size. Particulars of the device can be obtained from Messrs. Pelly and Healey Ltd., 61/63 Blandford Street, W.1.

Precision Gauge for Measuring Liquid in Tanks

THIS gauge has been designed by Messrs. Negretti and Zambra in conjunction with the Production Department of the Iraq Petroleum Company for the measurement of bulk quantities of crude petroleum, or products derived therefrom, when contained in storage tanks of uniform cross-sectional area. It consists essentially of a manometer in which a mercury column is used to measure the equivalent weight of the head of oil. The gauge is rigidly mounted and two spirit levels are provided for levelling purposes. Other features include special illumination to obtain sharp definition of the mercury meniscus, vernier and scale for accurate measurement of the length of the mercury column, and thermometer for determining the temperature of the gauge. Each instrument is calibrated by the National Physical Laboratory. In addition, tables are supplied for correcting gauge readings to a standard temperature and for the conversion to equivalent weights of oil. All measurements are made from a fixed datum level and an overall accuracy within 0·005 inch is guaranteed. The range of the gauge is from 0 to 36 inches of mercury. The instrument facilitates measurement of oil in bulk and should find a wide application in the petroleum industry.

Pipe Thermostat

A PIPE thermostat has been designed by Messrs. Negretti and Zambra, which is intended for use where it is desired to operate certain mechanism whenever the temperature of the fluid in the pipe rises or falls outside predetermined limits. It is robustly constructed and is clamped to the outside of the pipe. Models are available to suit pipes from $\frac{1}{2}$ to 6 inches in diameter with one of three temperature ranges: 0–100° F., 100–200° F. or 200–300° F. The minimum differential is $\pm 2\frac{1}{2}$° F. of the setting point.

Higher Magnetic Permeabilities

THE magnetic permeability of a substance is the ratio of the magnetic flux density through the substance to that through air for the same magnetizing force. In the *Bell Laboratories Record* of March, R. M. Bozorth tells how a substance has been found experimentally which has ten times the permeability of the best commercial permalloys available. Since the discovery, more than twenty years ago, that certain alloys of iron and nickel have remarkable magnetic properties, the factors which control this unusual behaviour have been very carefully studied with the object of still further increasing the permeability. The material found was a single crystal of permalloy which contained 66 per cent nickel. This was purified by heat treatment at a high temperature in hydrogen, then cut so that its permeability could be measured. It was heat-treated again and afterwards at a relatively low temperature in a magnetic field. After this preparation, the permeability of this crystal was 1,330,000 for a definite magnetizing force. Although at present it seems improbable that commercial use will be made of single permalloy crystals, some of the factors which make for high permeability, such as crystal orientation, heat-treatment and chemical composition are commonly used in manufacturing magnetic materials. Recently some factories have begun to roll transformer sheet so that the crystallographic directions are aligned in desired directions of easiest magnetization with respect to the dimensions of the sheet. There is a distinct possibility that heat-treatment in hydrogen at a high temperature and in a magnetic field at a relatively low temperature will in the future be of value commercially.

Radioactive Constants of Uranium and Radium

IN a short paper (*Anz. Akad. Wiss. Wien*, No. 3, 7; 1938), S. Meyer discusses the mutual consistency of recent determinations of the radioactive constants of uranium and radium. The sources used in such determinations are calibrated by comparison with one of the international radium standards. In 1934, the standards at Vienna and Paris were replaced by new ones prepared by Hönigschmid, who also prepared standards for other national laboratories. Intercomparison of the old and new standards has not revealed any significant difference between them; some of the new standards are a few parts in a thousand larger than the old ones, while others are smaller by the same amount. It is suggested that measurements be referred to the old Vienna and Paris standards, which appear to have exactly the same value. In terms of these standards, the number of particles emitted per second by one gram of radium is $3\cdot68 \times 10^{10}$. Owing in part to errors of calibration of the sources, the accuracy of this measurement is not more than 0·5 per cent. Measurements of the corresponding quantity have been made in the case of uranium by Schiedt and by Kovarik and Adams. In order to relate these to the constant for radium, they have to be corrected for the α-particles emitted by U II and by actino-uranium. It is shown that, while Schiedt's corrected value is consistent with the radium : uranium ratio found in old minerals, Kovarik and Adam's value is too low. These considerations suggest that the most probable values of the constants for U I and Ra are: half value period: U I, $4\cdot58 \times 10^{9}$ years; Ra, $1\cdot59 \times 10^{3}$ years; number of α-particles emitted per gm. per sec.: U I, $1\cdot214 \times 10^{4}$; Ra, $3\cdot68 \times 10^{10}$; Ra/U equilibrium ratio $= 3\cdot3 \times 10^{-7}$.

Inclinations to Line of Sight of Non-Galactic Nebulæ

MR. F. G. BROWN has recently published a paper with this title (*Mon. Not. Roy. Astro. Soc.*, 98, 3; Jan. 1938), his study being based primarily on the catalogue of the Herschel nebulæ north of declination $-20°$, measured at Heidelberg on plates taken with the Bruce 40-cm. portrait lens and the 70-cm. reflector. All non-galactic nebulæ of 2′ diameter and greater have been extracted and classified from this catalogue, a total of 593, and these reveal an apparent large excess of small inclinations to the line of sight. In addition, 109 other nebulæ within the area covered by the catalogue down to the limiting diameter reveal the same characteristic. Although E. Öpik suggested some fifteen years ago that photographic selection is responsible for the excess of small inclinations, Mr. Brown shows fairly conclusively that this is not so, and that there is probably a real systematic orientation of the planes of the nebulæ in space.

The Rivers of India

THE material welfare of the people of India has always been in unusual measure dependent upon the amount of water available for agricultural operations at the right season. This fact chiefly led Prof. M. N. Saha to devote his recent presidential address to the National Institute of Sciences in India to "The Problem of Indian Rivers", for, as he points out, 66 per cent of the population are peasants and a further 23 per cent are villagers mainly dependent on a rural economy. While the normal rainfall suffices in parts of India to nourish the prevailing agriculture, the fact remains that this must be supplemented wherever possible by storage in 'tanks', as in most of the Deccan, by utilization of subsoil water from wells, and by the great canal systems providing irrigation water from the large rivers of the Indo-Gangetic Plain and the eastern coastal plain. The distribution of population density, therefore, may be very closely correlated with those of rainfall and irrigable land. Prof. Saha cites the estimate that of the total rainfall 60 per cent is evaporated, and of the 40 per cent which passes to the ocean only 6–8 is used for irrigation. He pays tribute to the long-sustained interest of the Government in irrigation as leading to the huge total investment of 150 crores (more than 113 millions sterling) in new works and in repairs to old works; but he quotes the Central Irrigation Board's report that, of the 30 million acres irrigated from artificial canals, 8 million, lying chiefly in Bengal, Bihar and Orissa, are 'unproductive', that is, produce no profit for the irrigation authority.

The lateral movements of river beds on alluvial plains is of course recognized as a gradual process incessantly at work, and the same is true of the downstream migration of meanders. Nevertheless, there are reasons for believing that in northern India deep-seated crustal movements account for some of the more spectacular hydrographic changes. Prof. Saha gives examples of the effects of river change in this region. Pataliputra, the capital city of India from the sixth century B.C. until the fifth century A.D., owing its importance to its position at a focus of communications along five rivers, now lies buried 17 ft. beneath the modern Patna. Gaur, 160 miles north of Calcutta, which as Pataliputra's successor was estimated to have contained more than two million people in the fifteenth century, is now smothered in jungle. The suggestion is made that its evacuation was due to sinking, slight but sufficient to render it unhealthy. Moreover, such subsidence relative to surrounding deltaic land seems to merit investigation, since it is reported from Calcutta, where the level is said to have declined from 2 ft. to 4 ft. in the last two centuries, and this has called for pumping to assure the discharge of sewage. Finally, the well-known disastrous effects of river changes of the Ganges-Brahamaputra delta are cited, by which the eastward migration of live rivers has left the western areas seamed with channels intermittently filled, and so with abundant stagnant pools leading to malaria and decadence of the region. How far this natural process could have been prevented is uncertain; but it is claimed that in one section at least, the Burdwan division, which lost nearly half its population from malaria between 1860 and 1870, the harm was due to an artificial cause, the building of the railway embankment without proper study of the consequences to the hydrology.

In stating that construction of weirs and bridges has too often been undertaken after insufficient and too localized study of the rivers, Prof. Saha quotes Sir Francis Spring in his plea in "River Training and Control", that the State ought "by consistent, logical and well-organized research to learn something more definite than is now known about the physics of long reaches of rivers". This in the nineteenth century; only within the last decade has effect been given to the suggestion and so far only by two provinces. The Punjab has its Irrigation Research Institute at Lahore, and Bombay has installed a hydrodynamic research station near Poona. No such laboratory exists as yet in the eastern provinces, where the need for hydrological research would seem to be greatest.

Prof. Saha concludes his address with a striking vision of India regenerated, socially and economically, by a process of industrialization analogous to that now under way in the U.S.S.R. In reviewing the present backwardness of Indian labour conditions he attempts an assessment of energy expended, and finds the amount per head per year to be less than 90 of the units adopted (man-power 60, animal 10, steam and oil 10, electricity 7). This he contrasts with Japan, 6–8 times greater, and Norway, nearly 19 times greater. He notes the vast increase in Russian output of electricity from 15 units per head in 1919 to about 300 in 1937, with a corresponding increase in the proportion of industrial population; and he considers that this points the way for India. He then discusses the very high average cost of the half-million kilowatts of electric energy already installed in India, which represent only about 2·5 per cent of the hydro-electric resources, if Meares' estimate be accepted, and he cites cases of installations unduly costly owing to inadequate study. The time is therefore ripe, he submits, for a systematic survey of water-power resources following the Russian plan of attack, for he holds that cheap power will go far to eliminate the root cause of poverty in India. It may be noted, however, that he here leaves many sides of the population problem untouched.

Nevertheless, Prof. Saha has directed attention to certain facts that appear to be insufficiently appreciated: that rivers possess strong individuality in the character of their basins and in their regimens; that the proper unit of study is the entire catchment area; that the uses which they offer to man—power, transport, supply for irrigation and industry—as well as the menaces of flooding and silting, are all closely interrelated; and finally, that the dependence of the Indian people upon the rivers is so tremendous that the whole subject merits thorough investigation. In conclusion, it may be noted that the question of soil fertility is intimately bound up with those which he discusses. Systematic observation would appear to be requisite throughout each basin upon such matters as soil erosion on one hand and silting on the other, as well as on the variations in the depth of the water table and their bearing upon alkaline and other incrustations.

Soil Toxicity in the Dorset Heaths

A MEETING of the British Ecological Society, presided over by Prof. A. G. Tansley, was held on April 20, in the Department of Botany, Bedford College, Regent's Park, London, N.W.1. The entire meeting was given to consideration of the problems of soil toxicity and its amelioration in the Dorset heaths. The researches now in progress have come about as a result of observations and experiments initiated by Dr. M. C. Rayner in the Wareham neighbourhood in 1931 on the lands of the Forestry Commission now known as Wareham Forest.

A considerable tract of country around the town of Wareham in Dorset is occupied by heathland. Certain areas of this were acquired by the Forestry Commission and sown with several species of pine in 1924–27. These original sowings gave very poor results, the seedlings for the most part showing no growth or dying outright. In addition, there were many puzzling inconsistencies of behaviour.

The meeting was opened by an informal account by Prof. Neilson Jones of some of the characteristics, including that of apparent toxicity, associated with Wareham soil, and was followed by a general summary by Dr. Rayner of the field and laboratory researches at Wareham Forest that have led to the present situation. Some of the exhibits, relating to mycological and mycorrhizal problems arising from the field experiments, have an important bearing on the nutrition and healthy growth of conifers in cultivation, for example, those on Sitka spruce and Lawson's cypress.

The accounts of the work were supplemented by a large number of well-displayed demonstrations illustrating various phases of the research work in progress. Among these were demonstrations of the inhibition of seedling and fungal growth by soil factors, growth effects produced by the addition of raw cellulose to soils, epinastic curvature reactions induced by soil constituents, the incidence of 'fused needle' disease, and the effects on seedling growth produced by soil inoculation with humus or mycelium from pure cultures.

Also illustrated were the remarkable effects on growth brought about by the use of certain organic composts on Wareham soil, with some of the evidence supporting the hypothesis that led to their use and now put forward to interpret their action. Pure cultures of a number of mycorrhizal and associated soil fungi were displayed.

A general discussion followed inspection of the demonstrations, in which a number of visitors and members of the Society took part.

In his concluding remarks, Prof. Tansley pointed out that a meeting such as that just held, in which the Society visited an institution to hear about the research work in progress there, was an innovation; the results of the experiment led him to hope that other meetings of the kind would be arranged in the near future.

Faunistic and Hydrographic Changes

By B. Storrow, Dove Marine Laboratory, Cullercoats, Northumberland

THE following faunistic records are of interest in connexion with recent hydrographic changes as described in the reports of the International Council for the Exploration of the Sea. Abnormal activity of Atlantic waters around the north of Scotland will bring oceanic and western species into the northern North Sea. When this activity is followed by a southerly extension of the influence of the Norwegian sea the recent additions to the fauna can be expected to retreat to the Atlantic or to move southwards before the influence of the colder waters. In this southerly movement before the advance of cold conditions they will be followed by the fauna of the colder waters. Records of a mixed fauna may be found still farther south after a suitable interval. The above outlines the probable cause for the following records which have been obtained for the Northumberland coast. Unless otherwise stated, the specimens mentioned have been obtained from North Shields trawlers.

Geryon tridens Krøyer. 25–30 years ago this crab was commonly called the Fair Isle pilot by North Shields skippers, who did not find it in their trawls until reaching the vicinity of Fair Isle. To the best of our knowledge it has not been recorded for the waters off Northumberland. The first specimen was obtained April 29, 1935, 31 miles N.E. ½ N. of the Tyne, which is to the east of Coquet Island. The second specimen was found on March 10, 1936, and the trawler had been fishing 10 miles N.E. ½ N. off the Tyne. No further records were obtained until October 1937, and from then until the end of the year 49 specimens were brought to the Laboratory from trawlers fishing off our coast. Some of these crabs are living in our tanks.

Chimaera monstrosa L. As a general rule, North Shields trawlers do not get the rat-fish until reaching the latitude of Aberdeen or thereabouts, and then not frequently. One was taken 10½ miles N.N.E. of the Tyne, January 22, 1938.

Urophycis blennoides (Brunnich). The greater fork-beard has never been a local fish and its presence in the catch of a North Shields trawler was associated with fishing in more northerly waters and often in the vicinity of the Norwegian deep water. One was caught 14 miles east-north-east of the Tyne, June 15, 1936.

Pristiurus melastomus (Rafinesque). According to Smitt the black-mouthed dogfish has a wide range and has been taken occasionally off the Norwegian coast and in the Skager Rack and Cattegat. One was taken in 42 fathoms east of Coquet Island, April 30, 1937.

Centrolophus niger (Gmelin). The black-fish of Couch is considered a fish of the Mediterranean and Atlantic. Occasional stragglers have been taken off our south coast and Day refers to specimens from the Northumberland and Yorkshire coasts. One of 56 cm. was taken on Berwick Bank, October 25, 1937.

Cetorhinus maximus (Gunner). It is generally supposed that the basking shark migrates northwards along the Atlantic seaboard as far as the Norwegian coast after its appearance off the west coast of Ireland in spring. Occasionally it enters the North Sea. One, 10 ft. 11½ in. in length, was caught in salmon nets, 2 miles off Souter, on June 13, 1934.

Ctenolabrus rupestris (L.). The goldsinny is found along the Atlantic coasts of Europe from the Mediterranean to Trondheim and in the southern Baltic. It has been recorded for Northumberland and Yorkshire, but not in our time. A specimen caught on July 3, 1935, 20 miles north-north-east of the Tyne, is living in the aquarium. Another was picked up on Whitley sands, January 31, 1937.

Maurolicus muelleri (Gmelin). The pearl-side has a wide distribution. According to Smitt, it has been found on both sides of the Atlantic and from the coast of Finmark to that of Sweden. It also enters the North Sea. It is far from common off our coast. Three specimens have been picked up on the sands of Cullercoats and Whitley Bay recently in March and April; one in 1936 and two in 1937.

Science and Industry

A SERIES of lectures arranged by the London Branch of the Association of Scientific Workers on the subject of science and industry has recently come to its conclusion. These lectures were arranged by the Association with the object of directing attention to the application of scientific methods and developments in industry, and the possibility of increased application; the allied question of the organization of research; and the question of the best types of scientific education to fit men for technical positions in industry.

The first lecture was given by Sir Richard Gregory. He opened with an enumeration of some of the outstanding benefits that science has conferred on society, and showed how the developments of industry have depended upon the developments of creative science. The extent, however, to which scientific discovery is used for industrial progress depends upon the capacity of industry to understand the results of research and the power to use them. The general principle that expenditure on science is a profitable investment may be said to have been conceded, but as yet science is not used as fully as it may be. Forty years ago the expenditure of the British Government on scientific investigation was about £45,000; at the present time the total amount is nearly two millions, of which the Department of Scientific and Industrial Research administers about £600,000. Sir Richard quoted a memorandum presented by the Parliamentary Science Committee, and supported its argument that the provision for scientific and industrial research in Great Britain is inadequate and that a bolder and broader financial scheme is needed.

Sir Richard went on to plead for the employment of men with scientific training and knowledge as directors and administrators. Industry suffers from administrators who have not a scientific outlook and do not realize the value of long-sustained expenditure on scientific research, although he admitted that it is difficult to find men who combine specialized knowledge on scientific and technical subjects with organizing or administrative capacity.

Sir John Russell traced the application of science to agriculture from the early investigation into artificial manures carried out on the same land now occupied by the Experimental Station at Rothamsted to the present day, when such research demands the knowledge of chemists, physicists, botanists, biochemists, pathologists, etc. The development of agriculture has not been devoid of chance discoveries, particularly in the development of wheat and in the use of such things as Bordeaux mixture, devised to scare away predatory boys. There has, however, been great advances in the knowledge and control of the processes of Nature as a result of the patient detailed work that has been carried out. Besides the effect of the well-known artificial manures, it has been discovered of recent years that traces of certain inorganic salts such as the compounds of cobalt and boron have a marked effect on the plant life and the subsistent animal life.

Under the title of "Science in the Chemical Industry", Major F. A. Freeth indulged in alternate attacks on and justification of the existence of industrial scientific workers. The attacks were, however, more of the nature of constructive criticism. That the existence of men of science is justified there is no doubt; but there is doubt whether they have the right attitude to their tasks. Men of science as a body lack rhetoric—they do not know how to capture the enthusiasm of the general public.

The chemical industry itself is the only industry that takes its name from the science on which it is based. It should properly be called the 'molecular industry', for it is chiefly the scientific study of the behaviour of molecules which forms the basis on which the large industries are built. Some of the heavy chemical industries date back for decades, but the modern organic chemist owes everything to the patient hard work of investigators which is continuing all the time. Fundamental scientific theory is required for any new development in the chemical industry, but before it can be put into practice it must be translated into terms of large-scale plant and teams of men, and there is often a considerable time-lag between the adoption of a new method and its achievement in practice.

Dr. E. A. Rudge spoke on the subject of training for the chemical industry and chemical engineering; and described an investigation he had conducted to find out the requirements of a number of chemical industries by way of recruits to their scientific staffs. With the great increase in scientific control in industry there has arisen a demand for a varied army of scientific workers, ranging from routine semi-skilled testers to fully trained research specialists. By means of a questionnaire Dr. Rudge has gained information that shows the distribution of the demand for scientific workers in the different grades.

This investigation produced the following main conclusions. A large proportion of the chemical firms in the area investigated employ small laboratory personnel (less than ten employees). These small organizations commonly employ unqualified recruits, and it is in the main the larger laboratories that require graduates and research workers. A great preference is shown for recruits of about matriculation standard with a knowledge of industrial method and technique. For every graduate required for the specialized work of research development more than nine undergraduates are required for laboratory routine. The question of the training of these unqualified employees is one that requires greater co-operation between industry and teachers, especially in the technical colleges.

Dr. F. S. Sinnatt, speaking on the Fuel Research Coal Survey, said that the work of the Department of Scientific and Industrial Research can be divided into two sections: the utilization of coal, and the survey of the coalfields of Great Britain. Different types of coal are needed for use in coking, gas manufacture, steam raising, household use and hydrogenation; wide variation may occur in the composition of a seam within the area covered by one mine, with consequent changes in its suitability for these different purposes. The control of such variation is of primary importance to the consumer and must be the basis of any improvement in the utilization of coal.

As a result of the work already done, it can now be said about certain important seams in different coalfields that every major variation in the composition is known, and that it can be forecast for any spot within narrow limits.

The Waite Agricultural Research Institute, South Australia

THE Waite Agricultural Research Institute was established at Glen Osmond, near Adelaide, South Australia, in 1925, as a result of the late Mr. Peter Waite's gift to the University of Adelaide for the purpose of furthering the cause of education and research in agriculture and allied subjects. The total value of the bequest was estimated at £100,000.

The University Council decided that the principal objective of the Institute should be to enlarge the stock of knowledge relating to agriculture in the widest sense, and pass it on to those actively engaged in production, as farmers or pastoralists. Two chairs were established: one in agriculture and one in agricultural chemistry. Prof. A. E. V. Richardson was appointed Waite professor of agriculture and first director of the Waite Institute; Prof. J. A. Prescott was appointed Waite professor of agricultural chemistry. Since the commencement of active work early in 1925, the number of research workers stationed at the Institute has risen from five to forty, and the annual income from £8,000 to approximately £25,000, apart from a yearly grant by the Australian Commonwealth Council for Scientific and Industrial Research for the maintenance of its Division of Soils, which has its headquarters at the Waite Institute. After thirteen years of eminent service, Prof. Richardson has now resigned to occupy the position of Deputy Chief Executive Officer of the Council for Scientific and Industrial Research, and Prof. Prescott has been appointed director of the Waite Institute.

Prof. Richardson is a graduate of the University of Adelaide and was acting director of agriculture in South Australia in 1911. From 1911 until 1924 he was superintendent of agriculture for Victoria and visited the United States and Canada to report on agricultural research and education in 1918. From 1919 until 1924 he was director of the School of Agriculture in the University of Melbourne. Prof. Richardson visited South Africa, Europe, America, Japan and Java in 1926 and was a delegate to the Imperial Agricultural Research Conference at London in 1927. He was appointed a member of the Executive of the Australian Council for Scientific and Industrial Research in 1927, shortly after its inception in 1926, and was official agricultural adviser to the Australian delegation to the Imperial Conference at Ottawa in 1932. He was elected first president of the Australian Institute of Agricultural Science, which was established in 1935.

Prof. Prescott is a native of Lancashire and graduated in chemistry at the University of Manchester. In addition to post-graduate experience at Manchester, he worked at Rothamsted Experimental Station with Sir John Russell and at the University of Leipzig with Dr. Wolfgang Ostwald. From 1916 until 1923 he was chief chemist to the Royal Agricultural Society of Egypt and superintendent of field experiments at the Society's Experimental Farm at Bahtim. His work in Egypt concerned problems of soil fertility associated with Egyptian agriculture and the manuring, spacing and irrigation of wheat, maize and cotton.

In 1929, Prof. Prescott was appointed chief of the Division of Soils of the Council for Scientific and Industrial Research at the Waite Institute. His work in Australia has related chiefly to the classification and geographical distribution of soils, and his bulletin on the soils of Australia, published in 1931, has become a standard reference book throughout Australia. Prof. Prescott has travelled extensively in Australia and New Zealand and is familiar with agricultural and pastoral conditions in all the Australian States and the Northern Territory. He was federal president of the Australian Chemical Institute in 1936–37.

The association of Richardson and Prescott over the first thirteen years of the Waite Institute has proved of immense value to agricultural science in Australia.

Science News a Century Ago

The Royal Institution

The anniversary meeting of the Royal Institution was held on May 1, 1838, Benjamin Bond Cabbell in the chair. The report of the visitors showed that the income of the Institution for the year exceeded the expenditure by £140. An endowment of £1,000 in three per cent Consols had been made by Mrs. Acton, of Euston Square. Repairs and improvements to the buildings had cost £1,853. Courses of lectures then being given or soon after to commence were those on geology by John Phillips, F.R.S., professor of geology in King's College, London; those on vocal harmony—on the English opera—by Edward Taylor, Gresham professor of music; and others on electricity by Prof. Faraday and on botany by Prof. Lindley.

Henry's Investigations on Electrical Induction

"In 1838, after Henry's return from his first visit to Europe, he discovered an entirely new class of phenomena in electrical induction; and as the field was entirely his own he entered into this work with great enthusiasm. In these researches he extends greatly our knowledge of electrical induction. He first showed that an induced current may excite a second induced current in a neighboring closed conductor, and this last may induce a third current in another neighboring closed circuit and so on. These various induced currents Henry styled currents of the first, second, third, fourth, fifth, &c., orders. He shows that these currents alternate in their directions in the successive orders,—at least when these currents are induced by the discharge of a voltaic battery. He investigates the differences in the properties of these currents according as they flow through conductors formed of few convolutions of low resistance or through many convolutions of high resistance. . . . These researches into the nature and laws of the induced currents of different orders are the most finished of Henry's works and will ever be regarded as models of careful and thorough scientific work" (A. M. Mayer).

The first account of Henry's experiments was given by him in a letter read to the American Philosophical Society on May 4, 1838, entitled "A Letter on the production directly from ordinary Electricity of Currents by Induction, analogous to those obtained from Galvanism".

The Ornithological Society

At a meeting of the Ornithological Society held on May 5, 1838, J. R. Gowen being in the chair, the report of the Council was read. In this it was stated that the Commissioners of Her Majesty's Woods and Forests had caused some ponds and shallows to be made in the islands in St. James's Park, in compliance with a request made to them by the Council. Mr. Blyth then exhibited specimens of three wild British geese allied to the domestic breed, namely, the grey goose (*Anser cinereus*), the bean goose (*A. segetum*) and the white-fronted goose (*A. albifrons*), all of which are promiscuously sold in the markets under the general name of 'wild geese'. The first of them was stated to be the primitive stock of the domestic goose, and to have become of exceedingly rare occurrence in the British Islands, although it formerly bred plentifully in the Fens. Until very recently, no specimen of it existed, that he could learn of, in any of the London museums; but aged examples of the bean goose, that had the terminal *nail* of the beak white, were commonly ticketed with its name. During the severe weather of the preceding winter, thousands of bean geese were brought to market. Though it had never heretofore been known to breed when domesticated, it was stated that two females were then incubating upon one of the islands in St. James's Park.

Hancock's Steam Gig

Under the heading "Steaming Extraordinary" the *Mechanics' Magazine* of May 5, 1838, said: "Yesterday afternoon Mr. Walter Hancock, the enterprising steam carriage engineer, accompanied by two friends, rode from Stratford, and through the principal streets of the city in a steam gig. Mr. Hancock remained a considerable time with this novelty of science in front of the Guildhall, now and then guiding it adroitly around the open space. . . . Everyone seemed surprised at the ease with which Mr. Hancock threaded his way through the crowd of carts, omnibuses, cabs and other vehicles in Cheapside, Leadenhall Street and other crowded thoroughfares. The gig stopped opposite the bank for a few minutes, when the machinery was inspected by Mr. Oldham, the engineer who has fitted up all the printing apparatus of that establishment to be worked by steam."

University Events

Leeds.—Prof. Mouat Jones, of Manchester, has been appointed vice-chancellor, in succession to Sir James Baillie, who retires under the age limit. Prof. Jones, who was born in 1882, has been for seventeen years principal of the Manchester College of Technology, in addition to being dean of the Faculty of Technology of the University of Manchester.

London.—The following doctorates have been conferred: D.Sc. in zoology on Miss D. R. Crofts, a recognized teacher at King's College of Household and Social Science; D.Sc. (Engineering) on Mr. W. B. Pollard, an internal student, of the Imperial College—Royal School of Mines.

St. Andrews.—The Senatus Academicus of the University has resolved to confer the honorary degree of LL.D. on the following, among others: Prof. E. D. Adrian, Foulerton research professor of physiology and fellow of Trinity College, University of Cambridge; Prof. R. G. Collingwood, Waynflete professor of metaphysical philosophy and fellow of Magdalen College, University of Oxford; Dr. W. H. Fyfe, principal of the University of Aberdeen; Dr. A. D. Lindsay, master of Balliol College and vice-chancellor of the University of Oxford; Dr. R. T. McKenzie, emeritus professor of physical education in the University of Pennsylvania; Sir Gilbert Morgan, head of the Chemical Research Laboratory, Teddington; the Marquis of Willingdon, Viceroy and Governor General of India, 1931–36.

Societies and Academies

London

Royal Society (*Proc.*, A., 165, No. 921, April 5).

Harold Jeffreys: Significance tests when several degrees of freedom arise simultaneously.

P. A. M. Dirac: A new basis for cosmology.

P. M. S. Blackett and J. G. Wilson: The scattering of cosmic ray particles in metal plates.

R. J. Schmidt and O. A. Saunders: Motion of a fluid heated from below.

E. Glückauf and F. A. Paneth: Identification and measurement of helium formed in beryllium by γ-rays.

J. W. J. Fay, E. Glückauf and F. A. Paneth: Occurrence of helium in beryls.

M. H. L. Pryce: The neutrino theory of light.

W. C. Price and Miss D. M. Simpson: Absorption spectra of sulphur dioxide and carbon disulphide in the vacuum ultra-violet.

M. Born: A suggestion for unifying quantum theory and relativity.

D. A. Jackson and H. Kuhn: Hyperfine structure, Zeeman effect and isotope shift in the resonance lines of potassium.

Paris

Academy of Sciences, February 28 (*C.R.* 206, 633–704).

Gustave Choquet: The prolongation of homeomorphs.

Marcel Brelot: The extensions of *balayage*.

François Leja: Certain extremal rational functions.

Hubert Delange: Certain categories of series of polynomials.

Bernard Kwal: A generalization of the variational principle and of the canonical equations of Hamilton. Application to the relativistic theory of corpuscular assemblies.

Marcel Sédille: The development in series of the movement round an aeroplane wing placed in any field whatever.

Robert d'Adhémar: The theory of the gyroscopic movement of projectiles. The indeterminations.

Bernard Lyot: Observations of the solar corona and the prominences made at the Pic du Midi during 1937. 240 hours observations under the best conditions were available. 125 spectra and 13 direct photographs of the corona were taken, and 60 metres of kinematographic film showing the movements of the prominences. A preliminary discussion of the results is given.

Marcel Matricon: Application of the method of the self-consistent field to atomic nuclei.

J. Géhéniau: Spherical waves in the wave mechanics of the photon.

Jean Villey: A method for the measurement of the adiabatic compressibility of liquids.

René Lucas: Longitudinal waves of very high frequency in viscous fluids.

Maurice Dodero: The preparation by electrolysis at a high temperature of metallic phosphides, in particular, of the manganese phosphide MnP. Fused mixtures of manganese chloride, sodium metaphosphate and an alkaline chloride give manganese phosphide, MnP, capable of isolation in crystalline form and giving theoretical figures on analysis.

Mlle. Marguerite Quintin: The radius of the copper ion in solutions of the benzene-sulphonate.

Charles F. Squire: The diamagnetic anisotropy of an aromatic molecule.

Georges Simon and Jean Bouchard: The influence of a transversal magnetic field on the thermoelectric power of nickel and of various ferronickels submitted to traction.

Mme. Zina Soubarew-Chatelain and Alain Berton: The ultra-violet absorption spectra of the system MoO_3—NaOH in dilute solution. The conclusions previously drawn from the study of the variations in the electrical conductivity of solutions of molybdic acid during neutralization with alkali are confirmed by the study of the absorption spectra.

Paul Rumpf and Félix Trombe: A free radical of a new type. The paramagnetism of tritolylammenium perchlorate. If the ammenium cation exists in the monomeric form, it is true free radical, a compound with an odd number of electrons, and, according to G. N. Lewis, should be paramagnetic. Tritolylammenium perchlorate is now shown to be paramagnetic.

Mlle. Suzanne Thévenet: The influence of a given electrolyte on the viscosity of an arsenic sulphide sol at different stages of its evolution.

Augustin Boutaric: The application of the dilatometric method to the study of colloidal gels. The expansion of resinous products is related to the quantity of water present in the sample. Only thoroughly dried samples give an increase of length which is proportional to the rise of temperature.

Louis Meunier and Georges Vaissière: The polymerization of vinyl acetate.

Mlle. France Bloch: On thioacids. Discussing the two possible constitutions for thioacids, R.CS(OH) and R.CO(SH), the latter is regarded as in better agreement with experimental facts.

Const. Zenghelis and Mlle. Catherine Stathis: Catalytic hydrogenations by colloidal rhodium. Colloidal rhodium is a hydrogenation catalyst much more powerful than other precious metals. It reduces the carbonyl group easily at ordinary temperature and pressure. Aniline is reduced to ammonia and cyclohexane.

Henri Wahl: The synthesis of 9-methoxy-5-keto-5, 6, 7, 8-tetrahydrophenanthrene.

Jean Cuvillier: The discovery of lepidocyclines in the Oligocene of Egypt.

Georges Deflandre: The microplankton of the Jurassic seas preserved in the state of organic matter in the marls of Villers-sur-Mer.

Mlle. Madeleine Fourcroy: The mode of reduction of convergents.

Daniel Danielopolu and Ion Marcou: The action of adrenalin on the coronary vessels and the general circulation after the injection of diethylaminomethylbenzodioxan (883 F.).

René Guy Busnel: The influence of the food regime on the biochemistry and the biology of *Leptinotarsa decemlineata* in the fully developed insect. The action of *Solanum demissum* and of the hybrids of this plant.

Paul Wintrebert: The ring of mitogenetic induction of the amphibian egg and bipartite gastrulation.

Albert Berthelot and Mlle. Germaine Amoureux: The formation of 3-indol-acetic acid by the action of ultra-violet radiation on tryptophane. Indol-acetic acid is formed by the action of light of wave-length less than 2900 A. on very dilute solutions of tryptophane.

Albert Demolon and Antoine Dunez : Agronomic observations on the bacterial symbiosis of the Leguminosæ.

Brussels

Royal Academy (*Bull. Classe Sci.*, 23, No. 12 ; 1937).

E. De Wildeman : Abortion of the ovaries in some phanerogams (2).

A. Baudet : Cyclic homography of space of period five and on some birational transformations deducible from it.

Th. De Donder : Velocities of reaction. A general thermodynamical treatment based on the author's previous treatment of affinity.

V. Willem and R. Boolaert : Respiratory manœuvres of *Periophthalmus*.

M. G. E. Cosyns : Study of the specific primary ionization due to cosmic radiation. The particles constituting the soft and hard groups of cosmic rays are of different kinds, since the specific primary ionization is different for the two groups.

Th. De Donder : Affinity, velocity of reaction and power.

H. de Winiwater : Determination of sex.

Sydney

Royal Society of New South Wales (71, 1937).

J. A. Dulhunty : (1) Notes on the stratigraphy and physiography of the Talbragar fish-bed area. This area lying to the west of the Main Divide between Cassilis and Mudgee, exhibits a plateau at 1,700 feet in which mature topography was developed prior to the late tertiary basalt flows. The plateau falls to the west merging with the western plains, the head-quarters of the western rivers showing no late Tertiary rejuvenation. The Main Divide is almost imperceptible, being determined by an anticline which has up-warped the plateau surface. The area is occupied by an east-west trough which lagged behind during the Kosciusko Epoch. The stratigraphical sequence is complete from Mid-Kamilaroi to Lower Jurassic, exhibiting well-defined units. The chert of the fossil fish-beds forms an isolated mass occurring 30 feet above the base of the Jurassic. (2) Stratigraphy and physiography of the Goulburn River district. The area concerned is that drained by the Goulburn River. A plateau at 1,600 feet is dissected by mature valleys which post-date tertiary Alkaline Intrusives but pre-date late Tertiary Basalts. The streams show a general absence of epi-tertiary rejuvenation, and the Goulburn River occupies the axis of a tectonic trough which lagged behind during the Kosciusko Epoch. Contrasting valley types exemplify marked geological control of topographical development. Low anticlines, pitching to the north, form predominant structures which have produced undulations in the plateau surface. Kamilaroi strata are followed by Triassic Sandstone, which is separated from Lower Jurassic Sandstone by a well-marked horizon of clay shales.

H. G. Raggatt : Occurrence of glendonites in New South Wales, with notes on their mode of origin. Glendonites are believed to have formed under cold conditions on the floor of shallow and more or less isolated basins. Their alternation with calcareous concretions suggests alternation of cold (glauberite decomposition) and warm (calcium carbonate deposition) conditions. The occurrence of 'glendonites' and calcareous concretions in the Cretaceous offers confirmation of views reached from consideration of the Permian.

A. R. Penfold and J. L. Simonsen : Constitution of a phenol isolated from various Australian essential oils by Penfold and Morrison (*J. Proc. Roy. Soc. N.S.W.*, 56, 87 ; 1922). This substance, for which the name 'Bæckeol' is proposed, has melting point 103°–104°, and molecular formula $C_{13}H_{18}O_4$. It crystallizes in yellow prisms. Bæckeol contains two methoxy groups and one hydroxy group giving a monoacetyl derivative, m.p. 71°–72°.

A. Birch : Structure of origanene. (1) This paper describes the isolation of origanene in a state of approximate purity from commercial α-phellandrene, and the preparation of a number of characteristic derivatives. The evidence shows that the substance is distinct from any known terpene, and is probably bicyclic, with one double bond. Much of the published work on origanene is shown to be erroneous, many of the results obtained being probably due to the presence of impurities.

A. R. Penfold and F. R. Morrison : Essential oils of *Eucalyptus australiana* (Baker and Smith) and its physiological forms (2). Essential oils obtained from *Eucalpytus australiana* (Baker and Smith) growing in Victoria. The yield and chemical composition of the essential oils examined differed considerably from those obtained from New South Wales (*J. Roy. Soc. N.S.W.*, 49, 111 ; 1935). The principal constituents identified were l-α-phellandrene and piperitone 32–52 per cent and piperitol (the principal constituent of New South Wales trees is cineol 70 per cent). The yield of oil varied from 0·4 to 1·8 per cent, very much lower than that obtained from *E. australiana* in New South Wales, namely, 3 per cent.

G. D. Osborne : Some major geological faults north of Raymond Terrace and their relation to the structure of the Stroud–Gloucester Trough. The Williams River Fault and the Tarean Fault which break through the Upper Palæozoic rocks north of Raymond Terrace are shown to have interesting structural relations with the Stroud–Gloucester Trough, a remarkable, narrow basin which runs more or less meridionally from Gloucester southward towards Stockton. Evidence is given of the former being the older of the two faults and connected with an early phase of the Late Palæozoic diastrophism while the Tarean Fault is regarded as of epi-Newcastle age.

J. G. Churchward : Studies on physiological specialization of the organisms causing bunt in wheat and the genetics of resistance to this and certain other wheat diseases (1). Physiological specialization studies. Four wheat varieties which acted as differentials when inoculated with spores and grown in Australia and the United States separated out four physiological races of *Tilletia levis* and three of *T. tritici*. Biometrical analysis and studies of the shape, size and consistency of the bunt balls of the seven different races did not show any constant differences. Studies in the constancy of reaction, in different seasons, of bunt collections showed that some give a constant reaction while others vary within limits set by environmental conditions.

Forthcoming Events

Monday, May 2

Royal Institution, at 5.—Annual Meeting.

Royal Geographical Society, at 5.30.—Lord Moyne: "Travel Films in Kodachrome from Greenland to Rio."

Tuesday, May 3

Royal Society of Arts (Indian Section—Dominions Section), at 4.30.—Dr. R. Maclagan Gorrie: "The Problem of Soil Erosion in the Empire with Special Reference to India".

Institution of Civil Engineers, at 6.—Sir Frank Smith, F.R.S.: "Disorderly Molecules and Refrigerating Engineering" (James Forrest Lecture).

Wednesday, May 4

Imperial College of Science and Technology, at 5.30.—Prof. S. J. Truscott: "Metal Mining Enterprise" (Warrington Smyth Memorial Lecture).

Institute of Metals (at the Institution of Mechanical Engineers, Storey's Gate, S.W.1), at 8.—Prof. G. I. Taylor, F.R.S.: "Plastic Strain in Metals" (Annual May Lecture).

Thursday, May 5

Chemical Society, at 8.—Prof. J. Masson Gulland: "Nucleic Acids".

Friday, May 6

Royal Institution, at 9.—Dr. H. W. Melville: "The Nature of Chemical Reactivity".

Erratum.—Entries referring to meetings of the Institution of Civil Engineers, the Chemical Society and the British Psychological Society were inadvertently inserted in this column last week. The announcements were incorrect.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistants (grades II and III) to the War Department Chemist—The Under-Secretary of State (C.5), The War Office, Whitehall, London, S.W.1 (April 30).

Assistant (grade II, engineering—ref. *B.* 33), **Assistant** (grade II, test methods—ref. *B.* 34) in the Directorate of Technical Development, Air Ministry, Adastral House, Kingsway, W.C.2—The Secretary (S.2.D) (May 6).

Assistants (grade I—ref. 13 O), (grade II—ref. 14 O) at the Royal Aircraft Establishment, South Farnborough, Hants (May 6).

Lecturers in Biology, Physics, Mathematics, Building Science, and Chemistry in the South-West Essex Technical College and School of Art, Forest Road, Walthamstow, E.17—Mr. E. H. Finch, 263 High Street, Walthamstow, E.17 (May 7).

Chemist in the Royal Gunpowder Factory, Waltham Abbey—The Principal Clerk, Royal Gunpowder and Small Arms Factories, Enfield Lock, Middlesex (May 7).

Assistant Lecturer in Agricultural Engineering in the University of Leeds—The Registrar (May 12).

Lecturer in Mathematics in the Heriot-Watt College, Edinburgh—The Principal.

County Adviser in Horticulture in Buckinghamshire—The Agricultural Organizer, County Offices, Aylesbury.

Vice-Principal of Chadacre Agricultural Institute, Bury St. Edmunds—The Principal.

Teacher of Chemistry in the Polytechnic, Regent Street, London, W.1—The Director of Education.

Lecturer in Horticulture in the University of Reading—The Registrar.

Assistant Lecturer in Social Psychology and **Assistant Lecturer** in **Statistics** in the London School of Economics, Houghton Street, Aldwych, London, W.C.2—The Secretary.

The State and Wild Life

IN so far as science is organized knowledge, it is a reasonable assumption that it could best be attained by the organization of scientific workers for particular purposes. Such a view has received tardy recognition in Great Britain, where faith has rested upon individual effort unhampered by official allegiances (it has been nobly rewarded for its trust), and where State-controlled scientific research is still looked upon by many with a modicum of distrust. Indeed as regards the biological sciences, the influence of the State has made itself increasingly felt in directing scientific investigation only in recent years, through the creation of such bodies as the Medical Research Council, the Development Commission and the Agricultural Research Council, and there the touch-stone has been the benefit of the people through researches directly or indirectly of economic importance.

Other nations have found that State organization of biological research has been fruitful to science as well as to the people, and have developed far-reaching schemes which have become integral parts of the nation's activities. The extraordinary expansion of the United States Department of Agriculture is a case in point. Founded in 1862, the functions and work of the Department had so increased in variety and extent that, even before the Board (now Ministry) of Agriculture and Fisheries was established in England as an independent unit in 1889, it had already developed special "Divisions" each with a staff which concentrated its attention upon one particular set of problems, of chemistry, entomology, botany, forestry, pomology, animal industry, statistics. Under this policy of devolution there grew up in the U.S. Department of Agriculture an organization which has been of supreme importance for the wild life of the United States, and of which no counterpart exists in Great Britain.

On July 1, 1886, the Division of Ornithology and Mammalogy was established by law "for the promotion of economic ornithology and mammalogy, an investigation of the food habits, distributaries [? distributions] and migrations of North American birds and mammals in relation to agriculture, horticulture and forestry"[1]. It might be thought that such an investigation was limited in scope and was remote from the interests of the populace and from major problems of farming, but that has not been the experience of the United States. The work and contacts of the old Division so widened that in 1904 its place was taken by the Bureau of Biological Survey, with its own Divisions of Administration, Public Relations, Wildlife Research, Land Acquisition, Migratory Wildfowl, and Game Management, and with at the present moment a technical staff of some two hundred and fifty persons, most of whom are stationed at field headquarters in the various States.

It is pertinent to our inquiry into the relationship of the State to wild life to glance at the activities of the Biological Survey, for its functions reveal an unexpected scope and correlation of interests, along lines some of which might well be developed in Great Britain. "The Bureau of Biological Survey, the wild life service of the Federal Government, engages in research relating to the habits, economic status, and diseases of birds and other wild animals, including studies in the propagation of fur and game species; it acquires and maintains refuges for migratory birds and other forms of native fauna; conducts work in game management, under regional directors, including control of injurious species and the administration of laws for the conservation of vertebrate wild-life (except fishes). Its work is undertaken in the interest of agriculture, horticulture, stock-raising, forestry, and recreation, and to meet the natural requirements of the wild-life itself. . . . It maintains more than 100 refuges in the United States, Alaska, Hawaii and Puerto Rico for the protection of birds and of game and other mammals, conducts educational and investigational work in enforcement of laws for wildlife conservation, and develops more effective methods for the control of stock-killing wild animals, destructive rodents, and injurious birds, cooperating with State and other organizations."[2]

Although problems of economic biology in the United States differ from those in Great Britain in vastness if not in essence, the question compels attention whether some organization such as has proved so successful in America would not further investigations necessary for the understanding of the wild life of this country in its human relations.

It must not be thought that the absence of organization implies that such investigations have been neglected. The Vole Commission of 1892, the work of W. E. Collinge and others on the food of birds, the botanical surveys of W. G. Smith, A. G. Tansley, W. Davies and others, the inquiries set afoot by the British Trust for Ornithology and the Bureau of Animal Population of Oxford, and the researches upon insects and parasites of importance to farmer and forester conducted independently or with the support of the Agriculture Research Council, these and many others have added their mite to the sum of knowledge. But the fact that the majority of such researches depend upon the initiative and isolated work of individuals, or are conducted by bodies the tenure of which rests upon the insecurity of private donations, tends to make the investigations casual, incomplete, and planned for the short rather than the long view.

This unsatisfactory position could be remedied and that at no great expense to the State. In his brief address to the meeting convened by the University of London Animal Welfare Society on March 22 to discuss "Man's Relation to Nature", Prof. F. A. E. Crew properly pointed out that almost everything we need for the creation of a biological service already exists, that it should consist of men and not of masonry, and that it should make the most of biological departments in the universities, of museums, and of institutions like the Bureau of Animal Population and the British Trust for Ornithology, all of which are actually or potentially workers in the field of ecology.

It would be a mistake to develop an independent biological survey, for the essence of its investigations is that they must not be independent, but must be linked up with the efforts already being made by the State for the benefit of the people, through agriculture, forestry, the preservation of food-stuffs and materials from animal pests, and so on. The botanists have been calling for a permanent Botanical Survey[3]; the interest and variety of the problems tackled by the severely limited staff of the Bureau of Animal Population at Oxford are referred to in another place (p 822); the demand for the establishment of national parks and of Nature reserves in face of the steady encroachment of industry and human habitations upon the open spaces of the country; the possible effect upon fauna and flora; the acquisition by the State of vast areas for afforestation; these suggest some of the many problems that await the consideration of a Biological Survey. That some form of organization in these diverse and yet interrelated matters is desirable must be obvious to anyone familiar with the casual development of British economic biology.

In 1793 Pitt, with great foresight, established a Board of Agriculture with Sir John Sinclair as president, a chief object of which was to collect information respecting the agricultural conditions of each county. That Board came to an end in 1822 during a long period of agricultural depression, but the need for studying agricultural conditions, particularly in regard to wild life, still remains, although a new interpretation has been given to "agricultural conditions" by modern methods of botanical surveys and of precise analysis of animal populations in relation to climate, vegetation and other influences still unknown.

For the elucidation of all such problems of economic biology in Great Britain, we envisage a body organized, as in the United States, under the State departments dealing with agriculture, which will adopt, encourage, direct and initiate activities, botanical and zoological, bearing upon the relationship of plants and animals—the living environment—to the human population, and will keep in mind at the same time the interests of the wild life itself.

Darwin Misunderstood

Charles Darwin, the Fragmentary Man
By Geoffrey West. Pp. xiii + 351 + 8 plates. (London: George Routledge and Sons, Ltd., 1937.) 15*s.* net.

THE author has evidently spent much time and labour in writing this life of Charles Darwin and presenting it in a moderate-sized volume of 351 pages, printed in a type pleasant to read, with eight illustrations, including three of Darwin (in 1840, 1854 and 1881), one of his wife and three of his ancestors. The list of "works quoted or otherwise utilised" on pages 333–342 is an indication of the ground which was traversed in its preparation, with the fruitful results shown in the excellent choice of significant passages for quotation.

The most unfortunate feature of the book is the word "fragmentary", given prominence in the title but only fully explained at the end, where on page 329 we read—"Werner Sombart has written of 'the fragmentary man' who is the type of the capitalist executive, seeing all in acquisitive terms, subordinating the whole to the part, making the quantitative aspect the total consideration till 'all else within him dries up' and 'everything about him becomes a wilderness, all life dies, all values disappear'." The author then proceeds to his preposterous conclusion: "The resemblance of this 'fragmentary man' to Darwin is evident. The business man lives for the acquisition of wealth; the Darwinian scientist for the acquisition of knowledge—each irrespective of human consequence."

Nothing in truth could be more unlike the Darwin of whom we know so much and feel that we love, than the type described in Sombart's embittered words—the Darwin who "for nearly forty years . . . never knew one day of the health of ordinary men", and yet in the hours spared from his scientific researches, had pleasant relationships with his poorer neighbours, taking an interest in their welfare, helping to found a friendly club and acting as its treasurer for thirty years, "keeping its accounts with minute and scrupulous exactness", and explaining the position to its members on Whit-Mondays when he received them in the garden. His friend the vicar wrote of him that in all parish matters he was an active assistant and that his liberal contributions were ever ready. Darwin also acted for some years as a county magistrate, and Major Leonard Darwin informs me that it was during the drive from one of the meetings that the creative thought upon divergence of character suddenly flashed into his mind.

In his "Memories of Down House"[*], Major Darwin recalled with especial vividness a walk with his father and sister in a secluded valley beyond the "Sand Walk" at Down House, and how his father, moved by the peaceful beauty of the scene, said "that if he had to live his life over again he would make it a rule to let no day pass without reading a few lines of poetry", quietly adding that he wished he had "not let his mind go to rot so". On this Major Darwin wrote, recording his "firm conviction—a conviction which certainly was shared by all my brothers and sisters—that not only did my father thus give a decidedly erroneous impression of the changes which had taken place in his mind, but that the passages in his autobiography dealing with this subject have been constantly misunderstood and misinterpreted in the Press".

It is right to point out—and I am glad to emphasize it—that the author, again and again throughout the volume, creates an impression of Darwin which is entirely inconsistent with the "fragmentary man" described on page 329, and it is to be hoped that in any future issues the word and its definition will be omitted.

The conclusion conveyed on pages 121, 168 and 276, that Darwin was afraid of his father and treated him with an exaggerated deference, is not supported by the memories, written about 1877 or 1878, and quoted in the "Life and Letters"[†]—still less by the preceding paragraphs in which his son Francis records that "Charles Darwin had the strongest feeling of love and respect for his father's memory"; also—"his reverence for him was boundless and most touching"; and his daughter, Mrs. Lichfield, "describes him as saying with the most tender respect, 'I think my father was a little unjust to me when I was young, but afterwards I am thankful to think I became a prime favourite'." She had "a vivid recollection of the expression of happy reverie that accompanied these words, as if he were reviewing the whole relation, and the remembrance left a deep sense of peace and gratitude".

I am indebted to Major Leonard Darwin for the permission to quote the following words from a letter of November 12, 1937: "My memory of my father's attitude to his father was most certainly that he felt the strongest affection and indeed reverence for him. I myself do not remember a hint of any feeling that his father had been 'a little unjust' to him, as stated in my sister's excellent words on the situation." Also, referring to the author's words on page 168 about the purchase of a suitable property and Darwin's "diffidence towards his father in money matters", Major Darwin wrote: "At that date my father could hardly have earned enough to cover his expenses for a month, and all the capital expenditure on Down House must have come from the long and arduous labours of his father. Was it in any way surprising that he wanted to have a say in the matter ?" It should be added that Darwin's only living son enjoyed reading the book, and fully appreciates the truthful picture of the exceptionally happy home at Down House.

---

[*] "Nineteenth Century," July 1929, pp. 118–123. An attempt to explain the misunderstanding referred to in this paragraph was made by the present writer in "Darwin and the 'Origin'", London, 1909, pp. 59–66, 79–83, 256–8.

[†] Vol. 1, pp 11–20.

In addition to the serious mistakes which have been here corrected, a few minor errors were noted : "draw" for drawn (p. xii), Christ Church "College" (p. 14), Floreat "Entomologie" (71), "Maderia" (96), "Arachnidæ" (196). F. W. Hope was not the "first Professor of Zoology at Oxford" (71), but founded the chair and nominated J. O. Westwood as its first occupant. It is also to be hoped that the words in which Fitzroy's suicide is described on p. 110 will be modified.

In conclusion, I am anxious to state my belief that the author has done valuable work which will bring comfort to many readers by giving them in a book of moderate size so complete an account of the life of Charles Darwin. E. B. POULTON.

An Index to Scientific and Technical Constants

International Annual Tables of Constants and Numerical Data:

Tables Annuelles Internationales des Constantes et Données numériques. Vol. 11 (Years 1931–1934). Part 1 (Sections 1–25). Pp. xiv + 492 + xv–xxv. n.p. Index to Vols. 6–10 (Years 1923–1930). Pp. xxiv + A48 + B304. 300 francs ; £3. (Paris : Hermann et Cie. ; New York : McGraw-Hill Book Co. Inc., 1937.)

COMMENCED in 1909 as an annual supplement to existing handbooks, in course of time this work has become in itself a comprehensive encyclopædia, or, actually, more than an ordinary encyclopædia, because new volumes are continually being added to keep the information up to date. The work constitutes a classified repertory containing references to the whole of the numerical values of physical and chemical constants, since determined, in the course of scientific investigations all over the world, with critical observations.

The realization comes to every scientific worker of experience of the overwhelming mass of information published every year in thousands of transactions of societies, Government and commercial reports and independent periodicals. In a single year perhaps three quarters of a million original scientific articles and fifteen thousand books are thrown into the weltering confusion of fact and theory. True progress must be founded on a basis of existing knowledge as wide and full as can be achieved. Study of what is known is the necessary preliminary to the discovery of the unknown, and, in that study, the student needs the help of the bibliographer in increasing measure as the sources of information become greater and more diverse. During a single life-time, the physical sciences have altered nearly out of recognition. Concurrently with an unprecedented increase in the technique of accurate measurement, the volume of knowledge has increased in an almost incredible ratio. There was a time when the chemist was both expected and able to read the whole of the significant literature of his subject. Now, he is fortunate if it is possible for him to keep abreast of a particular part of it, with the aid of a voluminous bibliographical literature, produced especially for that purpose.

A comprehensive bibliography, as the means of making a thorough study of existing information, has become an indispensable preliminary to the greater task of extending the boundaries of knowledge. Yet, incredible as it would seem, the practice of bibliography is still a thankless task. He who is willing to spend his time in collecting and classifying the records and results of the work of the experimentalist is looked upon askance by those for whom he works, and the products of his labours are rejected.

In libraries provided with elaborate subject catalogues, the reader prefers to ask for a book he knows, rather than look in the catalogue, in case there may be a better or a more recent work. The more extensive a bibliography, or, the more comprehensive an information service, the less advantage is taken of it. Smaller handbooks, and information centres of limited scope, lacking both in organization and in resources, may be consulted, while comprehensive bibliographies, and bibliographical services based on the scientific study of the problems involved and an elaborate international organization, are almost unused.

If presented with a bibliography of even a hundred references to the literature of a special subject, many experimentalists are taken aback and demand instead a critical bibliography, forgetting that selection is a dangerous practice, except by omniscience, or, by the individual specialist himself.

An invaluable work, such as this before us, has been described as "ponderous volumes". Scientific workers are aware that nobody knows very much. But do we realize that we do not even know what is to be known ? The bibliographical habit needs still to be acquired. The application of the well-worn principle of trial and error would indicate very soon that a few hours or days devoted to study of the literature would be repaid tenfold in saving of time and expense. If none were permitted to enter a laboratory before having acquainted themselves with the literature of their subjects, the need for critical bibliographies would disappear.

In the present work a happy mean has been drawn between the critical and the complete. For example, under the viscosity of mercury, Erk's accepted data, obtained by experiments in glass tubes, are quoted, while only a reference is made to the paper in which Tamann and Hinüber describe the higher values they obtained in copper capillaries, although these figures may yet prove to be correct.

The "Annual Tables" were founded at the Seventh International Congress of Chemistry, held in London, on the motion of Dr. C. Marie, who became their first editor and gave so much enthusiasm to the work. The task of collecting, classifying and editing the whole of the numerical data published each year on the physical properties and physico-chemical reactions of biological, chemical, industrial and mineral substances was entrusted to a single international organization, comprising representatives of national scientific associations under the auspices of the International Union of Chemistry and the International Council of Scientific Unions. The co-operating countries comprise : Argentine, Australia, Austria, Belgium, Brazil, Canada, Chile, Czechoslovakia, Denmark, France, Germany, Great Britain, Greece, Holland, Hungary, Italy, Japan, Norway, New Zealand, Poland, Portugal, Rumania, South Africa, Spain, Sweden, Switzerland, U.S.S.R., United States of America and Yugoslavia.

In 1936, by a resolution of the Twelfth Conference of the International Union of Chemistry, the management of the Annual Tables was entrusted to a managing board, having its offices in Paris, under the chairmanship of F. Joliot, with N. Thon as editor-in-chief and P. Auger as general secretary.

The first series of Annual Tables comprises volumes 1 to 10 and the years 1910–1930, to which two indexes have been issued, for volumes 1 to 5 and 6 to 10. These indexes are classified both alphabetically by names of substances and by formulæ. The texts are in two languages, French and English. The indexes are in French, with cross-references from English, German and Italian names. The access to the data contained in the tables by means of the indexes is very easy. In fact the work is in no way more difficult to use than the larger of the proprietary handbooks. It differs from them in being more comprehensive, up to date and in having critical notes.

The second series of Annual Tables, representing the years 1931–36, is being published in two forms: (i) in two volumes, 11 and 12, comprising the data for 1931–34 and 1935–36 respectively ; and (ii) in the form of a series of "Monographs", each one containing the whole of the data appertaining to a section, or to several related sections, of the "Annual Tables". In the new series the format has been reduced from 4to to 8vo, which is certainly more convenient to handle.

The monographs vary in size from about thirty to eighty pages. They enable research workers to acquire, at reasonable cost, those sections of the tables in which they are more particularly concerned. Some of the monographs cover the periods 1931–34 and 1935–36 separately, while others include the whole period in one book. Those already issued deal with the subjects of rotatory power ; Raman effect ; radioactivity and nuclear physics ; deuterium ; dielectric constants ; free energy, heat content, entropy and activity ; heat conductance, specific heat ; elasticity, compressibility, thermal expansion, density, viscosity, surface tension ; vapour pressure, boiling points, gas laws ; Volta effect, thermo-electricity, piezo-electricity, electrical conductivity of metals, supraconductivity ; paramagnetism, diamagnetism, ferromagnetism, Hall effect ; electromotive forces, oxidation-reduction potentials ; thermochemistry ; molecular spectra and molecular structure ; Faraday effect, magnetic and electric birefringence, photo-electricity ; combustion and detonation of gases ; scattering of light, reflection and refraction ; conductance of electrolytes ; melting temperatures ; electrolytic and chemical equilibria.

The numerical data are compiled from original papers by eminent authors, selected solely on account of their competence in each particular branch of science and irrespective of nationality. The data are arranged in sections, according to subject. Each section includes a survey of definitions and fundamental concepts. The data are classified by a rational system, which enables the desired information to be located with ease. They are accompanied by indications of the methods used in their determination and critical observations, which are of the greatest value. It is claimed that the complete literature is cited on every subject. While no bibliography yet produced has attained that perfection, this one is surely very comprehensive. Another commendable feature is that articles are not ignored because their titles do not indicate them to be sources of new constants. Moreover, the printing and compact arrangement of the material are everything to be desired.

The work is the only publication which furnishes periodically new physical, chemical, physiochemical and technical data, with comments and comprehensive references to the literature. In this way it renders services which are performed by no other collection of numerical data. It is designed for all who make use of quantitative values of the properties of substances and magnitudes occurring in biological, chemical or physical phenomena, whether in pure or applied science. The work should find a place in every library that caters for such needs, where it should be given a position on the shelves in the reading room, easy of reach and near a table, and not be relegated to an inaccessible book store. The individual monographs on special subjects are indispensable to scientific workers for their everyday use.

S. C. BRADFORD.

Properties of Matter in Modern Guise

Elasticity, Plasticity and Structure of Matter
By Dr. R. Houwink. With a Chapter on the Plasticity of Crystals, by Dr. W. G. Burgers. Pp. xviii + 376. (Cambridge: At the University Press, 1937.) 21*s*. net.

THE title of this book, although a little lengthy, describes its contents with accuracy; it is essentially a study of structure approached through the phenomena of elasticity and plasticity. To give an adequate impression of the wealth of information which it contains is very difficult; perhaps the best way is to state that the substances discussed range from brass to bakers' dough. But, materials apart, the author (with the help of Dr. Burgers) has produced a remarkable treatise upon molecular physics, showing at every step how directly observable quantities like viscosity, tensile strength and so forth are connected with the type of structural unit in complex bodies, especially those of technological importance. It is the outlook of the physicist, sharply focused upon the chemist's problems. This point of view suggests something of the penetration of Kelvin, combined with a touch of Mendeléeff's power for anticipating the unknown.

The treatment is naturally to some extent synthetic, since the researches of a large number of workers are reviewed, and at fréquent intervals their compatibility or otherwise is appraised. Though the bibliography is extensive, the authors have achieved far more than a mere account of the results obtained by other people. For example, Houwink has developed a theory to account for the difference between the theoretical and observed stress-strain relationships in resin macromolecules, akin to Smekal's *Lockerstellen*. He points out that the actual number of CH_2 'bridges' present may not be equal to the number theoretically possible; again, the chance that a single molecule can be added at each active spot of a growing complex obviously diminishes as the molecule about to be added itself begins to increase in size. Many factors of this kind occur in compounds of high molecular weight, and lead to discrepancies between the 'ideal' and the 'actual', as in crystallography.

In a different connexion entirely, the appearance of this volume is particularly opportune. This is on account of the interest which is now taken by those concerned with the technical side of art in the polyvinyls, lacquers and other rheological products. For them, these pages are of great significance. Thus, a relationship is suggested—on very reasonable assumptions—between the depth and width of a brush mark (in paint), the surface tension and the yield value, in order to obtain satisfactory levelling. In this, and a number of other instances, the property of thixotropy, or the re-coherence of a substance after shaking or stirring, is of consequence, and its effects receive detailed consideration.

It is almost impossible to imagine any investigation into the properties of existing materials, or the quest for new ones, which would not be advanced by consulting this book.

F. IAN G. RAWLINS.

Wonders of the Great Barrier Reef

By T. C. Roughley. Pp. xiii+282+51 plates. (Sydney and London: Angus and Robertson, Ltd., 1936.) 15*s*.

THIS is a popular book on living animals by a writer who is interested in them as such. It undoubtedly achieves its object, which is stated in the introduction, namely, the encouragement of interest in the Great Barrier Reef and the explanation of its magnificent fauna and its flora in such a way that the lay visitor can understand what he is looking at.

Mr. Roughley's style is of a pleasing simplicity touched here and there with a subtle humour. His calm narration of startling events, such as that of the diver who had his head in a shark's mouth and escaped (p. 226), might well serve as a reproach to the impassioned journalism found in some accounts of 'foreign parts' and their animals. Chapter xvii, "Wealth from the Reef", contains a useful summary of the fisheries and the value of their products, which range from vitamins to shirt buttons. One may be allowed a little doubt as to the incessant activities of killer whales mentioned on pp. 137 and 265.

Special mention must be made of the thirty-six coloured plates. Although unfortunately one or two are out of register, the remainder are examples of photographic reproduction of a very high order. The resemblance to life achieved by some is quite startling.

Mr. Roughley must be complimented on the production of a pleasing, interesting and informative book.

Food Values:

What they Are and How to Calculate Them. By the late Margaret McKillop. Revised and brought up to date by Elsie C. Mottram. Pp. xi+155. (London: George Routledge and Sons, Ltd., 1936.) 3*s*. 6*d*. net.

ON the death of Margaret McKillop in 1936, the publishers of this book entrusted its revision to Mrs. E. C. Mottram. Considerable alteration in format, as well as the addition of new tabular matter and the modernization of the text that one of the most rapidly moving of applied sciences demands, have resulted in as useful and handy a volume as could well be required by housewife or student of social science.

The reviser has, for the most part, eschewed controversial matter, confining herself to the statement of universally accepted dietetic principles and the publication of well-established figures for the composition and analysis of food. She has, however, drawn one false conclusion from the complementary investigations of the Mellanbys and of Bruce and Callow: it is certain that bone-meal, for example, or any other food source of assimilable phosphorus would be as effective as cod-liver oil, or other form of vitamin D, in combating any rachitogenic effect of brown bread. The remarks of the author on this matter savour a little of the 'faddism' that she so rightly condemns and otherwise rigorously eschews.

A. L. B.

Projective Geometry

By Prof. Boyd Crumrine Patterson. Pp. xiii+276. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1937.) 17*s*. 6*d*. net.

PROF. CRUMRINE PATTERSON declares that his motive in writing this text-book of projective geometry was "the feeling that a more complete discussion than is usual in elementary text-books is desirable". He thinks that in this way the supplementing of the text does not occur so often and the instructor has more time to devote to discussion, analysis and solution of problems.

The method adopted is that of synthetic geometry, and the development of this method is intuitional and based on the student's earlier knowledge of the elementary geometry of the schools. As distinguished from the usual elementary treatment, there is a careful distinction made between projective and non-projective ideas, while the principle of duality is developed in some detail. Further, the proofs of some of the earlier theorems are separated into steps and that of the fundamental theorem is built up on the concept of a net of rationality as a line. The theory of the imaginary elements is also introduced in some detail and is applied to various construction problems. Finally, there is a short discussion on the general projective group transformations on a plane and some of its sub-groups, of which the most notable is, of course, the metric group. In this way, the geometry of Euclid is shown to be a special case of projective geometry. There is material enough in the book for a full year's course.

Reactions of Hydrogen with Organic Compounds over Copper-Chromium Oxide and Nickel Catalysts

By Prof. Homer Adkins. Pp. ix+178. (Madison, Wis.: University of Wisconsin Press, 1937.) 3 dollars.

THE present volume deals with the development of high-pressure hydrogenation as a tool for use in synthetic organic chemistry and more particularly with the use of black copper-chromium oxide catalyst. Prof. Homer Adkins, his staff, and research students, have made this catalyst peculiarly their own: it is particularly suitable for the hydrogenation of aldehydes and ketones to alcohols, of esters to alcohols, of amides to amines, but is notably inactive for the hydrogenation of the benzenoid nucleus, so that it may be used to hydrogenate aryl compounds without saturating the ring. The procedure for the preparation of this catalyst is given in detail, as also the details of the pressure apparatus and the method of operation.

The bulk of the book is given over to the description of the various types of reaction studied, and the conclusions reached. It is essentially a practical treatise, and therefore all the more valuable; actual figures of temperature, time, quantities taken, yields, are all given.

The reviewer's treatment of it has been to write his name in it and put it on the shelf reserved for books frequently consulted; there will be many others who will do the same.

E. F. A.

Motor Spirit from Coal

By John L. Strevens and Arthur C. Cross

THE report of the Falmouth Committee has disappointed that large section of public opinion which hoped that motor spirit might be produced from coal in sufficient quantities to render Great Britain independent of foreign supplies, either in peace or in war. On the other hand, the report recognizes the immense amount of scientific activity that is being expended on the subject, and it is therefore opportune to consider the position as it is to-day.

Apart from the three branches of the carbonizing industry—gas, coking and low temperature—all of which produce a certain amount of spirit as a by-product, there are three commercially proved systems now at work for obtaining motor spirit from coal, (*a*) hydrogenation, (*b*) coal-oil distillation and (*c*) synthesis.

Research work has brought one of the authors (J. L. S.) into intimate contact with all these processes. He was in Germany in the early days of hydrogenation developments studying the subject in conjunction with the Dye Trust and Dr. Bergius, and supervised research work in this connexion at the Kaiser Wilhelm Institute. During the past two years he has enjoyed welcome entry to the plant, where he has observed the work carried on by the Synthesis group under Dr. Martin, whose immense industry at Oberhausen may be classed as one of the wonders of the modern technical world, and he is one of the technical advisers to the British group who have developed the Cannock process of coal-oil distillation and now have plants at Tipton and Erith.

It is estimated that since Dr. Bergius's original discovery, between £20,000,000 and £30,000,000 has been spent upon hydrogenation, which in Great Britain has culminated in the plant of Imperial Chemical Industries, Ltd., at Billingham. About £10,000,000 has been spent on synthesis since its inception and approximately £1,000,000 on coal-oil distillation processes.

HYDROGENATION

Hydrogenation of coal and oil was first developed in Germany by Dr. F. Bergius and brought to Great Britain by the energy and foresight of the late Lord Melchett some twenty-five years ago. The process as operated to-day is the outcome of the pooling of all the patents and technical information acquired by international chemists and oil technologists in Great Britain, Germany and America, through the medium of International Hydrogenation Patents, Ltd. The part played by the coal industry in this development has been negligible, a fact which the industry will probably regret in time to come.

In the hydrogenation process a paste of coal and coal-oil is submitted to the intense action of hydrogen under high pressure (275 atmospheres at present at Billingham, though pressures up to 350 atmospheres are contemplated in future plants) in the presence of catalysts of the tin or molybdenum series, whereby partial liquefaction and reduction of the coal substance takes place and corresponding changes occur in the associated coal-oil. At the temperatures employed, simultaneous 'cracking' of the liquid constituents takes place and the ultimate result is the production of motor spirit and gas on one hand and an intractable residue of ash, catalyst, unconverted coal substance and heavy oil on the other.

Hydrogenation requires expensive plant of great strength and complexity to withstand the enormous pressure developed and the intensive action of the processed materials on the equipment. Once hydrogenation is effected, the rest of the plant, dealing with the hydrogenated and cracked oil products, is analogous to that of modern oil refineries.

Apart from the enormous capital cost of the plant, the complicated technique and working of the process—requiring as it does very large additional quantities of coal for power, hydrogen, steam and ancillary purposes—places a cost burden on the venture which is reflected in the very high production figure for the motor spirit obtained.

In 1936, 100,000 tons of coal were processed by hydrogenation at Billingham, and 325,000 tons of coal were utilized in the processing as well as 20,000,000 gallons of creosote and coal-oils. The production of 33,300,000 gallons of motor spirit was equivalent to 60 gallons for every ton of coal and oil utilized.

Although the progress of hydrogenation applied to bituminous coal and coal-oil mixtures has been a brilliant technical achievement, in Great Britain where the raw materials available are much more difficult to treat and much more expensive than they are in Germany, it seems unlikely that it can ever become an economic proposition, even with the excise discrimination intended for the express purpose of encouraging its development.

Any new hydrogenation plant in Great Britain would, according to the Falmouth Committee report, have to be designed to use coal only, as supplies of creosote or low-temperature tar are not available in sufficient quantities to provide for another mixed coal and tar plant, and from an economic point of view it would have to be of a minimum capacity of 150,000 tons of petrol, such plant estimated to cost £8,000,000.

The only by-products of note obtained in the hydrogenation process are the propane-butane gases, which are marketed in the form of compressed gas for household and industrial use in isolated locations; for example, Calor Gas.

COAL-OIL DISTILLATION

Coal-oil distillation is an entirely British process, organized and financed by W. B. Mitford and a group of colleagues. Eight years have been spent in bringing it to commercial completion. For the past two years much of the work has been done with the co-operation of Universal Oil Products, of Chicago, the well-known American oil cracking authority.

Coal-oil distillation *cum* cracking requires as its raw material a mixture of coal and coal-oil. In the coal-oil distillation plant of the National Coke and Oil Co. this mixture is converted into a coal-oil distillate which, because of changes brought about by its processing, is 'upgraded' into the class of naturally occurring oils amenable to the normal cracking operation. As a result this 'upgraded' distillate refines in a similar way to a medium quality petroleum, yielding a large percentage of high-grade motor spirit. Olefinic gases are also produced, from which further quantities of aviation and polymer spirits are obtainable.

This particular type of coal-oil treatment lends itself to development in widely scattered units, and is only limited by the availability of the coal-oil with which the coal needs to be pasted. If, according to a precedent already established, crude petroleum or its products are used in association with this coal-oil, then in the event of tax discrimination being exercised in favour of motor spirit produced from coal by this means, the possibilities of coal-oil distillation are limited only by the availability of such oils.

Why, it may be asked, is the oil from coal under this process changed into the character of a natural petroleum? This phenomenon has been discussed in scientific circles in the United States, Germany and Great Britain. The probable explanation is that the primary oil constituents of the coal have been 'soaked out' by the associated coal-oil and the deleterious material removed in the processing treatment. The coal-oil distillate 'upgraded' stock yields 43 per cent motor spirit when treated in a modern cracking plant. Thus by this process there has been obtained from coal and coal products (creosote, etc.) an oil stock that is, so far as motor spirit production is concerned, akin or similar to many natural crude petroleums. For the treatment of our huge supplies of suitable coal this development should prove eminently successful.

A standard unit for a process of this description consists of a coal-oil treatment plant having a daily throughput of 400 tons of 'paste' (50 per cent coal and 50 per cent oil), and a refinery with a capacity of 1,000 barrels of dephenolated 'upgraded' oil stock per day.

On the basis of a yield of 78 gallons of motor spirit per ton of stock treated, such a unit would produce 5,000,000 gallons of high octane product per annum. This yield is guaranteed by Universal Oil Products after testing the stock produced.

No account of coal oil distillation would be complete without reference to the smokeless fuel residuum, phenols, and rich gaseous by-products derived from the process.

The smokeless fuel is, on test, superior in every way to that obtained by ordinary dry methods of coal treatment. Apparently a proportion of oil absorbed in the coke residue imparts valuable properties which are reflected in its higher calorific value, complete combustibility, intense reactivity and high radiant heat value.

The phenols are equal to those produced from high-temperature coal tar, whilst the gas is rich in those higher hydrocarbons, making it particularly suitable for industrial metallurgical operations and as a motor transport fuel when compressed into portable cylinders.

SYNTHESIS

Synthesis, or coal-gas treatment, is essentially a German development which has taken fifteen years to come to commercial practicability. It is based on experiments conducted over a number of years by Prof. F. Fischer and Dr. Tropsch, of the Kaiser Wilhelm Institute. This process forms part of the Four-Year-Plan now being carried out in Germany.

The synthetic processes are based on the well-known fact that oxide of carbon can be hydrogenated *at normal pressures* in the presence of catalysts of the eighth group of the periodic classification of elements to form a mixture of gaseous, liquid and solid hydrocarbons analogous to crude petroleum. The initial gases can be prepared in various ways from all types of carbonaceous material such as coal and coke, or from oil and gaseous hydrocarbons. Once a mixture of carbon monoxide and hydrogen in predetermined quantities (usually one part carbon monoxide to two parts of hydrogen) of the right degree of purity is available, the production of 'synthetic oil' is an open field.

One form of this development which has been brought to a state of almost technical perfection on an extensive commercial scale is operating in Germany under the name of the "Fischer" process, but only small-scale experiments along similar lines have so far been carried out in Great Britain.

The synthetic products of the Fischer process consist of 9–10 per cent of gaseous hydrocarbons, 60 per cent 'straight' open-chain paraffinic motor spirit, 28 per cent high-grade Diesel oil fraction and 2–3 per cent wax, but slight modification in processing influences these proportions greatly.

COST PER GALLON

No attempt has been made in the Falmouth Committee report to compare the normal costs per gallon of producing motor spirit by the various processes examined. A fair estimate of the cost for the motor spirit produced by hydrogenation would be approximately 11*d.* per gallon, remembering that in all new plants it is difficult to assess the amortization figure. The octane rating of this spirit is 70 plus.

The outstanding feature of coal-oil distillation *cum* cracking is that from one ton of coal and one ton of coal-oil make-up there is produced 78 gallons of motor spirit. The approximate cost of this spirit, allowing average price for all other products, is 7·2*d.* per gallon, and the octane rating is 73–74.

A feature of synthesis is that 5½ tons of coal are required for the production of one ton of synthetic oil product. The yield of finished motor spirit is 40–45 gallons per ton of coal, and the cost may be placed at between 10½*d.* and 1*s.* 1½*d.* per imperial gallon. This range in the estimated price is advisable owing to the fact that in Germany the synthetic industry is very closely associated with the benzole industry and it is not easy to determine the net cost of the synthetic motor spirit. The best octane rating of this spirit is 62.

LIMITATIONS OF THE PROCESSES

Each of the processes considered has its peculiar limitations which must be borne in mind in surveying the economic position.

In the case of hydrogenation, the capital cost is enormous. There are definite limitations to the percentage of coal in the coal-oil paste which it is advisable to treat. There are difficulties in the treatment of the residue and the recovery of the catalyst. It may be that the success of the process will ultimately rest upon the finding of an economic method of separating the catalyst from the residue and the means of handling it.

With coal-oil distillation *cum* cracking an important limitation lies in the supplies of creosote or similar coal-oil products at economic prices. In a state of national necessity the major portion of coal-oil produced would doubtless be made available for the preparation of home-produced motor spirit. If in the interests of the coal industry it were felt wise to make available, unhindered by tax, imported natural petroleum, the field for both hydrogenation and coal-oil distillation would be unlimited.

So far as synthesis is concerned, the motor spirit produced is of low octane rating. It is obvious that there would always have to be available 'upgrading' material at an economic price, such as benzole, alcohol, tetra-ethyl lead, iso-octane, etc. The synthetic process may always be limited by the high cost and availability of the necessary catalyst.

ADVANTAGES

The synthetic process is the only one so far developed which produces from coal a Diesel oil of first quality.

The coal-oil distillation process is the only one of the three under review which produces economically a large quantity of smokeless fuel of high radiant heat value and complete combustibility.

The valuable phenols so essential to the nation's needs in times of peace and war can only be obtained from coal distillation processes and the tar industry, and not from hydrogenation or synthesis.

Plants of the Sand Dune and why they Grow There*

By Prof. E. J. Salisbury, F.R.S.

THE vegetation of a sand dune is unique not only because of the rapidity of the changes that it exhibits but also because, from the manner of dune development, the phases present an arrangement in space corresponding to their sequence in time, so that the plant succession can be ascertained with certainty.

The embryo dune frequently begins around seedlings of either *Agropyron junceum* or *Ammophila arenaria*. Both are characterized by an important reaction to burial by sand, namely, that they are stimulated to grow through to the new surface. The projecting leaves by reducing wind movement not only shelter the surface from erosion but also bring about further deposition. *Agropyron junceum* can grow normally in 1·5 per cent of salt and tolerate considerable periods of inundation by sea-water, whereas the marram grass cannot. But *Agropyron*, owing to its drooping habit, as contrasted with the erect habit of marram grass, is not so efficient a collector of sand and has much less capacity for vertical growth. Hence it only forms low dunes at low levels on the beach, whereas the marram grass is the successful pioneer at greater elevations and indeed is always the dominant species on English dunes in their early stages. It not infrequently brings about a rise of more than a foot a year in height, whilst its lateral spread may exceed 36 sq. ft. a year. Other grasses that play a part in the early stages are *Elymus arenarius* and *Festuca arenaria*. All these grasses spread by means of rhizomes from which at intervals tufts of leaves are given off above and roots below.

---

* From a Friday evening discourse delivered at the Royal Institution on February 4.

Measurements of a number of plants over a period of years indicates that both the pioneers *Agropyron junceum* and *Ammophila arenaria* have a remarkable capacity for rapid spread in their early stages of growth, which must render them peculiarly fitted for the occupation of a mobile habitat. The average areas occupied by twenty plants of *A. junceum* in the first few years of their development were : 1 sq.ft. ; 5·7 sq. ft. ; 18·4 sq. ft. ; and 37·4 sq. ft. ; the maximum annual increment, amounting to about 600 per cent, being exhibited during the second year's growth. The rate of radial extension gradually rises during the first three years to about a foot a year. The marram grass, though spreading at a slightly slower rate, namely, about 0·7 ft. per year, exhibits a maximum radial extension in the second year of growth which, in the plants studied, amounted to an average increase of area of no less than seventeen times. *Agropyron junceum*, through its greater toleration of sea water, can not only colonize at lower levels but also tends to occupy sand that is normally moister and hence firmer than that higher up where the marram grass is the dominant pioneer. The remarkable initial capacity for rapid spread of the latter may therefore be of some significance in its more mobile station.

The sand dune, though it may receive as much precipitation in the form of rain and dew as an inland situation, can be aptly described as an edaphic desert—a desert that is due, not to climatic but to soil conditions, since the coarse texture and very low organic content render sand a very poor retainer of water.

Data that I have obtained respecting the actual natural water content of dunes from a number of different localities around our coasts, shows that even after heavy rainfall the supply at the surface of a young dune rarely exceeds 10 per cent. Normally, however, the amount of water available to the plant is less than 4 per cent and frequently much less. For example, if there is a spell of dry, cold, windy weather the amount of water in the first two inches may fall to below 1 per cent, of which only a small part is available to the plant. On the other hand, the water content at six inches is normally between 4 and 5 per cent, and in warm sunny weather, which tends to promote rapid water-loss from the plant, there is an important compensatory phenomenon which plays a fundamental part in maintaining a fairly constant, if low, supply of water for these dune species. Owing to the large size of the sand particles and the dryness of the surface grains, these constitute a very bad conductor of heat. Hence the heat of the sun received by the superficial layers is not conducted downwards, as in normally moist soil, but results in very high surface temperatures being attained.

Excessive heating of the surface grains raises the temperature of the air in the interstices and the rising convection currents draw in warm moist air, from over the sea and adjacent tidal lands, into the interior of the dune. Here the moisture-laden air impinges upon the cooler sand grains and brings about a phenomenon known as internal dew-formation. Just because this is most pronounced in conditions of prolonged sunshine, internal dew-formation takes a most important role in stabilizing the moisture supply at a time when it might be expected to attain a minimum.

Compared with the shortage of water, the other factors adverse to plant growth, such as the mobility of the substratum, the changing level and the poverty in nutrients, are less inimical to plant life. Further, it must be emphasized that the high temperature attained by dune surfaces accentuates the effect of the small water content. We are not surprised that the number of these pioneer species is very few, but rather that these few can withstand the rigours of the habitat and even flourish despite them. In what way are these pioneer species equipped so that they can endure these very specialized conditions ?

Owing to their extensive rhizomes, the risks consequent upon the mobile habitat are minimized. Further, a single plant thus exploits by its roots a very large volume of sand. Penetration of the sand by the rhizomes is facilitated by the structure of their apices, which are woody with a sharp point well suited for piercing the sand and capable of withstanding the inevitable abrasion. But the feature which more than any other fits these pioneers for growth on a dune is that they all possess leaves which automatically flatten out when their water content is high and curl into a cylinder when their water supply is low. On a dry windy day the leaves of the grasses appear like narrow tubes split along one side, and this split widens or narrows in exact relation to the increase or diminution of the ratio between water absorption and water loss. This feature is of most importance when conditions are most extreme, but some idea of the efficiency of the mechanism can be gained from the fact that experiments with *Elymus* have shown that even under slight air movement the rolled leaves transpire only about a tenth of the water lost by the leaves when flat.

The only plants of these early phases which have not such automatic transpiration checks are those of the drift line on the dune face. These species are able to survive during periods of shortage by storing up copious internal water reserves, the presence of which renders the leaves succulent. The two most frequent are the sea rocket (*Cakile maritima*) and the prickly saltwort (*Salsola kali*). Both are very tolerant of sea water.

By the activity of the pioneer species, three main changes result. The embryo dunes rise in height, extend laterally and the hummocks coalesce to form a definite ridge, which may attain to heights of from sixty to one hundred feet in Great Britain. The decaying leaves, rhizomes and roots add organic material to the sand mass. Thus the dune becomes not only less mobile but also its capacity to retain the water that either falls upon its surface or condenses within is continually being augmented. So the extreme conditions become ameliorated and sooner or later, on advancing shores, the establishment of new dune ridges seawards of those already formed gives some protection both from sand removal and from rapid accretion.

The less specialized conditions which thus ensue are marked by the advent of other perennial species only slightly less specialized than the grasses. Of these the most characteristic are the sand sedge (*Carex arenaria*), the convolvulus (*Convolvulus soldanella*), sea spurge (*Euphorbia paralias*), sea holly (*Eryngium maritimum*) and rest harrow (*Ononis arvensis*). The sand sedge is remarkable for the rapidity of its growth and the extent of its rhizomes. From the parent plant the rhizomes radiate out like the spokes of a gigantic wheel and grow horizontally a few inches below the surface of the sand, sending up tufts of leaves at intervals of about four to six inches throughout their length. With the passage of time some of these tufts form the centres of origin of further radiating rhizomes, thus in a few years the sand is occupied by a sort of network bearing tussocks that constitute an efficient wind-break so that this species is an important stabilizer. The sea spurge and sea holly, not being rhizomatous species, have little capacity for lateral growth and so are more susceptible to sand removal, but they both exhibit rapid response, by new growth, to burial. In common with the other dune perennials, they meet the low water supply by means of a deeply penetrating and extensive root system (in the sea holly this may penetrate 2·7 m.); also they both possess leaves with a thick protective cuticle.

Up to this stage of dune development, a considerable area of bare sand is still obvious between the tufted growths. This implies great vulnerability to high winds and consequent risk of rapid erosion or accretion, thus precluding the development of species incapable of rapid growth. However, with the passage of usually about half a century, conditions have become sufficiently stabilized and the rate of accretion sufficiently diminished to permit the growth of dune annuals. These dune annuals are all characterized by germinating in the autumn, and passing through their life-history during the winter months, flowering in the spring and perishing with the surface drought of summer. They evade the adverse period in the seed state. The capacity of the dune annual to grow during the colder months of the year is enhanced by the warmth of the surface sand in sunshine. This brings about a rise in temperature of the air just above the sand. As a consequence, the leaves of these annuals are sufficiently warm to carry on active photosynthesis when this would be quite impossible for plants on other soils with a more normal capacity for heat conduction. Readings taken on the Norfolk dunes in April indicate that the temperature immediately surrounding the dune annuals may frequently be 10°–15° C. higher than the air generally.

All these dune annuals afford a striking contrast to the dune perennial by reason of their shallow roots, which only penetrate to an average depth of about four centimetres. They are enabled to flourish partly because of the frequent rains and high average humidity of the winter months, but even more because by the time of their arrival the pioneer species have added to the surface sand sufficient organic matter to augment appreciably the water-retaining capacity. Moreover, all these dune annuals are rosette species with foliage close to the ground, thus occupying the most humid layers of the air and a level least exposed to wind action.

It has been possible to obtain data as to the water loss by various species when in sand of a normal water content. Such data show that a plant of *Cerastium semidecandrum* may, on a sunny day, lose water at the rate of more than two grams per 100 sq. cm. of surface per hour. If we allow for the normal volume of soil exploited and the average water content, this rate of loss involves complete removable of the available water supply within about a day. Since this species will survive a period of more than a week without rain, it is evident that it must depend on internal dew formation and upon the movement of water from beyond the immediate vicinity of the root system. The maintenance of such a flow requires some motive force, but this is supplied by the osmotic suction of the roots, which in various dune plants has been found to range from 9 to 20 atmospheres, or a force of from about 130 lb. to 290 lb. per sq. inch. Much higher osmotic pressures equivalent to 630 lb. to the sq. inch have been observed in dune plants of Algeria and California.

By their carpeting of the dune surface during the season of frequent high winds, the annuals materially diminish the risk of surface erosion, and they in turn add further to the humus in the soil. Their protective action, which ceases when they shrivel in summer, is augmented by certain mosses, of which *Tortula ruraliformis* is the most important, which endure periods of severe drought quite unharmed.

The prevalence of lichens also on the more advanced stages of stabilized dunes has given rise to the name of 'grey dune' in contrast to the younger 'yellow dune'. The vegetation carpet is quite efficient so long as unbreached by the tracks of man or the activities of the ubiquitous rabbit The latter is often the source of exposure that permits wind entry and erosion, leading to a so-called 'blow-out', that either results in complete removal or initiates a 'secondary succession'.

A striking feature of earlier dune phases is the frequency of comminuted shell fragments among the sand grains. The proportion of calcium carbonate thus furnished varies greatly from one dune system to another. Some in Dorset contain practically none, and heather appears quite early in the dune succession, whilst other dunes contain a high proportion (up to 17 per cent at Bundoran in Ireland). In Portuguese dune samples from Comporta I found up to 27 per cent $CaCO_3$ in the young dunes and 0·2–0·4 per cent in the leached sands of the old. According to J. A. Van Steijn, the dunes of Holland show a similar range to those of Britain; he gives 0–18 per cent as the range of lime content. Where the calcium content is high, for example Tenby dunes, there are usually a number of calcicole species.

Before passing to the final stages of dune development, we may pause to consider a feature that will in most dune systems have already appeared. We shall note that dunes tend to develop as ridges parallel to one another. This usually intermittent formation is partly due to the presence of the main dune ridge, which by upward deflection of the on-shore wind produces a relatively calm condition at the ground-level immediately in front, so that embryo dunes starting here would exhibit little accretion. Still more, perhaps, it is due to the fact that the sloping sand in front of the ridge has the effect of pushing the main drift line farther out, and it is usually in relation to the buried drift that the new dunes begin to form. Thus the marram grass seedlings which arise along the drift line exhibit rapid growth and rapid accretion, and so form a young dune ridge separated from the pre-existing one by an interval. The parallel ridges often rest on a relatively impermeable substratum, and the water, of which the dune ridges are the catchment area, drains into the intervening hollows and sometimes forms what are known as 'dune slacks'. They naturally exhibit a marsh and aquatic vegetation which is beyond the scope of our present treatment, but there are a few special features to which attention must be directed. These slacks are the especial home of the creeping willow (*Salix repens*), which by its mode of growth and extensive root system (it will form roots more than 25 ft. in length) is able to spread into the dunes proper and can even grow successfully in mobile sand, but its apparent role as a pioneer is probably illusory, despite all statements to the contrary.

Into these slacks the drainage water from the dune ridges brings the nutrients, particularly the calcium salts leached from above, and to this fact we must, I think, attribute the presence of species that we more particularly associate with dry chalky soil. Such plants as *Chlora perfoliata*, *Linum catharticum*, *Gentiana campestris*, even *Carlina vulgaris* and the lady's tresses (*Spiranthes autumnalis*) are to be found growing even in free water. In such a 'slack' the soil contained 3·0–3·7 per cent calcium carbonate and the reaction was *p*H 7·5. The dune ridges on either side of the 'slack' contained about 0·3 per cent of carbonates and were appreciably acid (*p*H 6·8).

The dune slacks are the especial home of the bog pimpernel (*Anagallis tenella*) and the brookweed (*Samolus valerandi*). Here too in the southwest grows the giant spiked rush (*Juncus acutus*), whilst in similar situations in the Southport dunes occurs a remarkable habitat form of the grass of Parnassus (*Parnassia palustris* f. *condensata*) and also a sand form of the beautiful *Pyrola rotundifolia*. There are also certain liverworts which are peculiar to this situation, notably the rare *Petalophyllum Ralfsii*, which exhibits perennation by means of tubers. The shallower slacks often become dry during the summer months and here occur remarkable depauperate forms of many species.

Throughout the dune development, certain continuous changes have been going on apart from the diminishing mobility and increasing water-retaining capacity to which I have especially directed attention. These are the progressive leaching out of the soil carbonates and the augmentation of the acid products of organic decay, and so it is that we find that the prevailing alkaline condition of the young dune passes gradually into an acid state of the old. In the regions of higher rainfall, peat accumulation leads to the development of heather moor as on the old dunes of the Culbin Sands on the Moray Firth.

The progressive changes in the character of the dune soil with the passage of time are shown by the two series of data summarized below. These show the increasing acidity (diminishing pH value), increasing organic content, and decreasing content of calcium carbonate, in two dune systems. One (Blakeney) with an initially low carbonate content, and the other (Southport) in which the initial carbonate content is comparatively high.

SOUTHPORT DUNE SYSTEM

Approximate age of dunes in years	$CaCO_3$ %	Organic content %	Reaction
2	6·3	0·53	8 2
6	4·15	0·33	8·2
14	3 17	0 68	8·15
25–55	2·6	0 74	7·8
100	1·14	4 0	7·2
200–280	0·28	5 9	6·4
BLAKENEY POINT DUNE SYSTEM			
5	0·42	0·36	7·2
80	0 34	0·5	7 0
160	0 03	0·86	6 9
235	0 01	1·15	6·4
340	0·01	2·7	6·2

Whereas the young yellow dunes only possess a flora of about ten species, the later yellow dunes can support between fifty and sixty different kinds of flowering plants, and the comparatively stable grey dunes have a flora of more than a hundred, exclusive of those confined to the 'slacks'.

The specialization imposed by the physical attributes of the habitat itself have been permanently modified; but the final occupants may themselves create specialized physical conditions which once more restrict the supportive capacity of the habitat.

Landscape at the Royal Academy

IN considering pictures from the point of view of science, one is glad to subscribe to what appears to be Ruskin's central doctrine, which may be put thus: a creative artist in portraying natural subjects, whether figure or landscape, should base his work, except in so far as it is meant to be symbolic, on a scientific realism expressing the love of Nature, and should carefully restrict the selection of particular effects to the suppression of others where this is rendered necessary by the limitations of the medium.

There can be no question but that both scientific realism and the love of Nature are apparent in the pure landscape work which has figured so prominently in British art since the time of Constable, and that the annual exhibitions of the Royal Academy reflect this tradition The 1938 exhibition has the usual large proportion of landscapes amid figures, portraits, historical scenes and coronation pageantry, and in this short notice attention may be directed to a few of the landscape canvases, leaving out of account the quite strong representation in water-colour.

Mr. Sydney Lee's "Lulworth Cove" (274) well suggests location in the midst of a stretch of the Dorset coast-line, as high, rugged and fierce as any in England. The rock-contortions about the cove should please geologists, but the general alignment of the cove in relation to the open sea will certainly force attention on the laws of perspective.

Another pleasing Dorset scene is that in a small picture by Major C. E. Phillips, secretary of the Royal Institution, entitled "On the Purbeck Hills" (76). The general conformation of the land, as well as the line of stone walls in the background, would place this scene, not in the range of chalk downs that sweep round by Corfe Castle, but in the limestone ridge the upturned edge of which forms the splendid high coast between Swanage Bay and St. Aldhelm's Head.

In "Bibury Bridge" (26), Miss Kathleen M. Pearson presents a typical Cotswold scene: the delightful oolite stone, ever dominant, never out of harmony with other elements, the backing of stately elms gloriously grouped, and the foreground touch of animation given to the precincts of the village by two lads with a dog. The "Sutherland" (314) of Mr. Borlase Smart shows an inlet of the sea overlooked by mountains, but the whole power of the picture to the present writer lies in its suggestion of the wild tract of the Northern Highlands that lies behind the scene depicted. The grand simplicity of the title hints, indeed, that this is precisely the reaction the artist intends. "On the Moors, Skye" (760), by Mr. Arthur T. Nowell, is a skilful rendering of the beautiful lighting effects so typical of showery weather in the wild hills of the Western Highlands.

The background of Mr. Walter Goodin's "The River, Beverley" (429) is occupied by intensely black thunder-cloud, and the foreground, beneath brighter sky, by a great poplar obviously waving and rustling in the wind against which the storm is coming up—a most realistic example of landscape meteorology. Dazzling lightning, with the branching structure revealed in photographs, leaps across the mountains in Mr. Frederick C. Tilney's "Nothing Matters to a Machine" (571), in which a motor-car is seen speeding through a rugged defile. If it be objected that the landscape artist should paint what he sees of lightning, not what he knows about it, one can retort that some artists have extraordinary sight for lightning structure, as evidenced by Turner, in whose time photography was in its infancy.

There are various snow scenes from different parts, but that exhibited in J McIntosh Patrick's "An Exmoor Farm" (313) is peculiarly charming by reason of the delicate contrast of the expanse of misty glaucous sea, very true to type, seen away in the distance. "The Bow in the Clouds" (192) of Victor Weingott, wherein a rainbow with secondary arc appears over a number of well-portrayed human figures, may be mentioned because it is very unusual in pictures to find the luminosity of the sky so accurately graded as between the inside of the primary, and outside of the secondary, bow.

The convolutions, rifts and gulfs in the white surface of a magnificent chain of cumulo-nimbus cloud are rendered with some success in Mr. James Bateman's "Farm Yard" (227), but it may be questioned whether the lower mass of cloud to the right of the picture is in the correct plane. Lawn and trees in a midsummer setting of deep blue sky and small radiant cumulus clouds are given in Mr. Algernon Newton's "Wimpole Hall, Cambridgeshire" (407), and it is interesting to note the same type of study by the same artist on foreign soil in "The Villa Starhemberg, Bad-Ischl, Austria" (144). Lawn and trees are in brilliant sunlight in front of the villa, but stormy-looking clouds are beginning to rear up over the Alps behind, and very intense shadow is being cast by the mountain shoulder on the left—an impressive illustration, to be sure, of Ruskin's "mountain gloom". The fault of this telling picture is the uniform dull brown colour in which the foliage of the trees in front and the mountain slopes behind are painted.

Landscape art makes a unique contribution, not so well appreciated as it ought to be, to meteorological science, in fixing just those subtle scenic aspects of atmosphere and weather, in short, those imponderable elements in climate, that not only produce profound psychological reactions but also inevitably leave their stamp on the development of art and literature.

L. C. W. BONACINA

Obituary Notices

Mr. T. H. D. La Touche

WITH the death on March 30 at the age of eighty-two years of Thomas Henry Digges La Touche, the Geological Survey of India has lost its oldest member. Educated at Shrewsbury and St. John's College, Cambridge, that breeding-place of geologists, he was appointed to the Geological Survey of India in 1881, promoted superintendent in 1894 and acted as director in 1906 and 1909, retiring in 1910.

During his service of almost thirty years, La Touche acquired an exceptionally wide acquaintance with all aspects of Indian geological problems, scientific and economic. His work extended from Baluchistan in the west to the Burma-Chinese frontier in the east, and included investigations of the coal-measures of Assam, Kashmir and the Northern Shan States; the sapphires of Kashmir; oil in Baluchistan; the great silver-lead-zinc deposits of Bawdwin in conjunction with Dr. Coggin Brown; and the Lonar Lake with Dr. Christie. He also investigated the geology of western Rajputana, and his account includes a detailed petrological description of the igneous rocks of that region.

La Touche's greatest work, and the one which he himself looked back upon with legitimate pride, was the survey of the Northern Shan States of Burma. This was undertaken during the later years of his service, and from time to time he had the assistance of other members of the Department. The results, embodied in *Memoirs, Geological Survey of India*, vol. 39, part 2, with descriptions of the fossils by various specialists in the *Palaeontologia Indica*, opened up an entirely new chapter in the geological history of Burma and embodied "many valuable discoveries bearing on the question of the extension of Asian Zoo-geographical provinces during the Palaeozoic era"

In addition to his official publications, La Touche found time to edit for the Asiatic Society of Bengal, of which he was president, the journals of Major James Rennell, the first Surveyor General. He was also a superb amateur photographer, and his ingenious adaptation of the Walker balance to the rapid determination of the specific gravity of rock specimens is well known to all his colleagues.

After his retirement, La Touche's services were not lost to India. In 1914 he published "A Bibliography of Indian Geology and Physical Geography with an Annotated Index of Minerals of Economic

Value". This was followed by the index to genera and species described in the *Palaeontologia Indica*; an index to the *Records*; and finally, the last proof reaching him just before his death, the index to the *Memoirs*. This series of publications is of inestimable value to all interested in Indian geology, and the Survey can congratulate itself on being the best documented service in existence. In addition, he prepared for the Geological Society a list of literature added to its library during the War period.

La Touche's interest in geology was very wide, and his knowledge was always at the disposal of any inquirer. His work is characterized by a minute attention to detail, a scrupulous accuracy of observation, and a strict regard for truth. He received no recognition from official nor from non-official bodies, but he has left behind him a record of a lifetime's work which can rarely have been equalled, and a lasting monument to his industry, the more surprising as he suffered throughout his career from greatly impaired sight.

La Touche married Miss Handy, an Irish lady of great charm, and had five children, two boys and three girls. One son was killed in the War while the other carries on the family tradition of service in the East as a member of the Burma Forest Service. To his widow and the surviving members of the family the sympathy of all his old colleagues is respectfully tendered.

G. H. TIPPER.

Prof. John Taylor

BY the death of Prof. John Taylor on April 11, Irish engineering has lost one of its best known figures. Born near Gask, Perthshire, in 1865, he received his early engineering training in Glasgow at the Cowlairs Locomotive Works of the late North British Railway. In 1888 he won a Whitworth exhibition from the Anderson Technical College, Glasgow, and a Royal scholarship tenable at the Royal College of Science for Ireland, and proceeded to Dublin. He took the associateship of that College in 1891, after which he received a junior appointment on the staff and in 1902 became lecturer in engineering. In the University of Dublin, in 1903, he gained the large gold medal and senior moderatorship in experimental science. In 1929, a few years after the Royal College of Science for Ireland had been taken over by University College, Dublin, he was appointed professor of mechanical engineering in the National University of Ireland. About two years ago he received the degree of D.Sc. (*honoris causa*) of the National University.

Prof. Taylor did much work on the causes behind the failure of materials, and his technical advice was frequently sought by Irish public bodies. He conducted tests necessary for the planning of the dam in connexion with the proposed hydro-electric undertaking of the Liffey scheme at Poulaphouca, and carried out experiments with fish passes for the Shannon hydro-electric scheme. In recent years he devoted a considerable amount of his time to an investigation into the efficiency of turf burning appliances, a study which he undertook at the request of the Industrial Research Council of Eire, of which he was a member. His work in this connexion has already resulted in efficient domestic cooking ranges, suitable for the Irish turf consumer, being placed on the market.

In his teaching work, Prof. Taylor was noted for his thoroughness and enthusiasm. During his long career as a teacher a very large number of students passed through his hands, by all of whom he will be remembered as a man of the highest character with the most conscientious devotion to duty.

Mr. F. J. Gould

MR. F. J. GOULD, who died on April 6, was one of the most devoted and persistent workers in the cause of humanism and world peace. He was born in 1855 and kept up his activities in writing and speaking for his faith to within a few weeks of his death. He himself published annually an account of what he had done in the way of writing, editing and above all giving moral lessons to the young, and this amazing record moved large numbers of persons to subscribe to a sustentation fund which had become necessary for him when his uneasy relations with the London School Board came to an end in his early years. He had been an assistant master in East End elementary schools, and the kind of religious teaching which was required of teachers in those days was much more hotly debated than it is now in less dogmatic days. But Gould's ideal was never in doubt and never changed. He advocated from first to last the teaching of a sympathetic outline of the chief faiths of the world and the education of the young mainly by moral and historical lessons based on the admirable features of the past.

Gould had in early years been deeply influenced by the Englishmen, who, like Frederic Harrison, owed their spiritual direction to Auguste Comte. To this he added a strong socialist leaning and a faithful association for more than fifty years with those who defended the claims of free thought in the pages of the *Literary Guide* and elsewhere. His apostolic journeys took him over the greater part of the United States as well as India, while for many years he laboured as secretary for the International Congress of Moral Education. He acted in this capacity in London, The Hague, Geneva, Rome, Paris and Cracow. Before the Hitler régime he had been co-operating with liberal-minded Germans on a plan for an improved and more international method of teaching history. This perhaps was his deepest and most abiding motive.

Gould's mind was a rare compound of peaceful and loving appreciation of men and opinions of every type, combined with an unbending and untiring tenacity in promoting the type of thought to which as a young man of just over twenty he had given his allegiance. It may be safely predicted that one day—and not very far distant—his name and work will be more loudly acclaimed and recognized than they have been in the first days following his demise.

F. S. MARVIN.

News and Views

Scientific Associations of the Royal Academy

Among the portraits of men of science and others known in scientific circles in this year's Royal Academy Exhibition, that of Sir Frederick Gowland Hopkins (196), by Meredith Frampton, a reproduction of which appears on this page, has led to considerable discussion as to extent to which a portrait should dominate its background. Other portraits to which reference may be made in these columns are: Sir David Milne-Watson, Bt., governor of the Gas Light and Coke Company (166), by Harold Knight; Sir Joseph Barcroft (263), by R. G. Eves; Lord Wakefield (371), by I. M. Cohen; Sir Frederick Moore (600), by Dermod O'Brien; and Havelock Ellis (1094), by Robin Guthrie. There is a sculptured head of Sir Michael Sadler (1571), by Loris Rey; and a head of Kelvin (1564), by Norman Tyrrell. Among the medals are that of the Institute of Metals (1471), by Harold Stabler; and the Hele Shaw Medal of the Institution of Mechanical Engineers (1485), by H. Paget. The architectural drawings include the National Institute for Medical Research at Mill Hill (1260), by Maxwell Ayrton; Beaumont Street extension of the Ashmolean Museum, Oxford (1277), by Stanley Hall and Easton and Robertson; the completed scheme of the house of the British Medical Association (1317), by Douglas and J. D. Wood; and the Palaces of Engineering (1360) and Industry (1366) of the Empire Exhibition, Scotland, 1938, by Thomas S. Tait.

Dr. W. F. K. Wynne-Jones

Dr. W. F. K. Wynne-Jones, whose election to the chair of chemistry in University College, Dundee, in succession to Prof. A. McKenzie is announced on p. 843, was educated at Monkton Combe School, Bath, whence he proceeded to the University College of Wales, Aberystwyth, and to Balliol College, Oxford. Later, as research assistant to Prof. J. W. McBain at the University of Bristol, he carried out experimental work on the Gibbs adsorption equation. In 1927–28, during the tenure of a Rockefeller fellowship, Dr. Wynne-Jones undertook a research on the problem of acids and bases under the direction of Prof. J. N. Brønsted in the University of Copenhagen. In 1933, he was awarded a Leverhulme fellowship which he held at Princeton University; where, in the laboratory of Prof. H. S. Taylor, he worked on the extent of the electrolytic dissociation of heavy water and the comparative rates of ionization of hydrogen and deuterium. In 1935 he published, in collaboration with Prof. H. Eyring, an important paper on the absolute rate of reactions in condensed phases. His recent work has furnished new information on the mechanism of ionic reactions. Since 1928, Dr. Wynne-Jones has held a lectureship in physical chemistry at the University of Reading.

Coal and Smokeless Fuel

The Coal Measures of Great Britain, for all the depression in the coal industry, are still a great national asset. The article on "Oil from Coal" on p. 812 of this issue brings up once again the question of their proper utilization. It is common knowledge that it is technically possible to produce motor-spirit from coal: the difficulty is to find a reasonably satisfactory method. It appears, however, that we are now reaching a stage when it is legitimate to regard our seams of coal in the light of a series of oil-bearing deposits, since 'crudeable' products can now readily be produced from them. If the estimates of production costs given by Mr. Strevens and Mr. Cross are correct, and the coal-oil distillation process is the cheapest available, then, on the basis of this process, the Coal Measures of Great Britain are comparable with good medium-grade oil sands or shales.

The economically workable oil deposits of the world yield crude petroleums giving from 20 to 70 per cent of motor-spirit; the crude distillates produced from British coals by coal-oil distillation give 35–45 per cent or more; thus they fall in the middle of the range, on a par, for example, with Southern California oil stock. We should also recollect two further points. First, the hazards of extracting coal from the coal measures are, in general, considerably less than those of extracting petroleum from oil deposits. These latter hazards may be visualized by recalling that nearly a third of the million or so oil wells drilled in the U.S.A. are stated to be dead or abandoned. Secondly, the world's total reserves of motor-spirit to be extracted from coal are considerably larger than those to be extracted from petroleum.

There is another aspect of the question. The coal-oil distillation process yields a considerable amount of high-grade smokeless fuel. Thus its development might serve a triple function. It might in the first place (like any other satisfactory process of obtaining motor-spirit from coal) render Great Britain less dependent on external supplies of motor-spirit. In the second place, at any rate so long as tax discrimination in favour of home-produced motor-spirit is continued, it opens up the possibility of establishing an export trade in cheap smokeless fuel, thus helping materially to relieve unemployment and economic distress in the coal industry. In the third place, like any other process yielding cheap smokeless fuel, it holds out a hope of ridding Britain of much of the smoke which is not only productive of so much waste and material damage, but also so destructive both of health and of amenity. It is clear that we are entering on a new phase as regards coal. In the first, pre-industrial stage, coal was little more than a curiosity—a combustible mineral which here and there was used in preference to wood. In the second place, coal became the mainspring of industry, but was regarded simply as a fuel. In the third phase, now dawning, we must accustom ourselves to think of coal as a raw material generally demanding special treatments for its proper utilization. The new concern for health and social welfare is demanding that methods for preventing smoke shall be adopted, even if at some economic sacrifice. Coal-owners and public alike must learn to regard coal as a store of riches which it is for science and technology to unlock and make available.

Bureau of Animal Population

The modest report of the Bureau for 1936–37 contains much of practical as well as of scientific interest, and this is vouched for by the contributions made towards its upkeep by the Medical Research Council, the Forestry Commission, the Agricultural Research Council, Imperial Chemical Industries Ltd., the Partridge Research Fund, and Hudson's Bay Company Ltd. At the same time, these varied patronages suggest something of the extent of interests served by Mr. Elton and his colleagues. The research on vole populations in itself touches upon many interests: fluctuations in numbers of voles are of immediate concern to the farmer and forester, and to the ecologist they present problems still awaiting solution; the discovery of a disease closely resembling tuberculosis in a large proportion (22 per cent) of voles trapped in areas ranging from the north-east of Scotland to Buckinghamshire, may give a clue to the high death-rate which closes a vole plague, and may have some relationship with human and bovine tuberculosis. These and other vole matters are engaging the attention of a strong team of scientific workers. Research on partridge fluctuations continues, and from 1938 for a period of three years at least, data are to be collected and a much-needed analysis is to be made on the periodic fluctuations of rabbits and hares in Great Britain. It says something for the desirability of scientific investigation and propaganda, that in the report from the Select Committee of the House of Lords on Agriculture (Damage by Rabbits), running to some 270,000 words, less than a hundred were devoted to research.

Apart from its British inquiries, the Bureau has given its help to investigations in North America on fluctuations in numbers of the snowshoe rabbit, an arctic wild-life inquiry, and on the evidence in the Hudson's Bay Company's archives of a ten-year cycle in fur-bearing animals. The only unsatisfactory feature of the report is concerned with finance. Although in this respect the position of the Bureau seems more assured than in former years, the fact that it is kept in being by grants drawn from fourteen different sources, suggests that the collecting of moneys must occupy an undesirably large proportion of the time and energy of the scientific worker responsible for its organization, and that the staff must be labouring under some uncertainty as to their future. Neither condition is conducive to the best scientific work, and we look forward to a day when the Bureau will become an integral part of a State-organized biological survey.

The Ebro and Zi-Ka-wei Observatories

It has been from time to time a pleasure during the protracted civil war in Spain to receive the *Boletin del Observatorio del Ebro* and to realize that the famous Jesuit observatory was working away peacefully in Republican Spain. Father Rodés and his staff have been carrying on their heliophysical, meteorological and seismological work steadily with support from the Government—last year their grant was paid in full—the autonomous Government of Catalonia and the municipal councils of Villanova and Geltru, though they have been faced with severe difficulty in securing necessary scientific material and have been naturally unable to collect meteorological data from their observers scattered throughout Spain. Now comes the sad news, reported by the Burgos correspondent of *The Times* (April 25), that the tide of war has swept over them and that instruments have been dismantled and damaged during the hostilities, while the director, Father Rodés, has been taken to Barcelona. It is to be hoped that he will soon be released and enabled to return to his observatory and to restart the many series of observations of international importance that have been thus forcibly interrupted. Nothing much has been reported about another famous Jesuit geophysical observatory, that at Zi-Ka-wei, close to Shanghai, with its astronomical sub-station at Zô-Sè, some forty miles away. They, too, have lain in a ravaged war zone, but their latest publication from Zô-Sè ("Perturbations générales par Jupiter et Saturne sur 40 petites planètes", par le P. E. de la Villemarqué, *S.J.*) received less than a week ago, suggests that the astronomers have been allowed to carry on unmolested.

Royal Institution

THE annual meeting of the Royal Institution was held on Monday, May 2. In the unavoidable absence of the president, the chair was taken by Sir Robert Robertson, treasurer and vice-president. The customary report of the Committee of Visitors and statement of accounts were presented at the meeting. It was stated that the vacancy in the professorship of natural philosophy caused by the death of Lord Rutherford has not yet been filled; Sir James Jeans has been re-elected professor of astronomy and Sir Frederick Keeble has succeeded Sir Edward Mellanby as Fullerian professor of physiology. An important addition has been made to the equipment of the lecture theatre by the installation of a talking cinematograph projector, which it is expected will be of increasing value as talking films and films with sound effects come more generally into use for lecture illustrations. Early last year, a fire at No. 19 Albemarle Street, which is partly occupied by the Institution, was fortunately discovered and extinguished before it had become extensive; the damaged books and other effects have now been restored, and the loss was fully covered by insurance. The treasurer's report showed that the legacy of the late Mr. Harry Brown, now completed, has resulted in an addition to the funds of the Institution of no less than £30,987 3*s*. 2*d*. Important subsidies for the researches in progress include £500 per annum for a further period of three years from the Anglo-Iranian Oil Company, £500 per annum for five years from the Leverhulme Trustees, and a Coronation gift of £2,000 from Sir Robert Mond.

"MEMBERS are less familiar with, because they see less of, that important part of the Institution's activities, the research work which is carried on under Sir William Bragg's direction," say the Visitors in speaking generally of the Royal Institution's work. The wide range and great interest of the researches may be gathered from the report of the Davy Faraday Laboratory, printed as a supplement to the Visitors' report. Researches quoted include those on the X-ray structure analysis of nickel phthalocyanine and stilbene; on the dielectric polarization of long-chain ketones, and on the X-ray study of metals, beginning with the elastic properties of single crystals of sodium. The optical work on methane and CH_3D has been further developed, and a new type of absorption tube, using the Rowland grating, has been employed. It is recorded that the large X-ray generator has now been tested to its full capacity of 50 kilowatts; and a research programme in connexion with this generator, including high-dispersion measurements on metals, is spoken of. The following officers were elected at the meeting: *President*, Lord Eustace Percy; *Treasurer*, Sir Robert Robertson; *Secretary*, Major Charles E. S. Phillips; *New Managers*, Sir Frederick Berryman, Dr. F. H. Carr, Prof. F. L. Hopwood, Mr. P. V. Hunter, Sir Richard Paget, Dr. A. O. Rankine, Dr. R. Seligman, Prof. G. P. Thomson; *New Visitors*, Dr. W. R. Bisschop, Mr. E. R. Bolton, Dr. W. A. Caspari, Prof. C. D. Ellis, Dr. W. Hall, Prof. J. T. MacGregor-Morris, Dr. L. C. Martin, Mr. C. Rowntree.

Exhibition of Buddhist Paintings

IN the exhibition of Buddhist paintings now open in the Edward VII Gallery of the British Museum (Bloomsbury) the examples shown have been selected with the view of demonstrating the different types of religious painting which have been produced by Buddhist thought and belief in the varying environment of, so far as possible, the whole of mid- and farther Asia. It covers the manifestations of Buddhist religious art in China, Japan, Korea, Siam, Tibet and Turkestan. No equally comprehensive exhibition has ever been held previously in England. The opportunity for such a display has arisen through the acquisition of several important paintings from Korea and Siam with the Eumorfopoulos collection, which also includes the first two examples to reach the Museum of the wall paintings recovered from Turfan by A. von Le Coq. Tibetan painting is represented by a selection from a series of the sixteen Arhats and the four Lokapalas from a temple at Shigatse, deposited on loan by Mr. J. C. French. They are much earlier than those usually seen in Europe. Of great interest to the student of early Far Eastern painting are the Japanese reproductions in collotype of the famous eighth-century wall paintings from the Buddhist shrine at Hōryūji. The five shown are each twelve feet high. These paintings are especially remarkable, owing to the fact that they are examples of the fresco art of the T'ang period of China, which has vanished from her own soil. In an official account of the exhibits, it is justly pointed out that the key to the exhibition is the full selection from the paintings recovered by Sir Aurel Stein from the sealed chamber of the Caves of the Thousand Buddhas, near Tun-huang in Sinkiang. Some of the woodcuts from the same source are the earliest known in the world. To round off the demonstration, reproductions of the Ajanta frescoes are shown as an indication of the different kind of painting produced in the original home of Buddhism. The common bond in the religion which all these schools of painting served, indicates the extent to which these parts of Asia formed a cultural unity; while the examples themselves illustrate the richness and variety of religious painting in the East.

Special Libraries and Information Bureaux

THE Association of Special Libraries and Information Bureaux held a luncheon on April 27 at which a company of more than eighty was present. After saying that he hoped the luncheon would become an annual event, the president, Sir Harry Lindsay, director of the Imperial Institute, spoke of the three stages of science: first scholasticism, dominated by the great men of science, then the period of the authoritative text-books, now the era of the individual specialist. The results of modern scholarship are scattered in innumerable technical journals and, in order to keep abreast, search must be made over a very wide field. The same is no less true of other spheres of knowledge. ASLIB was therefore formed to act as a guide to specialist sources of information. The next speaker, Sir Clement Hindley, chairman of the Racecourse Betting Control Board, mentioned his connexion, as vice-president, with the Institution of Civil Engineers. The Institution's abstracting service, started so long ago as 1877, he said, has recently been considerably expanded in collaboration with other institutions representing different branches of engineering. This expansion should interest all who, as members of ASLIB, are eager to facilitate the dissemination of knowledge. Sir Ian MacAlister, secretary of the Royal Institute of British Architects, stated that in the nineteenth century people created every sort of institution and machine, political, social and mechanical. In the post-War years of disillusionment, we realized that machines are of no use unless they work, museums are a costly extravagance unless their treasures can be made intelligible, and libraries are mere hoards of books if inaccessible to those who need them. A new desire to make the instruments of civilization work is now awake, and ASLIB is a valuable and essential part of this great movement.

Prehistoric and Primitive Iron Smelting

IN a paper bearing the above title read to the Newcomen Society on April 20, Mr. E. W. Hulme reviewed the history of the use and manufacture of iron through a period of about 3,000 years, from the date of the earliest known examples of beads made of meteoric iron down to about the first millenium. The first example of terrestrial man-made iron, he said, was the iron dagger found by Woolley at Tell Asmar in Mesopotamia. Unlike objects made from meteoric iron, this is free from nickel. Besides the objects found in tombs and the fragmentary records such as the diplomatic correspondence recorded in the clay tablets of Egypt and Asia Minor, Mr. Hulme dealt with the sites and processes associated with early iron making. These included the Egyptian by-product iron process by which very small amounts of iron were obtained from sands containing magnetite and gold; the Wootz steel-industry of southern Central India, the Chalybian steel process described by the Pseudo-Aristotle (fourth century B.C.), the iron industry of Persia and the Gerar forges of Southern Palestine. The claims of Persia to rank amongst the earliest makers of iron have been overlooked, but if they can be substantiated the migration of the industry to China, India, Syria and Palestine becomes explicable. When referring to the Gerar forges of Palestine described by Sir Flinders Petrie, Mr. Hulme said that though his interpretation of the purposes of the furnaces differed from that of Sir Flinders, "for the recovery of these dateable sites and for the meticulous accuracy in the description of the large output of these forges, all metallurgists owe a warm debt of gratitude to the veteran explorer who has done so much to recreate for them the history of Egypt and the Near East".

Paris Television Transmitter

ACCORDING to a note in the *Wireless World* of April 21, a new television transmitter at the Eiffel Tower, Paris, was inaugurated on April 8 by the Minister of the French postal and telecommunications service. The transmitter, which has been in regular operation since September 1937 with reduced power, will shortly be broadcasting with its peak output of 30 kw., thus making it one of the most powerful television stations in the world. The aerial is supported by the Eiffel Tower and connected to the transmitter by a cable 380 metres long. Two new studios with the most up-to-date equipment are situated at distances of 2·5 and 5 kilometres from the transmitter, to which they are connected by co-axial cables. The vision modulation frequencies are impressed on a carrier frequency of 5·5 Mc./sec., the total band transmitted down the cable being from 3 to 8 Mc./sec. The transmitter is designed to operate on a frequency between 40 and 50 Mc./sec., at its continuous peak power output of 30 kw. The frequency is maintained constant within narrow limits by a quartz crystal oscillator, followed by two doubler stages, which raise the frequency to the final carrier value. Some further technical details of the transmitter are given in the article to which reference is made above.

X-Ray and Radium Protection

THE fifth revised report (January 1938) of the British X-Ray and Radium Protection Committee shows that the Committee is alive to the necessity of continually adjusting its recommendations to the expanse of its subject. The chief additional items in this report are to be found in Section v, dealing with the necessary electrical precautions in X-ray rooms, in Section viii (*C*), which deals with radium teletherapy, and in Section ix, where the incidental dangers in the use of electro-medical apparatus, especially apparatus activated from the mains circuit, are considered. This report contains a valuable appendix giving the equivalent thickness of lead and materials in use for general radiation protection; the data are supplied by the National Physical Laboratory. The services of the Laboratory are largely made use of by those in charge of radiological departments, both in a consultative capacity in planning, and for purposes of test when the assembly of apparatus is completed. Copies of the report are sent free on application to the Hon. Secretaries of the Committee, 32 Welbeck Street, W.1.

Pests of Ornamental Plants

THE attention of garden lovers and horticulturists is directed to Bulletin 97 of the Ministry of Agriculture and Fisheries, entitled "Pests of Ornamental Garden Plants" (1937). This publication deals with an aspect of horticulture seldom adequately treated in text-books on insect and other pests. The problem of controlling pests in gardens is, moreover, different from that of the commercial grower. The author of this work is Mr. G. Fox Wilson, entomologist to the Royal Horticultural Society, and he has provided authoritative and practical advice on the pests in question. General measures of control are discussed and the different pests are described under their respective headings, such as lawns, the annual border, rock garden, glass houses and so on. The work is well and fully illustrated, while the price of 3*s*. 6*d*. net is very reasonable for a Bulletin strongly bound and containing more than 100 pp. of letterpress. It can be obtained from H.M. Stationery Office, Adastral House, Kingsway, W.C.2, or through any bookseller.

A Binocular Illusion

REFERRING to Prof. H. H. Dixon's letter in NATURE of April 30, Miss E. Armitage, Dadnor, Ross, Herefordshire, writes to suggest that the checkerboard appearances may be akin to that commonly observed when studying photographs of lunar phenomena, the 'walled plains' sometimes appearing as convexities and sometimes as concavities, according to which side the shadow appears to fall.

World's Congress of Faiths

A WEEK-END Congress of the World's Congress of Faiths (Continuation Movement), of which Sir Francis Younghusband is chairman, will be held at Regent House, Cambridge, on June 24–28, when the subject under discussion will be "The Renascence of Religion". Addresses will be delivered by representatives of the various religions, with discussions to follow. Among the speakers who have already promised to address the Congress are Sir Sarvepalli Radhakrishnan, Spalding professor of eastern religions in the University of Oxford, for whom Canon C. E. Raven, regius professor of divinity in the University of Cambridge, will take the chair, and Baron E. K. Palmstierna, formerly Swedish Minister to the Court of St. James, for whom the Master of the Temple, Canon H. Anson, will preside. Members of the Congress will be accommodated in St. John's College (men) and Newnham College (women). Particulars of membership and other arrangements may be obtained from the Secretary, World's Congress of Faiths, 36 Victoria Street, London, S.W.1.

Presentation of Kelvin Gold Medal

THE Kelvin Gold Medal for 1938 was presented to Sir Joseph Thomson, master of Trinity College, Cambridge, in recognition of the eminent services he has rendered to engineering science, by Lord Rayleigh, in the Great Hall of the Institution of Civil Engineers on May 3. The executive committee of the memorial fund to Lord Kelvin, representative of nineteen British and American Institutions, decided that the balance of the Fund, after defraying the cost of a window unveiled in Westminster Abbey to the memory of Lord Kelvin in July 1913, should be applied to the establishment of a Kelvin Gold Medal to be awarded triennially as a mark of distinction in engineering work or investigation of the kinds with which Lord Kelvin was especially identified. The award of the first Kelvin Medal was delayed by reason of the War, and it was not until 1920 that the first award was made to the late Dr. W. C. Unwin (Great Britain). The following awards have since been made: Dr. Elihu Thompson (United States); Sir Charles Parsons (Great Britain); M. André Blondel (France); Marchese Marconi (Italy); Sir Ambrose Fleming (Great Britain).

Presentation of James Alfred Ewing Medal

MR. S. B. DONKIN, president of the Institution of Civil Engineers, presented the James Alfred Ewing Medal to Mr. Charles Samuel Franklin immediately before the delivery of the James Forrest Lecture by Sir Frank Smith. This Medal was founded in 1936 in memory of Sir Alfred Ewing, an honorary member of the Institution, and is awarded for specially meritorious contributions to the science of engineering in the field of research, on the recommendation of the presidents of the Royal Society and of the Institution of Civil Engineers. Mr. C. S. Franklin is well known for his inventions and developments in connexion with beam wireless. The rotating beam aerials installed experimentally at Poldhu in Cornwall were designed by him, whilst he was also responsible for the concentric feeder system for supplying energy to radio aerials and enabling extremely high-frequency currents to be transmitted along a line without loss. These feeders are used in the beam system and are essential to television transmission circuits.

Ninth International Ornithological Congress

THE ninth International Ornithological Congress, which will be attended by ornithologists from every part of the the world, will be held in Rouen on May 9–14. Later, the members of the Congress will proceed to Paris and the programme will terminate with a long excursion to the bird reserves in the Camargue. All questions concerning the preservation of birds will be dealt with at the meetings of the International Committee for Bird Preservation, which will be held immediately before the Congress. These meetings are confined to the official delegates of the national sections, which are operating in twenty-eight different countries, of the Committee. In connexion with the Congress an international exhibition of bird pictures is being held in Paris on May 14–29. British ornithological art will be represented by the works of Roland Green, G. E. Lodge, Peter Scott, Archibald Thorburn (lent by Messrs. W. F. Embleton) and A. W. Seaby (lent by Mr. A. W. Harvey Brown, Stevens and Brown Gallery).

Travelling Fellowships in Medicine

THE Medical Research Council invites applications for six Rockefeller Medical Fellowships for the academic year 1938–39. These are provided from a fund with which the Council has been entrusted by the Rockefeller Foundation of New York and are intended for British graduates who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in the United Kingdom. The stipend will ordinarily be at the rate of £360 per annum for a single Fellow, and of £480 per annum for a married Fellow. Travelling expenses and some other allowances will be paid in addition. The Council also invites applications for four Dorothy Temple Cross Research Fellowships in tuberculosis, which are awarded from a special endowment of which the Council is the trustee. The object of these fellowships, as defined in the trust deed, is to give special opportunities for study or research to suitably qualified British subjects of either sex "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms". The stipend will ordinarily be at the rate of £360 per annum for a single Fellow, and of £480 per annum for a married Fellow, with an allowance for travelling and incidental expenses. Completed applications for fellowships of either type must be lodged with the Council not later than June 1. Further particulars and forms of application are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S.W.1.

Announcements

THE Council of the Royal Society of Edinburgh has awarded the Neill Prize for the period 1935–37, to Prof. William J. Hamilton, St. Bartholomew's Hospital Medical College, for his contributions to the embryology of the ferret and other work published in the *Transactions* of the Society.

THE first of the two annual soirées of the Royal Society will be held on May 18.

THE Frankfort Senckenburg Society of Natural Science has awarded Prof. W. H. Hoffmann, director of the Finlay Institute of Havana, the Great Iron Medal of Honour, which is the highest distinction conferred by the Society, in recognition of his researches on tropical medicine.

IN NATURE of April 23 (p. 745), two record-breaking flights in gliders were announced. A new distance record was made on April 30 by Mr. Philip Wills, who flew from Heston to St. Austell in Cornwall, a distance of about 206 miles.

THE Challenger Society will be making further grants in aid of research during the current year. The general committee is prepared to consider applications for some grants in aid of research in marine biology, the work preferably to be carried out at one of the recognized laboratories. Applications, accompanied by details of the proposed research, should reach the Honorary Secretary, Mr. J. R. Norman, British Museum (Natural History), S.W.7, before the middle of June.

FARMERS and all interested in agriculture in its practical, technical or educational aspects are cordially invited to visit the Rothamsted and Woburn Experimental Stations at any convenient time between the beginning of May and the end of October. Mr. H. V. Garner and Capt. E. H. Gregory will be in charge of the demonstrations, and there is ample material at either of the farms to occupy a full day. Further information can be obtained from the Secretary, Rothamsted Experimental Station, Harpenden.

THE Royal Sanitary Institute is giving a further course of lectures and demonstrations on pasteurization for medical officers of health, sanitary inspectors and others interested on May 26 and 27. Further information may be obtained from the Secretary, Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1.

AN institute for the study of the causes and treatment of influenza has recently been established at Budapest.

THE Cuban Government has recently allotted a million dollars from its lottery funds for a campaign against tuberculosis. Clinics are to be established throughout the country for the examination of every citizen.

THE first French Congress of Good Bread will be held at Nice on May 14 and 15. Further information can be obtained from the General Secretary, M. Robert Septembre, 16 rue de l'Hotel des Postes, Nice.

THE International Red Cross Conference, which was to have met in Madrid this year, will be held in London on June 20–24. The opening and closing sessions will take place at St. James's Palace, and the other meetings at the British Medical Association House, Tavistock Square, where further information can be obtained.

THE third International Congress of Tropical Medicine, which was to have been held at Amsterdam, and the third International Malaria Congress, which was to have been held at Madrid in 1935, had both to be postponed, but a joint congress will be held at Amsterdam on September 24–October 1 under the presidency of Dr. G. Gryns. Further information can be obtained from the Secretary, Mauritskade 57, Amsterdam 0.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

Notes on points in some of this week's letters appear on p. 836.

Correspondents are invited to attach similar summaries to their communications.

AN ETHICAL DECLARATION FOR THE TIMES

In the last few years several of the most enlightened communities of Europe have been dispersed, and the principles of justice and tolerance openly challenged. More than this, the conception of the objective truth which is the basis of science and of all human progress is being steadily undermined. European civilization has had profound failings, but we must either devote our energies to maintaining and developing what is good in it or accept a collapse into a barbarism of violence and intolerance. The greatest danger to-day lies in the complacent illusion — seen so often in history and now prevalent in the more fortunate countries—that civilized traditions are an inalienable legacy which can be enjoyed indefinitely by generations which are no longer ready to make sacrifices for them.

It is my belief that men in all countries who do not wish to betray the tradition they have inherited must now discard false modesty and announce clearly for what they stand. We do not deserve and we shall not long retain the fruits of a civilization to which we do not declare and prove our active loyalty. More than two thousand years ago the Hippocratic Oath was used to promote amongst practitioners of the art of medicine certain standards appropriate to their task. It is suggested that a Declaration such as that here reproduced should be offered to-day by cultural, educational, and technical institutions throughout the world to their members. The advance of intolerance and of the lie can only be reversed by awakening a militant loyalty to the principles of a world civilization, and this loyalty must be focused in special symbols and instruments.

DECLARATION

I AM the inheritor of the tradition of civilization which has proved more lasting than empires. Whenever I use the language or the products of science I unconsciously pay homage to the countless men for whom no sacrifice was too great in the struggle to develop the human mind and establish the truth. Toleration and freedom are the heart of this tradition; for individual thought and love of truth are the basis not only of science, but also of justice and of civilization.

I DECLARE my loyalty to this tradition, my belief in the freedom of the individual to develop his talents for the enrichment of the community, and my conviction that man's community is now the whole human race, within which each nation must play its characteristic part. The natural balance between personal freedom and the proper demands of society, which is the life and health of civilization, is to-day doubly threatened: in certain societies by the denial of freedom and in the democratic countries by the irresponsibility of individuals. In the face of this threat:

I PLEDGE myself to use every opportunity for action to uphold the great tradition of civilization, to protect all those who may suffer for its sake, and to pass it on to the coming generations. I recognize no loyalty greater than that to the task of preserving truth, toleration, and justice in the coming world order.

Though the Declaration is designed on the broadest human basis to appeal to all who understand what civilization means, it is appropriate that it should appear first in Nature. Science is to-day the only non-partisan and universal authority, and its principles are at stake. If the Declaration is timely it may either serve as the stimulus to a special declaration of scientific faith by the scientific organizations in all countries, or spread from this background to wider circles.

The Declaration is copyright-free for reproduction or translation. Arrangements have been made to have it printed on cards, and copies may be had from For Intellectual Liberty, 23 Haymarket, London, S.W.1. at cost price.

Carriers of Foot-and-Mouth Disease

THE highly sporadic character of the occurrences of foot-and-mouth disease in Great Britain and its apparently repeated importation from the Continent have naturally caused much speculation about possible vectors, though the special difficulties of the case have prevented the direct demonstration of carriage.

Birds have often been incriminated, and Prof. A. C. Hardy, in his letter in NATURE of April 2, further suggests that insects may be carried far enough by air-currents even over the sea, to be considered also as possible carriers.

Neither birds nor insects can, however, be regarded as primary vectors, since neither group, so far as is known, can harbour the virus systemically, and viruses do not survive extra-cellularly for more than short periods. They can only be secondary carriers of the true agent of transmission. This might take the form of skin or hair particles or excreta of infected animals, adherent to the carrier, though the probability of birds, at any rate, becoming heavily contaminated in this way is not very great. It is not even necessary, in such circumstances, to assume the need for any vector, since the carrier material may equally well be disseminated by wind.

In this connexion it is perhaps worth while to direct attention to the work of L. A. Silber and his co-workers[1,2] and of Poppe and Busch[3] on the symbiosis of viruses and yeasts. The former have shown that smallpox and vaccinia viruses enter the yeast cells and form a close union with them, of an enduring character. The virus-yeast complex is passed intact from cell to cell during proliferation and the virulence may apparently be retained for an unlimited period. Variola virus has been propagated in this way through more than a hundred cell-generations. Poppe and Busch showed that the same is true of the foot-and-mouth virus, which also remains viable with the yeasts in serial sub-culture.

Yeasts of many kinds, *Torulopsis*, *Rhodotorula*, *Mycotorula*, *Candida*, *Sporobolomyces*, etc., abound in the soil and in the atmosphere, in which latter they sometimes outnumber the bacteria. In the air they seem to have a random distribution, considered as a population, but this is not the case for particular species, which are often to be found in local concentrations, strongly suggesting, as Trillat[4] claimed, that they can multiply in the air.

The possible importance of the aeroplankton yeasts as virus carriers is not, of course, limited to the case of foot-and-mouth disease, but it cannot be overlooked in any case. If it can be proved that yeasts carrying viruses of any type occur naturally in the free atmosphere, then the impossibility of precluding chance infection must be manifest and the importance of immunity in the subject is correspondingly enhanced.

The suggested role of yeasts as carriers is not limited to animal viruses. It may also provide the clue to the apparently vectorless outbreaks of tobacco necrosis recorded by Smith and Bald[5] and to Smith's observation of an air-filter contagion[6].

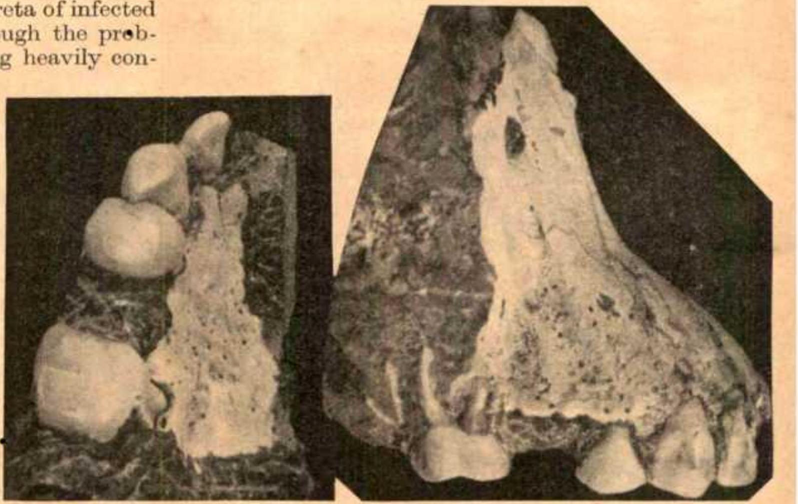
More Discoveries of *Australopithecus*

A FEW months ago I sent an account to NATURE[1] of the discoveries of a number of teeth of *Australopithecus*. The principal of those was a beautifully preserved third lower molar, but I also had found a new third upper molar and much of a first incisor.



(*a*) (*b*)

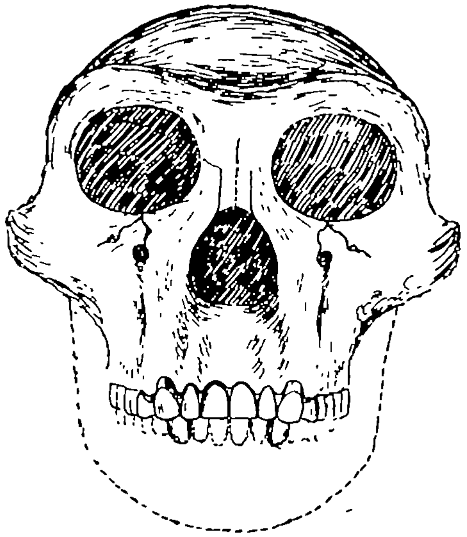
Australopithecus transvaalensis BROOM. (*a*) OCCLUSAL VIEW OF RIGHT UPPER TEETH AND PART OF PALATE; PART OF THE BACK OF THE CROWN OF THE FIRST MOLAR HAS BEEN DAMAGED BEFORE FOSSILIZATION. (*b*) SIDE VIEW OF RIGHT MAXILLA; NOTE THE REMARKABLY HUMAN-LIKE INCISOR AND CANINE. NATURAL SIZE.

Since then nothing more was found until two weeks ago, when a fairly well-preserved lower canine was discovered. This is so like a human canine that I hesitated to describe it in case it might prove to be human. The whole length of the tooth is about 32 mm., but as the tip of the crown is lost the exact length is uncertain. The crown cannot have been more than 10·5 mm. in height. The base of the crown measures 9 mm. by 6·3 mm. It is like the human lower canine, but the face of the crown is in *Australopithecus* directed more outwards than forwards. It bears no close resemblance to that of the chimpanzee either in size or shape.

Then last week I made a much more important discovery—a nearly complete right maxilla in good condition and with the second incisor, the canine, the first premolar and first molar in position. The premolar and the molar agree so closely with those of the type as to leave no doubt that the jaw is of the same species—*Australopithecus transvaalensis*.

me importance as it
much more enlarged
nd down to the same
d the second incisor ;
incisor, which is smaller
up to the canine.
eserved with part of the
ow know the width, and the
revealed that the molar teeth do
, as in the gorilla and chimpanzee, parallel
but rounded arches as in man.

The nostril measures about 23 mm. in width and the nose has probably been fairly similar to that in the chimpanzee. The infraorbital foramen is large and oval and lies 9 mm. from the orbital margin.



FACE OF *Australopithecus transvaalensis* BROOM, PARTLY RESTORED. × ½.

The face agrees fairly closely with that of the chimpanzee, except that the reduction in size of the incisors and canines makes the anterior part of the snout much narrower and shorter. One might describe *Australopithecus* as a chimpanzee with human teeth. Whether it is a descendant from a chimpanzee-like ancestor or near the common ancestor of man and the chimpanzee need not at present be more fully discussed. Most will agree that if it had large canines it would be near to the chimpanzees, and if it had a large brain it would be near to man. Possibly it is near to the human ancestor, and it may be that man arose from a form like *Australopithecus*, by a mutation resulting in a large brain. Whether such a mutation was an accident or the result of the work of some spiritual force, opinions will differ.

Gilding of Copper among the Pre-Columbian Indians

I HAVE already given an account[1,2] of certain investigations regarding the metallurgical methods employed by the pre-Columbian Indians, especially their methods of procuring platinum in coherent form without fusing it, and I have demonstrated the metallurgical processes adopted by them in soldering by 'sweating', wire-drawing, the plating of gold with platinum, etc. Further investigations have now disclosed the fact that the Indians, at any rate those in the Esmeraldas district, gilded their copper objects in a fashion which appears to have been completely unknown hitherto, both to the ancient world and to us. It was previously supposed that such gilding must have been carried out in America with the help of mercury. Although it has been impossible to demonstrate traces of mercury in any of the gilded objects, no other explanation has been suggested.

After cleansing such objects to remove the products of corrosion and the remnants of gold still adhering to them, I have shown by chemical analysis that the copper contains varying quantities of gold in alloyed form—the largest amount on the surface and decreasing gradually towards the centre. Such unequal gold content might well be imagined to have arisen from the melted gold permeating the copper. Gilding must have been done by dipping the copper into a melted gold-copper eutectic (gold with about 20 per cent copper) the melting point of which is some 200° C. lower than that of copper ; or possibly, the gold-copper alloy was applied to the copper and kept at red heat on charcoal by means of a blowpipe. The alloy will then fuse and run over the copper without the use of flux being necessary, the reducing flame securing a glowing surface free of oxide. Investigations have shown that copper has a tendency to absorb the melted alloy in the same manner as melted tin permeates copper or a zinc rod absorbs mercury. The copper nucleus thus becomes a gold-copper alloy richest in gold at the surface, the amount of gold decreasing gradually. After the gilding process had thus been accomplished, the reddish tinge of the coating was improved by boiling out in pickle—in French, *mise en couleur*, in German, *Abochung*—a method with which, we know with certainty, the Indians were acquainted.

I have examined breastplates covered with gold, but only on one side, originating from Ecuador. These plates appear to have been beaten out from thicker plates which had already been gilded. This is quite feasible if care is taken that the gilding is not too thick. Gilding was used by the Esmeraldas Indians for other purposes than decoration. Of the thirty-five fish-hooks found, all were gilded, but not one single specimen of thirty-two sewing needles discovered. The gold which penetrates the copper fish-hooks makes the metal much harder, and hardness is the first consideration in a fish-hook.

Objects gilded in this manner are far more exposed to the attacks of corrosion than copper, and this probably has been a contributory factor to the difficulty which previous investigators have had in discovering the above facts.

Investigations have also shown that it is possible to silver copper in the same way.

A detailed statement will be made on the occasion of the Anthropological Congress which is to be held in Copenhagen this summer.

A Colorimetric Method for the Estimation of Nicotinic Acid in Foodstuffs

RECENT investigations[1,2,3,4] have shown that pellagra in human beings, black-tongue in dogs and pellagra-like symptoms in pigs, can be cured by the administration of nicotinic acid, and nicotinic acid is probably identical with, or a precursor of, the pellagra-preventive (P.-P.) factor. Hence the question of estimating the nicotinic acid content of foodstuffs is of immediate importance and interest.

A method has been developed based on the colour produced by the pyridine ring[5] when acted upon by cyanogen-bromide and aniline. A hot aqueous extract of the test foodstuff is freed from protein derivatives by lead acetate, the excess of lead being removed by sulphuric acid; the extract is brought to *p*H 10 and any colour present is removed by boiling with charcoal. The clear colourless extract is adjusted to *p*H 7·5 and made up to volume.

Aliquot portions of the extract and the standard nicotinic acid solution are each diluted with water to the same volume (20–30 ml.) in 100 ml. separating funnels; 4 ml. of freshly prepared aqueous cyanogen-bromide solution is then added to each and the mixture shaken and allowed to stand for half an hour. 4 ml. of a saturated aqueous aniline solution is then added and the mixture again shaken. The yellowish-green colour produced is then extracted three times with 10 ml., 5 ml. and 5 ml. portions of purified amyl alcohol[5] and the colours compared after standing for two hours.

The method is extremely sensitive—0·01 mgm. of nicotinic acid is easily detected—and the gradation of the colour produced is excellent for increments of 0·01 mgm. up to 0·1 mgm. of nicotinic acid. The whole procedure is simple.

The method has been applied to twelve foodstuffs. Further, known amounts of nicotinic acid were added to known amounts of yeast and raw milled rice and the recovery was good in both cases. The results are shown in Tables I and II.

TABLE I

Name of Foodstuff	Nicotinic acid (mgm. %)
Yeast, dried (brewer's) . .	62 50
Skimmed milk powder . .	10·53
Wheat, whole	5 33
Ragi (*Eleusine coracana*)	3·08
Rice, raw, milled . .	2 38
Rice, parboiled, home-pounded .. .	2·78
Cambu (*Pennisetum typhoideum*) ..	2 50
Cholam (*Sorghum vulgare*)	1·82
Maize, white	1 48
Soya bean .	4 85
Red gram (*Cajanus indicus*)	5·33
Bengal gram	4 74

TABLE II

Foodstuff + nicotinic acid	Total nicotinic acid present (mgm. %)	Total nicotinic acid found (mgm %)	Error %
Raw milled rice 10 gm + 1 mgm nicotinic acid	1 24	1·29	5
Dried yeast 10 gm +10 mgm nicotinic acid.	16 25	15 85	−4

The colour reaction is probably given by all compounds containing the pyridine ring, and the assumption is made that nicotinic acid and its derivatives form the major port [illegible] common foodstuffs. [illegible] taken to verify this [illegible]

The low value of ma [illegible] because of the associa [illegible] maize. While true pellag [illegible] like condition (stomatitis) [illegible] it is quite possible that defic [illegible] an important defect of Indian [illegible] or millet.

Selective Oxidation as a Fundamental Principle in Metallic Protection

IT is known that the oxidation or tarnishing of iron and copper can sometimes be diminished by alloying with small amounts of aluminium, beryllium, chromium and silicon, and that some oxide films confer protection or even passivity—especially when they are so thin as to be invisible. Little has been done, however, to obtain reliable protection by controlling the composition of the films. Miyake[1] has noted that, in the case of copper containing more than 3 per cent aluminium, the oxygen content of the atmosphere used for the first heating is an important factor. Sloman[2] has recommended the introduction of beryllium into silver to prevent tarnishing, but the efficacy of this addition has been questioned by Raub[3], whose work suggests to us that some factor other than the composition of the alloy determines its behaviour.

A new derivation[4] of Wagner's expression[5] $(n_1+n_2)n_3\kappa E/F$ for the velocity constant of tarnishing or oxidation reactions following the parabolic law (where κ is the electrical conductivity of the reaction product, n_1, n_2 and n_3 the transport numbers of cations, anions and electrons respectively in the film and E_0 the affinity of the reactants for each other) has suggested the necessity of producing on the metal to be protected *a film of very low conductivity*. Alumina or beryllia will possess the required properties if pure; but the analogous case of silver chloride containing traces of cadmium chloride[6] considered in connexion with the work on the conductivity of alumina[7], suggests that small traces of silver or copper oxides in the alumina or beryllia film would greatly increase the conductivity, and therefore the rate of tarnishing or oxidation.

By pre-treating alloys containing aluminium or beryllium in a controlled atmosphere—designed to permit the oxidation of the alloying constituent only and at temperatures suitable for the necessary diffusion of this constituent to the surface—protective films of pure alumina and beryllia have been obtained in these laboratories. Application of this principle of selective oxidation has led to materials almost immune from 'tarnishing' and 'scaling'. A specimen of copper containing 5 per cent aluminium heated in air at 800° C. for four hours gained 50 mgm./sq. dm., developing a loose black scale; the same alloy previously heated in a hydrogen atmosphere containing water vapour at a partial pressure 0·1 mm. (which still permits sufficient oxidation to develop a film of *copper-free* alumina), remained quite undarkened and gained only 4 mgm./sq. dm. when heated under the same conditions. Similarly, silver containing 1 per cent aluminium was found to tarnish rapidly when exposed to a polluted atmosphere, whereas the same alloy pre-heated in damp hydrogen at 400° C. so as to produce an invisible film of *silver-free* alumina, suffered no change in appearance within thirty times this period; pre-heating in air at atmospheric pressure did not reduce the tendency to tarnishing.

Several other examples could be given and full results will be published shortly. It is hoped that this principle of selective oxidation will play an important part in overcoming the deterioration of metals.

Effect of Succinic Acid on the Respiration of Normal Human Muscle and Various Myopathies

Succinic acid has long been known to be oxidized rapidly by muscle and many other tissues. Experiments of Szent-Gyorgyi and co-workers[1] suggested that succinic acid and certain other dicarboxylic acids catalyse the aerobic respiration of muscle tissue. Conclusive proof for this catalysis in muscle tissue was given by Stare and Baumann[2], and its application to liver and kidney tissue was shown by Stare[3].

In current studies on the respiration of human muscle tissue, we have observed that in muscle taken from patients with myasthenia gravis and progressive muscular dystrophy, succinic acid fails to catalyse the aerobic respiration and is itself oxidized only to a very slight extent. Malonate was found to inhibit the respiration. With normal human muscle tissue we observed the expected catalytic result upon addition of succinic acid as well as malonate inhibition.

The experiments were done in Warburg manometers at a temperature of 38° C. and in a Ringer phosphate-glucose buffer at *p*H 7·4. The tissues were obtained by muscle biopsy and immediately ground in an ice-cold Latapie mincer. Succinate and malonate were added as the sodium salts in concentrations of 0·003 and 0·03 molar. The following table shows typical experiments:

Muscle	Condition	Q_{O_2}	Increase of Q_{O_2} with succinate (0 003 M)	(0 03 M.)	Decrease of Q_{O_2} with malonate (0 003 M)
Gastrocnemius	Myasthenic	3·9	+ 3 per cent	+ 8 per cent	– 47 per cent
Gluteal	Prog muscular dystrophy	3 7	+ 5 ,, ,,	+ 5 ,, ,,	– 38 ,, ,,

The percentage increase in U_{O_2} values with succinate calculated at 90 and 20 minutes were even more striking than the Q_{O_2} values presented.

These results are of particular interest since they suggest that certain disturbances in the intermediary metabolism of normal muscle may be associated with these myopathies. These experiments are being continued and will be reported in detail in a forthcoming communication.

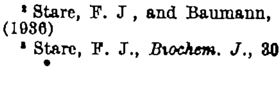
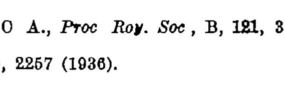
Vitamin B$_1$ and Cocarboxylase

The appearance of a paper by Lipschitz *et al.*[1] in which the authors consider that tissue extracts induce a synthesis of cocarboxylase from vitamin B$_1$ and phosphate by alkaline washed yeast prompts the publication of the facts below; they form part of an investigation on the phosphorylation of the vitamin suggested to me by Prof. R. A. Peters.

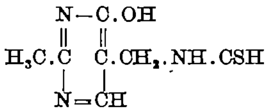
Lohmann and Schuster[2] found cocarboxylase to be vitamin B$_1$ pyrophosphate, but the vitamin itself was inactive as cocarboxylase. While confirming the latter fact, I find that the action of pure cocarboxylase is strongly stimulated by the addition of synthetic vitamin B$_1$. The graph which follows shows the activating effect of the vitamin on 1 γ cocarboxylase* using alkaline washed yeast and pyruvic acid. The pyrimidine group of the vitamin seems to be the one responsible for this activation. Pyrimidine I* has



I



II



III

about 1/10, pyrimidine II 1/30 the activity of the vitamin. Pyrimidine III, without the NH_2 group, is inactive up to 90 γ. This may be of significance in view of Langenbeck's findings[3] on artificial carboxylases. Thiazole (up to 90 γ) is inactive, as also is vicine, cytidylic acid (commercial specimen) and nicotinamide (up to 100 γ). The stimulation by the vitamin of the action of boiled tissue extracts is due to the presence of cocarboxylase in the latter.

The activation of the carboxylase reaction by vitamin B$_1$ is being explored for the estimation of both cocarboxylase and free vitamin B$_1$ in biological material. These results will be reported elsewhere. In the meantime, it seems clear that the discovery of this particular activation makes necessary a revision not only of the conclusions quoted above[1], but also of other present evidence for the synthesis of cocarboxylase from vitamin B_1.

Magnitude of Nuclear Forces

IN a recent letter to NATURE[1] it has been shown that the degree of dissociation of a proton or neutron is very close to $q = \frac{1}{2}$.

It can be shown that the so-called method of second quantization leads to essentially the same behaviour of elementary particles as the elementary theory. The numerical value of the degree of dissociation, however, remains undetermined, since it is proportional to the square of the interaction constant between heavy particle and heavy electron field. Thus, combining both methods, it is possible to determine the numerical value of the interaction constant. We obtain in this way the potential energy of nuclear forces

$$V = \pm A^2 \frac{e^{-\varkappa r}}{r}$$

where $A = \sqrt{\frac{hc}{2\pi} \frac{2m}{M}}$.

The details of the theory will be published in the *Physical Review*.

Mechanism of the Primary Photodissociation Processes of Organic Molecules

Two rules have been derived experimentally from investigations of the continuous absorption spectra of inorganic molecules[1]. First, the action of light may produce the splitting of a single bond, the two products of dissociation, namely, atoms or radicals, possessing free valencies. This process occurs as long as the central atom of the original molecule is in a lower state of valency, molecule formation being brought about by its p electrons only. The first long wave limit then agrees with the single bond energy concerned. The second mechanism refers to molecules the central atom of which is in its maximal state of valency, its s electrons being responsible for chemical linkage in addition to its p electrons. In this case, one of the dissociation products does not possess free valencies, but is a saturated molecule of lower valency state in a $^1\Sigma$ term. Here, the first long wave limit is not correlated to a single bond energy, but agrees with the energy difference of the total energy of formation of the original molecule and that of the produced molecule of lower valency. In other words, the action of light produces a transition to that repulsive electronic state, which is due to the repulsive character of the s^2 group of electrons and predicted by the pair bond theory of valency, originally advanced by Heitler and London.

In organic molecules the carbon atom is in its state of maximal valency and hence the above view should hold for organic molecules too. Indeed it has been verified already for simple tetrahalides of carbon. In addition to methan halides we have now studied aldehydes and ketones, acids and derivatives, ketonic acids and esters, a few examples being shown below. We have measured the continuous absorption spectra of some of them, while for others we used figures from literature, particularly the predissociation data as reported for aldehydes and ketones by Henri[2]. The results are in fair agreement with the theory, if we assume the following processes:

(1) $CI_4 \rightarrow CI_2(^1\Sigma) + 2I.$

(2) $H_2C{=}O \rightarrow 2H + CO(^1\Sigma).$

(3) $CH_3.CO.CO.CH_3 \rightarrow CO(^1\Sigma) + CH_3 + CH_3.CO.$

(4) $CH_3.CO.OC_2H_5 \rightarrow CO(^1\Sigma) + CH_3 + OC_2H_5.$

(5) $CH_3.CS.SH \rightarrow CS(^1\Sigma) + CH_3 + SH.$

Particular attention may be directed to the large shift of the predissociation point from the ultra-violet (λ 2750) in formaldehyde to the visible spectrum (λ 4395) in diacetyl, which is perfectly represented by the above theory. Also the long wave limits of further regions of selective continuous absorption in the far ultra-violet, measured for some such molecules, are capable of interpretation on these lines, comprising higher repulsive states of a similar character.

Substance	Process	Energy required calculated K.cal./mol.	observed λ (A)	K cal./mol.	Remarks	Author
Carbon tetra-iodide	(1)	70	3930	72	L. W. L	Samuel and Parti[1]
Formaldehyde	(2)	104 5	2750	103	Pr. D.	Henri and Schou[3]
Diacetyl	(3)	66	4395	64 5	Pr D.	Henri[2]
Ethylacetate	(4)	108	2630–2420	108–117	L. W L.	Present paper
Dithioacetic acid	(5)	84	3010	94	L. W L	,, ,,
			3360	84	Min. Sol.	,, ,,

L. W. L. = Beginning of continuous absorption (vapour) Pr. D = Predissociation of band spectrum. Min Sol. = Minimum of absorption curve of hexane solution.

In all such cases two bonds of the absorbing molecule appear to be broken simultaneously without involving two single bond energies, but by the direct transition from the ground state to a repulsive term, correlated to a saturated molecule of lower valency. A strict application of the pair bond theory seems, therefore, to offer an explanation of certain features of the spectra of organic molecules and, as we hope, of certain photochemical reactions and processes at the same time. This will be discussed at greater length in a forthcoming paper.

Band Spectrum of Silicon Monosulphide

In a recent paper[1] on the ultra-violet band system of GeO, a survey was made of the band systems of the monoxides and monosulphides of the Group IV (*b*) elements which appear to be analogous to the "Fourth Positive" system ($A^1\Pi \rightarrow X^1\Sigma$) of CO and the well-known ultra-violet systems of CS and SiO. For SiS, the only molecule of the sub-group for which no data were available, the character and approximate position of the corresponding band system were predicted graphically.

Using heavy-current (3–5 amp.) discharges through a mixture of SiS vapour and argon in a tube of the type recently described by Pearse and Gaydon[2] and also in an all-silica tube, we have observed in the region λ2576–λ3876 a system of some seventy to eighty bands degraded to the red. The heads are approximately represented by $\nu_{\text{head}} = 35028\cdot5 + (512\cdot9u' - 2\cdot88u'^2 - 0\cdot006u'^3) - (749\cdot6u'' + 2\cdot58u''^2)$ where u is written for $v + \frac{1}{2}$. The rotational structure of the stronger bands in high dispersion appears to be of the well-known three-branch type given by a $^1\Pi \rightarrow {}^1\Sigma$ transition. That the lower state is the ground state of SiS is proved by our further observation of a few of the bands (about eight strong bands with $v'' = 0$ and 1) in absorption by SiS vapour at about 1000° C.

In the SiS discharge also are some seventy to eighty bands extending from λ3491 to λ6169, which are similar in appearance and distribution to bands in the longer-λ sequences of the above system. They appear to form part of another system, the upper and lower states of which are different from, but have vibrational frequencies of the same order as those of the ultra-violet system. The emitter may be SiS, which is expected to have triplet as well as singlet states.

The ultra-violet system of SiS is well developed also in a heavy-current discharge through Al_2S_3 vapour in a silica tube. In this source, however, the well-known $^3\Sigma \rightarrow {}^3\Sigma$ system of S_2 (of which there is, fortunately, no trace in the SiS discharge) is prominent, and the second set of bands cannot be detected.

Fluctuation Noise in Thermionic Valves

In a recent paper[1], I put forward the theory that the noise generated by a thermionic valve is alternatively (*a*) of the shot noise type if the valve anode current is temperature-limited, *or* (*b*) of the thermal or 'Johnson noise' type if the current is fully space-charge limited. (Contrast Llewellyn's theory that the noise in the presence of space-charge is the *sum* of shot and thermal noise, with a smoothing factor applied to the shot noise.) In the paper quoted, however, there was no quantitative treatment of the practical case of a valve which is partially space-charge limited, that is, does not correspond exactly to either of the simple states of temperature or space-charge limitation.

It has now been found possible to treat this practical case with moderate accuracy by dividing the current into two parts. Assuming the law of the valve under investigation to be known for the fully space-charge limited condition (for example, $i_a = bV_a^{3/2}$ for a diode), the proportion of the observed anode current which is fully space-charge limited can be deduced by comparing the slope of the measured i_a/V_a characteristic with the calculated value for an equal current with full space-charge limitation; when the current so calculated has been subtracted from the total measured current, the residue is current which is temperature-limited. The total noise output of the valve is then the sum of (*a*) the thermal noise in the measured resistance (calculated in accordance with the methods given in the paper already quoted), and (*b*) simple shot noise arising from the residual current which is temperature-limited.

This method has been applied numerically to two diodes, and it is hoped to extend it to triodes before full details are published.

Elastic Constituent of Rubber

IN a recent paper[1] K. C. ROBERTS has described the isolation from dried fresh *Hevea* latex of small quantities of a highly elastic substance which he has named caoutchol and to which he has ascribed the formula $C_{80}H_{130}(OH)_2$. This substance has been shown to possess the high degree of elasticity hitherto regarded as characteristic of rubber; the rubber hydrocarbon purified by its removal is comparatively non-elastic.

The X-ray photograph of freshly prepared caoutchol, unstretched, at room temperature (35° C.), shows certain sharply defined rings identical with those reported by W. H. Barnes[2] for 'frozen' rubber. Other rings, however, exhibit significant differences. At 700 per cent extension, caoutchol gives an X-ray photograph almost identical with that obtained from stretched, air-dried, fresh latex, the transition from the rings of the Debye-Scherrer diagram to the sharply defined spots of the fibre pattern being clearly visible.

The purified rubber hydrocarbon, to which Dr. Roberts has given the name caoutchene, does not show the sharply defined rings characteristic of caoutchol nor can it be extended sufficiently to give the fibre characteristic of stretched rubber. The X-ray evidence therefore supports the theory that the minor constituent caoutchol is the primary factor in the elasticity of rubber.

The detailed results of this work, together with further X-ray observations on derivatives of caoutchene and caoutchol, will be published elsewhere.

Food of the Partridge

JUST a quarter of a century ago I concluded an investigation on the food and feeding habits of the partridge, and my results were set forth in the *Journal of the Land Agents' Society* (June 1917), and in further detail in *Science Progress* (Oct. 1918). I found an examination of crop, intestine and stomach contents over a period of five years to "show that of the total bulk of food consumed 59·5 per cent. is vegetable matter and 40·5 per cent. animal matter. Of the former 53·5 per cent. consists of leaves, fruits, and seeds of weeds, 3·5 per cent. of grain, and 2·5 per cent. of miscellaneous vegetable matter. Of the animal matter, 23 per cent. consists of injurious insects, 3 per cent. of beneficial species, 4 per cent. of neutral species, 6·5 per cent. of earthworms, and 4 per cent. of slugs complete the summary." These facts were repeated in my work on "The Food of Some British Wild Birds" (1924–27).

In November last, Mr. A. D. Middleton and Miss H. Chitty published an interesting paper on this subject in the *Journal of Animal Ecology* (which I have only just seen), in which they state "Perhaps the most striking are the large quantities of green food eaten during the winter and spring months and the very low percentage of animal food. For some reason, partly due to the publications of Collinge, insects have for a long time been regarded as an important and even essential part of the food of partridges."

With all respect, as one who has devoted more than thirty years of his life to such investigations, I think I may say that Mr. Middleton and Miss Chitty have failed to realize one of the most important results of their work, namely, that since I carried out my investigation on the nature of the food of the partridge, in 1912 and 1913, this bird has changed its food habits, just as the rook and the starling have in that period. Like these authors, I chronicled exactly what I found in the stomach and intestines, they in the crops, and the two records show conclusively the change that has taken place. There can be little doubt that this change has not been beneficial to the partridge as a species, for, for some years past, the mortality due to strongylosis and coccidiosis and other causes have been enormous.

It is clear to me that here we have a very striking case of reduced vitality due to a change in diet, and it shows how important it is, as I have previously advocated, that from time to time all such investigations should be repeated, in order that the true economic status of any particular species of wild bird should be ascertained.

Cytology of Metamorphosis in the Culicinæ

A NUMBER of investigators[1] have distinguished two main types of larval insect tissue with respect to growth and metamorphosis. Many tissues grow by increase in cell size and undergo disintegration at metamorphosis, the corresponding adult tissue being formed from imaginal disks that were not functional parts of the larval tissue. The second class of tissues grow by cell division and multiplication, and are carried over, with or without modification, into the adult.

The epithelium of the larval ileum of *Culex pipiens* behaves in a manner intermediate to the two methods described above. Larval growth is accomplished solely by increase in cell size, and at metamorphosis the adult tissue is formed by the simultaneous division, reduction in size and increase in number of these same larval cells. In this case great increase in cell size is not accompanied by inability to divide or to undergo further differentiation.

These phenomena, first observed in *Culex pipiens*[2], have during the past year been found in the following other species collected in Maryland: *Culex apicalis* Adams, *C. territans* Walker, *Aedes canadensis* Theobald, *A. triseriatus* Say, *Orthopodomyia signifer* Coquillett, and *Anopheles punctipennis* Say. Metamorphosis of this type is probably present throughout the sub-family Culicinæ.

All seven species have a diploid number of six chromosomes. The following cytological peculiarities, first studied in *Culex pipiens*, have since been found in the other six species of mosquito: (*a*) increase in the chromosome number of larval cells, accompanying increase in size and apparently taking place within the resting nucleus; (*b*) multiple chromosome complexes of 192, 96, 48, 24 and 12 chromosomes appearing during the mitoses effecting metamorphosis, and showing a direct correlation between chromosome number and cell size; (*c*) prophase synapsis of high multiples of sister and homologous chromosomes with no formation of chiasmata.

Considerable indirect evidence favours the interpretation that these divisions are somatic reduction divisions. Decisive evidence is being sought by attempting to observe the process in the living organism.

Absorption of Growth-Promoting Substances by Cuttings

ABOUT two years ago a batch of leafless cuttings of *Bougainvillea* (var. Mrs. Louis Walthen) was received at these laboratories for propagation. They were planted in our usual propagators. The majority threw out small shoots but there was no callussing or root development. After eighteen months it was decided to try the effect of a proprietary root growth-promoting substance. The cuttings still alive were treated in the normal way, that is, by immersion of the basal ends in a dilute solution for eighteen hours. However, no callussing or rooting took place and it is assumed that this was due to lack of transpiration in the cuttings, which were leafless when treated.

Finally it was decided to try the effect of forcing the growth-promoting substance into the cuttings now almost exhausted of food reserves. The ends of the cuttings were cut off to expose fresh surfaces. The lower ends were submerged to a depth of one inch in the solution contained in a vacuum desiccator which was exhausted until a strong stream of bubbles emerged from the bottom end of each cutting. On breaking the vacuum the solution was forced into the submerged ends. Two or three months after replanting the cuttings, 90 per cent rooted and are now healthy plants.

The experiment was not planned as a test of the growth-promoting substance, but was made in a final attempt to save the last remaining cuttings of a variety new to Kenya. So striking have been the results that the suggestion is put forward that possibly failure to secure rooting with winter cuttings of deciduous plants after treatment with various growth-promoting substances has been due to non-absorption, or to the absorption of too little of the material by the leafless cuttings.

Probable Fossil Hail Impressions in Natal Coal Measures (Middle Ecca Series)

DURING the course of a geological survey of the Verulum district, Natal[1], some peculiar little depressions were noticed on the upper surfaces of freshly exposed slabs of lower Middle Ecca (Permian) sandy shales occurring in a small road-metal quarry situated on the main road between Verulum and Tongaat, a little north of the Shortlands Hotel. The depressions appeared to be confined to a single horizon which, owing to the lack of exposures, could not be traced beyond the confines of the quarry.

The depressions, which are circular to slightly elliptical in outline, are bounded by slightly raised edges. In size they are remarkably uniform, averaging about 14 mm. in diameter and 5 mm. in depth, while in shape casts showed that they are slightly assymmetric, the steeper sides being usually similarly orientated.

Specimens cut perpendicularly to the bedding revealed that the laminæ immediately under the depressions were arched down as though the latter had been caused by blows. Their casts in the overlying horizon were found to be slightly coarser grained than the bounding layers and invariably plano-convex in shape.

It has been indicated by Twenhofel[2] that the maximum depth of rain-drop impressions appears to be 3 mm. and their maximum width 12 mm. It would seem, therefore, that some other natural origin should be postulated for these depressions. Their character seems to suggest that they were caused by the impact of hailstones, since their relatively great depths in proportion to their diameters eliminates the possibility of their being splash impressions.

Twenhofel[2] also figures artificial hail-impressions in mud which are characterized by very steep sides and relatively great depths. Preliminary observations made during actual hailstorms and experiments made by dropping ice spheres indicate, however, that even in highly plastic muds, a layer of water only a few millimetres in thickness over the surface of the mud suffices to modify the effects considerably—shallower and more regular plano-convex depressions resulting. Futhermore, if the hail falls on exposed sand or sandy mud, shallower depressions result, provided that other factors such as the size, shape and velocity of the stones remain constant. In the case of only slightly plastic moist sands, secondary minor depressions, either adjacent to or overlapping the major direct ones, are formed owing to the bouncing of the hailstones.

In the present area the unconsolidated material was a sandy mud which, as fossil rain-prints, etc., noted in other portions of the Verulum area indicate, was on occasion exposed to sub-aerial conditions. Incidentally, depressions identical in appearance with those on the sandy shales were produced by dropping small rounded hailstones from a height of 15 ft. into a sandy mud which was covered by a 2 mm. film of water.

With one exception[3], these would appear to be the first impressions tentatively attributed to the action of hail which have been recorded from the whole geological column. The re-examination of reported 'rain print' localities in the light of experimental evidence would, however, appear to be desirable.

Heavy Electrons in Cosmic Rays

A LETTER under this title appeared in NATURE of April 16. In the table on p. 685, the values of the momentum of the particles *a*, *b*, *c* and *d* (col. 4) should have been given as 69, 110, 95 and 73 respectively, instead of 65, 107, 86 and 67. The errors arose from an unnecessary alteration of the completed table, under the impression that some early preliminary data had been quoted. The masses in the last column correspond to the correct values of the momentum. We would also add that the results of Nishina and his collaborators, referred to in the above letter are in accord with ours for particulars *a*, *c* and *d* rather than *b*.

Illusion of Convergent Beams of Light

'CONVERGENT' beams similar to those reported by J. J. Hopfield[1] and A. C. Klebs and others[2] can be observed near lighthouses.

The effect was frequently observed by me in Scheveningen in Holland and corroborated by others, from a road running parallel to the shore between the lighthouse and the sea.

At evenings when in a slight haze the rotating beam of light from the lighthouse could be followed to the opposite horizon, the light beams seemed to converge towards the opposite horizon in such a way that a rotating beam of light appeared to be issuing from this horizon opposite the lighthouse, giving a strong impression that a second lighthouse, issuing a rotating beam of light, was out at sea beneath the opposite horizon.

The phenomenon is different from those observed with sunbeams in so far as the beams from the lighthouse are really diverging, practically from a nearby point, whilst the sunbeams are parallel. It is interesting that similar 'convergent' beams can be observed in both cases.

Points from Foregoing Letters

THAT yeast cells, transported by wind, may be carriers of various viruses, including that responsible for foot-and-mouth disease, is suggested by Prof. R. C. McLean, who points out that methods of acquiring immune strains of animals might be the only way of preventing the disease.

The discovery of a complete right jaw-bone, with several teeth, attributed to *Australopithecus*, is reported by Dr. R. Broom. The reconstructed face agrees fairly closely with that of the chimpanzee but the teeth are human. The author suggests that man may have arisen from *Australopithecus* by a mutation resulting in a large brain.

A method of gilding copper by applying a melted gold-copper eutectic (80 per cent gold, 20 per cent copper) which was apparently used by the pre-Columbian Indians is described by P. Bergsøe. The alloying was used, apart from purposes of decoration, to increase the hardness of certain articles, such as fish-hooks.

A colorimetric method for the estimation of nicotinic acid—the probable pellagra preventive factor—has been developed by M. Swaminathan. The nicotinic acid content of twelve common foodstuffs, as determined by the method, is also given. Values ranged from 1·48 mgm. per cent for maize up to 62·50 mgm. per cent for dried brewer's yeast.

By heating alloys of copper or silver containing a small percentage of aluminium or beryllium in an atmosphere of hydrogen and water vapour, under controlled conditions which allow selective oxidation, G. J. Thomas and Laurence E. Price have obtained protective films of alumina and beryllia which render the metals almost immune from tarnishing and scaling. The authors explain how they were led to their experiments by theoretical considerations on the electrical conductivity of surface films.

Dr. F. J. Stare, E. S. Gordon and M. J. Musser have observed that succinic acid does not catalyse the aerobic respiration of skeletal muscle tissue obtained from patients with myasthenia gravis and progressive muscular dystrophy, and that it is oxidized only to a slight extent. The usual catalytic effect was observed with normal human muscle. The results are of interest as they suggest that disturbances in the succinic acid cycle may be associated with these muscular diseases.

A graph showing the activating effect of synthetic vitamin B_1 upon the production of carbon dioxide through the action of cocarboxylase is given by Dr. S. Ochoa. The pyrimidine group of the vitamin appears to be responsible for activation, and previous views on cocarboxylase action may have to be revised.

Dr. E. Bergmann and Prof. R. Samuel advance a theory of photodecomposition of organic molecules according to which two bonds are fissured simultaneously, not by the splitting of two single bonds, but by a transition of the molecule to a repulsive state, which is produced by the repulsive character of the s^2 group of electrons of the central atom.

R. F. Barrow and Dr. W. Jevons announce the observation and vibrational analysis of the predicted ultra-violet band system of SiS, which corresponds to the "Fourth Positive" system of CO.

D. A. Bell states that the total noise output of a radio valve can be considered as made up of (*a*) the thermal noise in the measured resistance and (*b*) simple shot noise arising from the residual current, which is temperature-limited. This view has been applied to the case of diode valves.

X-ray studies of rubber constituents show, according to Dr. T. C. Roberts, that the highly elastic caoutchol, when stretched, gives X-ray patterns similar to those of stretched raw rubber. The author considers that this minor constituent of rubber is responsible for its elastic properties, rather than the major constituent, caoutchene, which does not show such an X-ray pattern.

Prof. C. A. Berger reports a new method of insect metamorphosis found in seven species of mosquitos from four genera. Cytological peculiarities present throughout the group throw new light on chromosome pairing and the origin of polyploidy.

Woman's Status in Manam, New Guinea

MISS CAMILLA H. WEDGWOOD opens a study of women in Manam, an island about ten miles off the north-east coast of New Guinea, with an examination of the status of the women in Manam society (*Oceania*, 7, 1937, 4: Sydney Univ. Reprints, ser. 12, 2, 15–18, 1937). The belief that women in the islands of the west Pacific have a very low status has some support; but it is not possible to make any statement which will be valid for the whole. In Manam the social differentiation between the sexes is marked in almost every department of daily life. The women have their distinctive dress and modes of doing their hair, their distinctive occupations, and even their way of sitting and carrying their loads. Any departure from these distinctions provokes comment or ridicule. At gatherings in which both men and women are present the sexes sit apart and carry on conversation within the separate groups. In the economic sphere the differences between men and women are very sharply emphasized; but there is no ritual prohibition against a man doing a woman's work, or *vice versa*. For a man to fill and carry the drinking vessels from the water-hole, however, or to boil food in a pot, would be considered somewhat degrading for him; and the women would be as ready as the men to laugh at him for doing this; but he breaks no taboo thereby. It is considered equally ridiculous and wrong for a woman to ape a man; but there is nothing reprehensible for a woman to be skilled in some of the crafts which are usually known only to men. On the contrary, such a woman is often respected for her skill. The men generally assume that they are superior to the women, who are debarred from taking part in the sacred rites of the men, a privation justified by their inferior worth. Their interests, conversation and quarrels are trivial, when compared with the 'important' matters men discuss. To a great extent, the women echo the opinions of the men concerning their sex.

The Mammals of Ireland

SINCE William Thompson's description of the mammals of Ireland was published in 1856, no comprehensive account of the group has appeared. In the twenty-second report from the Fauna and Flora Committee, C. B. Moffat has brought the subject up to date by gathering together the scattered information which has accumulated in three quarters of a century, and commenting upon the present status of the 55 representatives of the Irish mammalian fauna (*Proc. Irish Acad.*, 44, B, 61; 1938). The greatest change occurs in the Cetacea, where 10 species are recorded as new to the fauna. Of land mammals Ireland possesses only 33, in contrast to the 54 which are present in Great Britain. The most noticeable blanks occur amongst the rodents, where voles are unrepresented; the insectivores, which include only the hedgehog and the lesser shrew; and the bats. Additions to the fauna include the Egyptian mouse (*Mus musculus orientalis*), the tree rat (*Rattus rattus frugivorus*), and the deliberately introduced grey squirrel, which is well established in Co. Longford. The Irish stoat and mountain hare are now regarded as specifically distinct from the British forms. The author notes that since the European War marked changes have occurred in the numbers of some members of the fauna: rabbits and mountain hares have increased, as well as some of the beasts of prey such as the fox and badger, while others, like the hedgehog and the red squirrel, appear to be declining. The latter, although once a native of Ireland, is now represented only by descendants of introduced individuals.

Nest-building of the Bush-tit

IN an account of the behaviour of the Californian bush-tit (*Psaltriparus m. minimus*) Alice Baldwin Addicott gives some interesting details about nest-building (*Condor*, 40, 49; 1938). The completed nest is a delicate suspended structure with a hood, very like that of the European penduline tit. The first step in the construction of the nest is the weaving of a horizontal rim, held together by spider's web and attached between a forked branch or two adjacent twigs. From the rim a loose bag is generally suspended, built by the birds as they perch upon the rim and work, head downwards, at the inside surface, to which strengthening materials are added. The last process is the construction of the hood and of the final side entrance which supersedes the first rim opening. The nest is made of mosses, lichens, oak leaves and spider's web, so blended that externally the structure is inconspicuous in its surroundings; the inside is lined with spider's web, down or feathers. The time taken in building varied from 13 to 51 days, the average being just over 33 days, but it was noticeable that nests built later in the season were more rapidly completed than early nests, and the opinion may be hazarded that, since many pairs nest a second time, the increased speed of construction was due to practice.

Marine Plankton Animals as Indicators of Water Movements

THE belief that certain plankton animals may serve as indicators of water movements has long been held by some marine biologists; but it was not until the publication of a paper by F. S. Russell in 1935 (*J. Mar. Biol. Assoc.*, 20, 309–331) that their value for this purpose in British waters was clearly demonstrated. At the western entrance to the English Channel—the area studied by Russell—the most useful indicator animals were found to be certain members of the chætognath genus *Sagitta*, three species of which occur in that locality. Following upon Russell's researches, J. H. Fraser studied the occurrence and distribution of chætognaths in Scottish waters in 1936 (*J. Conseil Perm. Intern. pour l'Explor. de la Mer*, 12, No. 3, 311–320; 1937). Six species or sub-species of *Sagitta* and one species of *Eukrohnia* were collected, all of which revealed well-marked correlations with different water masses. *S. setosa* was distributed over the whole of the North Sea and extended as far as 61° N. except where there was some oceanic influence; *S. elegans* was found to belong to mixed oceanic and coastal waters (cf. Russell's 'western water'); *S. serratodentata* was more truly oceanic; *S. maxima* belongs to the deeper oceanic waters (below 600 metres) and is brought into shallow water by upwelling along the edge of the continental shelf; *S. hexaptera* is typical of the epiplankton of tropical and sub-tropical regions, but a few individuals were taken in the Faroe-Shetland Channel, probably indicating an influx of some warm Atlantic water. Both this species and *S. maxima* quickly die on reaching Scottish waters. *E. hamata*, like *S. serratodentata*, is an oceanic form of more general distribution but belongs to a slightly deeper habitat. This work on Scottish chætognaths, although only a preliminary survey, is a useful contribution to our knowledge of plankton animals as indicators of water movements. Analyses of additional collections made over a number of years in the same region are contemplated and should furnish further information of great interest and value.

History of the Peach

THE community of gardeners has to thank Mr. E. A. Bunyard for many scholarly dissertations upon the histories of various cultivated plants. Peaches and nectarines have lately claimed his attention (*J. Roy. Hort. Soc.*, 63, Parts 3 and 4, March and April 1938). The first mention of the peach in literature is, according to Bretschneider, contained in a Chinese manuscript of 551 B.C., and there can be little doubt that China was the original home of this fruit. The Romans probably obtained peaches through Persia, and peach stones of present-day size were excavated from Pompeii. Representations upon frescoes in that city's ruins also show fruits equal in dimensions to those of modern times. The peach was known in England during Anglo-Saxon times, and became somewhat notorious in 1216, when King John died "from a surfeit of peaches and ale". Thomas Rivers of Sawbridgeworth, his son and grandson, together introduced more than twenty-seven new varieties of peaches and nectarines, whilst a particularly early fruiting type was developed in America. Mr. Bunyard also deals in detail with the cultivation of the peach and nectarine.

Artificial Doubling of Chromosomes

A. F. Blakeslee and A. G. Avery have used the alkaloid colchicine to bring about doubling of the chromosomes of certain plants. A short paper in the *Gardeners' Chronicle* of April 16 outlines the process, and cites further papers where greater detail is published (for example, *J. Hered.*, 28, 392–411; 1937; or U.S. Dept. Agric. Year Book, separate No. 1605, 1–35; 1938). Solutions of the amorphous product in strengths varying from 0·0004 per cent to 0·4 per cent have been used. Seed of *Datura*, for example, was soaked in a 0·2–0·4 per cent solution for 4–10 days before planting. Plants grown from treated seed are often at first stunted and malformed, and it is only in the succeeding generation that individuals with doubled chromosomes may be expected. The discoverers of this treatment have shown considerable restraint in their interpretation of the experimental results, but great possibilities may be envisaged when more detail is made available.

New Zealand Earthquake of 1934

THE Pahiatua earthquake of March 5, 1934, is described by Mr. R. C. Hayes in *Bulletin* No. 122 of the Wellington Dominion Observatory. The region most severely shaken lay along the east coast of the North Island, about fifty miles south of Hawke's Bay, and the shock was felt at Dunedin, 460 miles from the epicentre, or to about the same distance as the great earthquakes of 1929 and 1931 were felt. So far as can be judged from the records of the seismographs that were not dismantled by the shock, the epicentre was submarine, in lat. 40° 57′ S., long. 176° 48′ E., or about thirty miles east of Castlepoint. The focal depth is uncertain, but probably lay between 20 km. and 40 km.

New Radioactive Silver Isotope

RECENT investigations on the artificial production of radioactive silver isotopes have led to the discovery of four more isotopes, in addition to those with half-life periods of 2·3 min. and 23 sec., respectively, discovered by Fermi and his co-workers. ^{106}Ag occurs in two isomeric forms, one of which emits positrons, and has a half-life period of 24·5 min., whilst the other gives electrons, and has a half-life of 8·2 days. Both are obtained, with others, by bombarding silver with rapid neutrons, the process being ^{107}Ag $(n, 2n)$ ^{106}Ag. ^{108}Ag has a half-life of 2·3 min., ^{110}Ag one of 23 sec., ^{111}Ag one of 7·5 days, and ^{112}Ag one of 3·2 hours. ^{107}Ag and ^{109}Ag are stable isotopes. Further experiments by H. Reddemann and F. Strassmann (*Naturwiss.*, 26, 187; 1938) on the bombardment of silver foils in paraffin with slow neutrons for long periods (2 months), have indicated the existence of a new active isotope, with a half-life as long as 190 ± 40 days. That the activity was indeed due to silver was confirmed by chemical separation. It is probable that the isotope is produced by a (n, γ) process, and may be an isomeric nucleus of atomic weight 108 or 110.

Field Due to Two Nuclei

IN wave mechanics one often meets the problem of an electron acted on by two centres of force. This is the fundamental problem of molecular forces or of chemical valency, and also arises in the study of the spectra of atoms such as helium. A summary of the present state of the problem and a new contribution to the subject are given by E. A. Hylleraas (*Ann. de L'Institut Henri Poincaré*, 7, 121; 1937). The usual approximate treatment replaces a non-central and non-statical field by the central statical field which is the average of the true field. This works fairly well for some purposes, but is unsatisfactory for the calculation of the polarization produced by an external electron. For molecules, there are two methods often employed. Heitler and London form the characteristic functions for a molecule from those of isolated atoms, while the other method uses the functions for an electron due to two nuclei. The first method works best for large atomic distances, the second for small. For moderate distances both are unsatisfactory unless certain corrections are made. Dr. Hylleraas treats in detail the simplest case, where the two centres have equal charges, as in the hydrogen molecule-ion. The wave equation separates into two, the interior and the exterior equation. A new method of treating these is suggested, which should lead to a complete solution in the exterior case, but further calculations are required before its value in the interior case can be estimated.

Chemical Reactions Involving Solids*

PHYSICAL BASIS

INTRODUCTORY papers by Profs. N. F. Mott (Bristol) and J. C. Slater (Cambridge, Mass.) dealt with the motion of electrons in polar salts. Electrons can be set free by the absorption of light or by the heat motion of the atoms of a crystal; however, the absorption of light will not necessarily free an electron; an atom of the crystal may be raised merely into an excited state, without the electron being free to move far away from its original position. An excited atom in a crystal has been termed an 'exciton'; an exciton can move a certain distance through the crystal by transferring its energy from atom to atom, before the energy is all dissipated. The various types of lattice imperfection at which an electron can be trapped were also discussed.

Papers by Prof. J. D. Bernal (London), Prof. G. Hevesy (Copenhagen), H. A. C. McKay (London), Prof. C. Wagner (Darmstadt), Prof. W. Jost (Hanover), Dr. T. P. Hoar and Dr. L. E. Price (Cambridge), and Dr. J. A. A. Ketelaar (Leyden), dealt mainly with the transport of atoms and ions through solids. Experiments on self-diffusion in metals were described, using natural and artificial radioactive materials as indicators. A hypothesis was advanced to account for the small values of the coefficients of self-diffusion, compared with the coefficients of diffusion of one metal into another. Ionic conductivity and diffusion in solid polar salts were discussed in the light of the theory that there exist in a polar salt in thermodynamical equilibrium a certain number of vacant lattice points and a number of ions in interstitial positions. Experimental and theoretical methods of estimating the activation energies necessary for the formation of these configurations were described. Finally an account was given of the behaviour of salts of very high conductivity, for example, α-Ag_2HgI_4.

PHOTOCHEMICAL PROCESSES

A number of papers dealt with photochemical reaction in solids. Dr. R. Hilsch and Prof. R. W. Pohl (Göttingen) demonstrated a beautiful experiment in which a transparent crystal of potassium bromide containing KH in solid solution is coloured blue on exposure to ultra-violet light, the well-known *Farbzentren* being formed. The efficiency of the photochemical reaction falls rapidly, however, as the temperature is lowered. Prof. J. Eggert and M. Biltz (Leipzig) described experiments on the sensitivity of the silver bromide photographic layers; they considered that *Störungstellen* in the halide grains have two functions: to serve as nuclei for the formation of the latent image, and, for wave-lengths greater than 500 mμ, to make possible the absorption of light.

Papers by Dr. C. F. Goodeve and J. A. Kitchener (London) dealt with photosensitization by solids, and by Prof. W. Reinders and Dr. M. C. F. Benkers (Delft) with the physical development of the latent image. Dr. Lüppo-Cramer (Jena) contributed a paper on photographic sensitivity, and Prof. F. Weigert (Glasgow) on a new time phenomenon in photographic emulsions.

THERMAL DECOMPOSITION AND THE DETONATION OF SOLIDS

Prof. S. Roginski (Leningrad), in a classification of the reactions involving solids, showed that sometimes the chemical and sometimes the crystallization steps determine the course of the reaction. Near equilibrium and when $Q + E$ is small or negative, the processes are governed by crystallographic factors, the rate of reaction in such cases being proportional to the surface area of the grains. The decomposition of hydrates and mercuric oxide (HgO) are good examples of this type. On the other hand, when $Q + E$ is large and the processes are irreversible, the chemical reaction may take control and the reaction penetrate the lattice in an irregular fashion, giving rise to chain reactions. F. R. Meldrum (Bristol) gave an account of the decomposition of nitrogen iodide, which may be of this latter type.

The conditions under which nuclei form and grow on the surface of crystalline solids were dealt with by Prof. W. E. Garner (Bristol), and a distinction was drawn between endothermic and exothermic changes. There is lattice penetration in certain explosives, for example, mercury fulminate, and it is found generally that in the exothermic class, $dp/dt = kp^n$, where $n = 0{\cdot}8$–1, is obeyed instead of the 2/3 power law. This indicates that these reactions are chain reactions, it being maintained by some investigators that the chains are structural in character and by others that they are analogous to the chain reactions occurring in the combustion of hydrocarbons (Semenoff).

A number of phenomena arise when the rates of formation of the new solid phases are slow. Prof. J. Zawadski and Dr. S. Bretsznajder (Warsaw) showed that spurious equilibria (sorption equilibria) are found in the case of zinc and cadmium carbonates which are due to the slow rate of crystallization of the oxides and carbonates. In the case of hydrates, two factors are involved: (1) the retardation of the rate of reaction by water vapour is greater when the new solid phase is amorphous than when it is crystalline; and (2) water vapour catalyses the crystallization of the new phase (Volmer). Dr. J. Colvin and J. Hume (Leeds) discussed the application of these principles to the appearance of metastable hydrates during dehydration, and showed that the tri-hydrate of copper sulphate is produced when conditions are favourable to the crystallization of this phase. They also gave an account of the Topley-Smith effect with $Mn(COO)_2 2H_2O$, where a minimum in the rate of dehydration occurs at a water vapour pressure of 0·1 mm. In the course of the discussion, it was agreed that the explanation of this effect given by Volmer, which was based on the above principles, is substantially correct.

---

* Report of a General Discussion, arranged by the Faraday Society, held in the University of Bristol on April 11–13.

The thermal decomposition of solids of the explosive class passes into a linear propagation of the reaction or deflagration under certain conditions, and the cause of this transition was ascribed to the simultaneous decomposition of a small number of adjacent molecules (Prof. W. E. Garner and Dr. H. Muraour (Paris)). It was pointed out that the linear propagation can arise under conditions where there is a negligible self-heating of the crystals and therefore that the deflagration must be due to some localized event. Dr. W. Taylor and A. Weale (Stevenston), who have studied the initiation of detonation by mechanical shock, put forward a tribo chemical theory of the origin of the detonation wave, ascribing to the action of friction the activation of a number of adjacent molecules which serves as the centre from which detonation can be initiated.

As Muraour pointed out, although the thermal decomposition can pass into deflagration, it is not possible in all cases for deflagration to pass into detonation, and Taylor and Weale ascribed this to the necessity for a critical stress which must be set up before detonation can occur. This critical stress varies in magnitude from case to case, being very small for explosions of the initiating class but possessing a high value in the case of typical high explosives. This stress cannot arise in all cases from the thermal decomposition but can be brought about by initiation with a more sensitive explosive. The view was expressed in the discussion, in which M. Polanyi, W. Jost, W. Payman and J. D. Bernal took part, that under the high pressures in the detonation wave, 350 tons/in.^{2} and more, the molecular compression would be sufficiently high to cause chemical reaction, the effect of the stress being such as to cause the disappearance of the energy barrier separating the reactants from their products. No general conclusion was reached on this matter, it being considered that other factors such as temperature may play some part in the propagation of the wave. Dr. T. Carlton Sutton (London) brought forward evidence in the case of tetryl that the heat of detonation increases step-wise with increasing density of loading.

LAYER LATTICES IN SOLID CARBON

The unique electronic structure of the carbon atom which is responsible for its extensive organic chemistry also confers upon solid carbon peculiar properties of considerable interest and fundamental importance. The advent of X-ray methods of studying the solid state has made possible a much deeper insight into the chemical nature and reactivity of black carbon, and the papers discussed in the section of the discussion dealing with this aspect suggested that the near future will witness a rapid development of this solid phase chemistry, which originated with Fredenhagen's discovery of the alkali-graphites some ten years ago.

Already the list of inter-layer lattice compounds is of considerable length, and although the nature of some of the compounds is still somewhat obscure, their further study is likely to give results of considerable importance. Prof. U. Hofmann (Rostock) described the formation of salts of graphite and strong acids. The peculiar step-wise manner in which these salts decompose (similar to the manner in which C_8K passes into $C_{16}K$) suggests that there is a fundamental electronic connexion between the layer planes of the graphite crystal lattice. Prof. O. Ruff (Breslau) put forward certain suggestions concerning the structure of 'amorphous' carbon and discussed the reactions of carbon with oxygen, fluorine, carbon dioxide and with metals. He also exhibited specimens of graphite monofluoride prepared by himself and Bretschneider and demonstrated the decomposition of the substance on warming. The reaction (*Verpuffen*) was very reminiscent of the decomposition of graphitic oxide. Prof. H. L. Riley (Newcastle-upon-Tyne) directed attention to the abrupt changes which occur in the properties of the products of carbonizing various organic substances at temperatures in the neighbourhood of 700° C. He discussed particularly the susceptibility of various carbons to oxidation to chromic-phosphoric acid and the changes which occur in the strength of coke during carbonization. Dr. H. Thiele (Kiel) discussed the oxidation of black carbon in various electrolytes at room temperature, and demonstrated the swelling of a graphite electrode when anodically polarized in concentrated sulphuric acid, and also the peculiar crackling which occurs when a hard carbon electrode is treated in a similar manner. He referred to the various stages in the oxidation: (1) primary oxide, (2) swollen oxide, (3) blue graphitic oxide and graphitic acid and also humic acid.

The problems connected with the kinetics of carbon combustion are likely to become less obscure as our knowledge of the chemical nature of black carbon increases. In spite of extensive experimental work, the exact mechanism of carbon oxidation is still obscure. Prof. V. Sihvonen (Helsingfors) discussed the influence of keto- and ketene groups and of adsorbed molecules and ions and the mechanism of carbon oxidation. Basing his views on extensive experimental work on the reduction of carbon dioxide, adsorption of oxygen, combustion in oxygen, effect of water vapour and the anodic oxidation of carbon both in electrolytes and in the gas phase, he advanced comprehensive theories as to the mechanism of the breakdown of the carbon lattice. Dr. Lothar Meyer (Höllriegelskreuth, near Munich) described some of his ingenious experiments on carbon combustion at low pressures. The technique employed, following the static experiments of Langmuir, consists in streaming the oxidizing gas at a pressure of a few thousandths of a millimetre of mercury, at a high velocity, over a carbon filament heated electrically, so reducing considerably the chances of secondary reactions occurring. The results obtained with oxygen, carbon dioxide, and water vapour were described. The part played by surface oxides in the oxidation of carbon was discussed by Dr. R. F. Strickland-Constable (Oxford). Although the exact nature of the oxide is still uncertain, there appears to be little doubt that some form of solid oxide plays an important intermediate part in carbon combustion. The views of Rhead and Wheeler put forward twenty-five years ago, and the recent views of Eucken on the mechanism of carbon combustion, support this idea. Strickland-Constable also described experiments on the oxidation of carbon in nitrous oxide. J. D. Lambert (Oxford) discussed briefly the effect of certain metals on the oxidation process.

The paper by Prof. E. Berl (Pittsburgh) on the formation and properties of activated carbon was taken as read. Only a very limited time remained for discussion.

Dominion Tributes to Lord Rutherford

TRIBUTES to Lord Rutherford continue to appear, written in many cases subsequent to the numerous appreciations in NATURE. Prof. T. H. Laby, professor of natural philosophy in the University of Melbourne, has published an article in the January number of the *Australian National Review*. Dr. C. M. Focken, lecturer in physics at the University of Otago, N.Z., has given a good summary (19 pp.) of Rutherford's life and work (Otago: N.Z. University. London: Whitcombe and Tombs, Ltd.). Dr. E. Marsden, now Director of the New Zealand Department of Scientific and Industrial Research, has written an interesting account of Rutherford's origin and youth in the *New Zealand Railways Magazine* for January and February, 1938.

The chief feature of these contributions is the insistence on the great benefits to the Dominions of Rutherford's visits and influence. Prof. A. Norman Shaw, of McGill University, has already pointed out that physics acquired a new status in Canada dating from that period when Rutherford 'set the St. Lawrence on fire' at the beginning of the century. During the visit of the British Association to South Africa, Rutherford spoke at several of the colleges, and the gratitude conveyed to him always expressed fresh interest and stimulation. In Australia and New Zealand his lecture tours were semi-regal, and Rutherford endeavoured in vain to curb the enthusiasm which would manifest itself in functions, students dragging his car, and even mayors and brass bands. The fact is that wherever he went—Europe, America or the Antipodes—he was one of Great Britain's best ambassadors.

Rutherford was aware, from personal experience, of the difficulties which most physicists have to face in working in the Dominions, sometimes rather isolated, with a shortage of co-workers to discuss developments, and with delay in acquiring information and delay in publication of results.

As Prof. Laby writes: "Although he left New Zealand as a young graduate, Rutherford never forgot his native land, and he rendered it many scientific services. This attitude was expressed, too, in the numerous connexions which he maintained with physicists in the Dominions: the many helpful letters which he wrote to them must have been no small tax on his energies. His experience in Canada, his visits to Australia, New Zealand and South Africa, gave him a quite rare perception of the difficulties of scientific work in the Dominions. He went to great pains to accept in his laboratory research students from the Dominions, and few were so quick to recognize in them real ability, if they possessed it, than he. . . . It is conventional to speak of the loss which a man's death creates, but it is no mere tribute of that kind to say Rutherford's death is a very real loss to physics in the Dominions."

So, too, Dr. Focken: "Although he was essentially modest and unassuming, his dominating presence commanded success. In view of his tremendous energy and blazing intellectual fire, it is not at all surprising that he got things done. . . . It is related that his students after a period of fear, learned to love and respect him. His enthusiasm infected them. Once a day he walked round the whole laboratory to talk to each student and discuss difficulties which had arisen and possible lines of advance in the student's research. He spoke of his forty or fifty students as his family, to whom he acted as 'father, grandfather and mother'. He was always pleased to take into his laboratory any young men from the Dominions who had had proper training, provided he had the accommodation. At one time he had so many of these students that he could not accept any from foreign countries. I recall his generosity in offering to allow me to work in his laboratory for a brief period at a time when he had many other applications from students willing to stay longer. Just as generations of overseas students at Oxford took delight in the open house kept on Sunday afternoons by Sir Charles and Lady Sherrington, so at Cambridge, students who attended the Cavendish Laboratory recall with great pleasure the informal tea parties in the Rutherford home."

Dr. Focken also mentions several interesting facts relating to Rutherford's early life which are not well known in Great Britain. His father, James Rutherford, was born a century ago in Perth, Scotland, and was taken by his parents to New Zealand while still a child. He became a wheelwright like his father and in 1866 married Martha Thomas. Ernest Rutherford was the fourth child of twelve and was born at Nelson on August 30, 1871. The family afterwards moved to Havelock, twenty-five miles east of Nelson and worked "an outback farm". From the age of eleven to sixteen, Ernest attended the Havelock school under Mr. Jacob Reynolds and won a provincial scholarship tenable for two years at Nelson College. Here he won many prizes, became dux of the College and gained a Junior University scholarship at Canterbury College, Christchurch. In 1893 he took his M.A. degree with first-class honours in mathematics and physics and next year was awarded an 1851 Exhibition Science scholarship with which he entered Cambridge in 1905. At Christchurch under Prof. Bickerton he constructed a magnetic detector of wireless waves, took a prominent part in debate and as a forward in the football team. According to a fellow pupil at Nelson and Christchurch, Mr. F. Milner, who contributes a foreword to the pamphlet, "whatever Rutherford did as a student he did thoroughly".

Dr. E. Marsden was one of the distinguished band of research students working at Manchester with Rutherford: "Geiger and Marsden made the very striking observation that some of the particles incident on a sheet of matter have their direction changed to such an extent that they emerge again on the side of incidence." ("Radiations from Radioactive Substances", p. 191.) This result started Rutherford on his successful voyage to the nucleus!

Marsden accompanied Rutherford on his last tour in New Zealand and made all arrangements for travel, meetings and lectures. He has written a good account of Rutherford's youth and given an appreciation of the enormous influence his life and work, his visits and lectures have had on the people of New Zealand.

Mr. R. M. Laing has contributed a brief article to *To-morrow*, a New Zealand independent fortnightly (Nov. 10, 1937).

The *Nelsonian*, the magazine of Rutherford's school, Nelson College, has collected notices and published a photograph of the old Rutherford home since demolished. One of the Houses at Nelson College is now known as Rutherford House.

Dr. C. M. Focker is also preparing a full bibliography of the publications of Lord Rutherford to be given in the *Transactions of the Royal Society of New Zealand*. The list is still incomplete, but the present number of books, letters and articles has already reached a total of some two hundred and sixty. It will be a valuable index of Lord Rutherford's activities.

The Assessment of Nutrition

IT is not often that a single problem is, at one time, and without deliberate co-ordination, studied by medical men, scientific workers and sociologists. This is the case with the 'assessment of nutrition'. Everyone who is interested should read a contribution* which both shows how urgent the problem is and (by implication, since the author tactfully understates his case) indicates possible modes of solution. Everyone should also read the discussion which follows the paper.

Mr. Huws Jones defines the problem : To discover undernourished children that they may be fed. There is reason to believe the methods in use are not discovering them all. Three possible improvements are suggested ; more frequent detailed medical examination, frequent rapid survey to select cases for detailed examination, or the use of a physical yardstick to select cases for detailed examination. Since questions of finance exclude the first suggestion (yearly examination of all children would mean trebling the number of school medical officers), and the second is not considered likely to be useful, attention is concentrated on the third.

The object of the inquiry was to show whether any system of physical measurements can be used to avoid unnecessary extension of medical examination, to select probable cases for the decision of the medical officer. School children were therefore medically examined and carefully measured. Children from the same school were examined by the same doctor on two occasions ; the same children were examined by different doctors ; the doctors "were urged to take as much time as they wanted over the assessment of each boy". Finally, the grading of the children by physical measurement and by medical opinion was compared.

The comparison showed that the percentage of children graded by medical examination as subnormal increased steadily from good to poor schools ; that height and weight, at each age, improved with social class ; that of children graded medically in the same nutrition class those in better schools were taller and heavier than those in poorer schools, and that height and weight in all classes of school improved with nutrition class. Nutrition grades, as determined by medical examination, "are distinguished best by weight, then by chest, and finally by height". But no combination of measurements could be found which could be used to pick out exactly the same children as the medical officers would select as a result of their examination.

The discussion is illuminating. Dr. Magee ignored the economic reason for seeking a time-saving substitute for clinical examination and wished to combine anthropometric with clinical examination and even add on physiological tests. Dr. Glover, of the Board of Education, cheerfully delivered himself into the hands of his critic on two counts, first that the discrepancies between the assessments of the different medical men could be explained as due to borderline cases, and second that the judgment of "teachers, school nurses, school attendance officers and others in regular contact with the children . . . could go far towards filling any gaps left by clinical assessment".

From the former of these suggestions, Mr. Huws Jones deduced that, in some areas, more than half the children examined were on the borderline between satisfactory and unsatisfactory nutrition, which makes the published reports of the Board seem "Too rosy". In view of the second, he wondered what need there is to employ medical men at all for this purpose if teachers appear to be so successful in picking out children who escape the doctors' scrutiny.

Dr. Daley suggested that the important thing was, not the anthropometric measurements at a given moment, but periodic measurements to show rate of growth.

Apart from the general conclusion that physical measurements give an index "at least as satisfactory as a careful and complete clinical examination", the issue is left in doubt. Indeed, Mr. Jones himself questions whether the best index he found (Tuxford's) can be regarded "as a satisfactory measure of nutrition". But, if the problem be accepted as originally enunciated, namely, to discover undernourished (that is, underfed) children in want of more food, then, on analogy with animal husbandry, physical measurements are the simplest and only reliable criteria. If, on the other hand, as appears from several parts of the discussion, something more difficult and subtle must be read into the problem, which becomes a complicated mixture of questions of disease and *mal*nutrition, as well as underfeeding, then the role of the doctor appears to be to select from amongst those shown by physical measurement to be below an accepted standard : (*a*) those whose condition is referable to any detectable disease condition not nutritional in origin ; and (*b*) those suffering not from gross lack of food, but from some particular deficiency. The first would receive appropriate treatment and all the others would be fed ; unless, of course, as Mr. Jones rationally suggests—and his study has given a general indication in favour of this solution—all the children from poor families are fed.

---

* Jones, R. H., "Physical Indices and Clinical Assessments of the Nutrition of Schoolchildren" (with Discussion), *J. Roy. Statist. Soc.*, 101, 1-52 (1938).

Science News a Century Ago

Thomas Andrew Knight, F.R.S., 1759-1838

On May 11, 1838, Thomas Andrew Knight, the plant physiologist and horticulturalist, died in London at the age of seventy-nine years. Born at Wormsley Grange near Hereford on August 12, 1759, he entered Balliol College, Oxford, in 1778, and being in possession of ample means was free to follow his own inclinations. His physiological investigations began with inquiries as to the circulation of sap, on which it has been said he "did much that was not only instructive for the time", but "was destined to remain with little modification among the fundamental facts of science". His most important work related to the growth of plants and their environment. In his study of the germination of seeds he used a revolving water-mill wheel on the edge of which he placed the seeds. He found that the shoots, no matter how they were pointed at first, gradually turned their points outwards from the circumference of the wheel, while the radicles grew inwards. In 1795 he read a paper to the Royal Society on the inheritance of disease of fruit trees and the propagation of debility by grafting. This paper was succeeded by accounts of experimental researches into vegetable fecundation, the ascent and descent of sap in plants, the phenomena of germination, the influence of light upon leaves, and a great variety of similar subjects. Knight was an original member of the Horticultural Society founded in 1804. In 1805 he was elected a fellow of the Royal Society and in the following year was awarded the Copley Medal. In 1811 he succeeded Sir Joseph Banks as president of the Horticultural Society, founded in 1804, and held office until his death. The Knightian Medal was founded in his honour. He was "a man of great patience and great perseverance, and seems to have had a charming personality, warm-hearted and generous, a little hasty at times, but of great kindness". His "Physiological and Horticultural Papers" were published in 1841, with his Life prefixed. In addition to numerous papers in the transactions of the Horticultural and Linnean Societies he was the author of "A Treatise on the Culture of the Apple and the Pear", "The Manufacture of Cider and Perry" (1797) and "Pomona Herefordiensis" (1811).

National Standards of Length and Weight

In his autobiographical notes for 1838, Airy wrote: "The National Standards of Length and Weight had been destroyed in the fire of the Houses of Parliament (Oct. 16, 1834). On May 11th I received a letter from Mr. Spring Rice, requesting me to act (as chairman) with a committee consisting of F. Baily, J. E. Drinkwater Bethune, Davies Gilbert, J. G. S. Lefevre, J. W. Lubbock, G. Peacock, and R. Sheepshanks, to report on the steps now to be taken. I accepted the charge, and the first meeting was held at the Observatory on May 22nd; all subsequent meetings in London, usually in the apartments of the Royal Astronomical Society, I acted both as chairman and as working secretary. Our enquiries went into a very wide field, and I had much correspondence."

This was the beginning of the long and laborious investigations and experiments which led to the construction of the new standards. Most of the work was done by Baily, who died in 1844, and Sheepshanks, who died in 1855, the day before the Royal Assent was given to "an act for legalising and preserving the last standards of weights and measures". This act provided that "The straight Line or Distance between the Centres of the two Gold Plugs in the Bronze Bar deposited in the Office of the Exchequer as aforesaid shall be the genuine standard of that Measure of Length called a Yard and the said straight Line or Distance between the Centres of the said Gold Plugs or Pins in the said Bronze Bar (the Bronze being at a temperature of Sixty-two Degrees by Fahrenheit's Thermometer) shall and be deemed to be the Imperial Standard Yard".

On June 18, 1857, Airy read to the Royal Society an "Account of the Construction of the New National Standard of Length, and of its Principal Copies."

The history and development of standards of measurement formed the subject of Sir R. T. Glazebrook's Guthrie Lecture to the Physical Society of London on May 15, 1931 (see NATURE, **128**, 17, July 4, 1931).

The London and Southampton Railway

Under the date May 12, 1838, the *Gentleman's Magazine* recorded, "The works upon The London and Southampton Railway having been so far completed as to permit its being opened to Woking-common, a distance of twenty-three miles from London, the first experimental trip was made, when the Directors, accompanied by their chief engineer Mr. Locke, by several noblemen and by many Members of Parliament, paid a flying visit to the admiring rustics who had congregated in thousands at Woking. The party assembled at the handsome and convenient terminus at Nine Elms, near Vauxhall Bridge. Rolling onwards at an equal but rapid rate Wandsworth and Wimbledon were soon passed; Merton was seen on the left; and in a few minutes Kingston with all its lovely scenery showed itself in the distance. . . . Byfleet and the long and beautiful range of hills which bound the neighbourhood of Leatherhead and Dorking" could be seen, "and a few minutes afterwards the station of Woking-common was gained. The whole distance was accomplished in 45 minutes."

University Events

Birmingham.—The Huxley Lecture is to be given by Prof. Ernest de Selincourt on May 19 at 5.30 p.m.; he will take as his subject "Literature and Science".

Cambridge.—The following have been appointed University demonstrators in anatomy: E. W. O. Adkins, of St. John's College; G. D. Channell and F. Wemyss Smith.

It is proposed to confer the degree of Doctor of Science, *honoris causa*, upon F. P. Rous, of the Rockefeller Institute for Medical Research in New York.

Oxford.—In Convocation on April 26 it was agreed that the honorary degree of D.Sc. should be conferred on July 16 on Dr. Harvey Cushing, emeritus professor of surgery at Harvard University.

St. Andrews.—The Court has appointed Dr. W. F. K. Wynne-Jones, of the University of Reading, to the chair of chemistry in University College, Dundee, which will become vacant on September 30 by the retirement of Prof. Alexander McKenzie. Mr. J. Norman Davidson has been appointed to the vacant lectureship in bio-chemistry in University College, Dundee.

Societies and Academies

Dublin

Royal Dublin Society, March 22, 1938.

Paul A. Murphy: A study of the seasonal development of the potato plant in relation to blight attack and spraying. The rate of growth of foliage and tubers was studied on potatoes on which *Phytophthora infestans* was perfectly controlled, commercially controlled, and uncontrolled. The first effect of spraying was generally to check the production of foliage and tubers, and reduce blossoming, but during the drought of 1933 the foliage was increased, as has been found under similar conditions in the United States.

H. H. Dixon: Subaqueous transpiration. This note deals with the criticism of Smith, Dustman, and Sheill, of a paper published by the author in 1898 on transpiration into a saturated atmosphere. The critics repeated the author's experiments with material from several species, always with negative results. They concluded, not realizing the precautions that had been taken, that the early results were due to water-deficit in the experimental material. In the present work, positive results were obtained with branches and leaves which had been kept twenty-four hours submerged and freely supplied with water. The material used by the critics was similarly treated for only one or two hours. Hence the objection of water-deficit cannot be raised. Probably some difference in technique, or in the physiological state of the material, was responsible for the discrepancy.

Paris

Academy of Sciences, March 7 (*C.R.*, 206, 705–792).

Léon Lecornu: Cutting a solid body.

Pierre Lejay and Chang Hung Chi: Measurements of gravity in the south of China. The measurements given were made with the Holweck-Lejay pendulum. In order to avoid the large temperature corrections necessary with this instrument, a field thermostat was devised capable of maintaining a constant temperature for several hours.

Wolfgang Dœblin: Study of the ensemble of powers of a law of probability.

Robert Fortet: The resolution of a system of equations of Schrodinger.

Henri Eyraud: Certain decompositions in imaginary chances.

Max Zorn: The lemma of Schwarz.

Ernest Vessiot: The equations $F(x,y,z,p,q,r,s,t)=0$ integrable by the method of Darboux.

Szolem Mandelbrojt: The applications of a theorem on the arguments of singularities.

Ayzyk Gorny: Functions indefinitely derivable on the whole of the real axis.

Georges Valiron: The directions of Borel of meromorph algebroid functions of infinite order.

Arnaud Denjoy: The singularities of an analytical function defined by an element.

Raymond Tremblot: The multiple spectroscopic stars 52 and 58 Perseus.

Théodore Kahan: Shock between a high-energy neutron and a proton treated by the method of approximation of Born.

Manuel Valadares and Francisco Mendes: Study of the $L\alpha$ satellites for the element 82 (Pb).

Guy Emschwiller: The photochemical oxidation of methylene iodide: the production of iodic anhydride. Methylene iodide with oxygen in a closed vessel exposed to ultra-violet light gives iodine, formaldehyde, formic acid, carbon monoxide and iodine pentoxide, the last in appreciable quantity.

René Audubert: The ultra-violet emission spectrum and slow thermal dissociation of sodium hydrazoate.

Frédéric Joliot and Ignace Zlotowski: The energy of the groups of protons emitted during the transmutation of boron by the α-rays.

Mlle. Marie Théodoresco: The Raman spectrum of some molybdates in aqueous solution.

Victor Auger and Mlle. Nina Ivanoff: Ammonium magnesium arsenate and alkaline earth arsenates.

Charles Dufraisse and Jean Houpillart: Syntheses in the naphthacene series: naphthacene-diaquinone.

Bernard Gèze: The genesis of the Quercy phosphorites.

Otto Munerati: The use of rhizogene compounds for favouring the formation of roots and of flower bearing stems on the collars of the beetroot.

Robert Douin: The photo-geotropic sensibility of the sporogone of the Hepaticæ.

André Mirimanoff: Vitamin C and chlorophyll. Determinations of ascorbic acid in various organs of plants by Meunier's method leads to the conclusion that the antiscorbutic value of a plant does not depend on the presence of chlorophyll.

René Souèges: The embryogeny of the Portulaceæ. The development of the embryo in *Portulaca oleracea*.

René Moricard, Mlle. Simone Gothié and Basile Tsatsaris: The realization of a culture medium deprived of animal matter and allowing the maturation of the ovules of mammals.

Jean Jacques Bounhiol: The possible role of the frontal ganglion in the metamorphosis of *Bombyx mori*.

Mlle. Yvette Neefs: Remarks on the sexual cycle of the sea-urchin, *Strongylocentrotus lividus*, in the Roscoff region.

Eugène Aubel, Wastroslaw S. Reich and F. Michel Lang: The state of the glycogen in the liver.

Maurice Lecamp: The regeneration of the limbs in *Carausius morosus*.

Edgar Lederer and Franz H. Rathmann: The vitamins A_1 and A_2.

Robert Paulais: The colorimetric estimation of iron. Application to the analysis of biological substances.

Henri Bierry, Marcel Andrac and Bernard Gouzon: The globulines and reagines of syphilitic sera.

Maurice Doladilhe: The antibody property of hæmolysin is exercised by a substance isolable from hæmolytic serum.

Cracow

Polish Academy of Science and Letters, February 7.

T. Banachiewicz: Rotations in space of four dimensions and the two aspects of the equations of spherical polygonometry.

J. Pniewski : Studies on the diffusion of light in the edges of the Rayleigh line in carbon disulphide. The distribution of the intensities of this line observed in carbon disulphide cannot be explained by the Raman theory of diffusion due to the rotation of the molecules

Mlle. B. Twarowska : The absorption spectra of biacene and fluorocyclene.

D. Doborzynski : Measurements of the dielectric constant of solids by means of ponderomotive forces.

F. Kepinski : The movement of the periodic comet of Kopff (1906 c).

W. Opalski : Microphotometric measurements of SU Draconis in 1935–1936 and their comparison with preceding measurements.

M. Centnerszwer and Mlle. H. Ladzinska : The lowering of the boiling point of a ternary system by non-volatile substances. (2) Mode of behaviour of cobalt chloride and sodium nitrate in water.

M. Centnerszwer and Mlle. K. Zolatkowska : The lowering of the boiling point of a ternary system by non-volatile substances. (3) Aqueous solutions of calcium nitrate.

M. Centnerszwer : The lowering of the boiling point of a ternary system by non-volatile substances. (4) Certain properties of isozeonic solutions.

St. Kreutz : The amphibolites of the Tatra.

F. Weiler : Mode of behaviour of roots under the action of growth substances contained in the germs of oats and maize.

Geneva

Society of Physics and Natural History, February 3.

Paul Rossier : Accuracy of measurements with the Thomson bridge. The influence of a difference between the resistances which ought to be equal in the bridge is reduced to a minimum if the connection resistances are made as small as possible, in this way resembling the Wheatstone's bridge.

Paul Rossier : The determination of the coefficients of leak of electrical machines. The addition of supplementary coils, the use of known resistances one of which can be altered, and of an ordinary or differential galvanometer allows a simple determination of this coefficient.

Emile Guyenot and Kitty Ponse : Antihormonal immunization and specificity. The immunization obtained by a prolonged treatment with prepituitary extracts of the ox, protects the animals against the action of the thyroetrope and crinogen hormones arising from the ox or sheep, animals belonging to the same group, whilst it is without action towards the same hormones of the pig, horse and man. Hence the reaction is specific. Moreover, the immunization appears to be set up not towards common albumens, but with respect to the protein molecules which constitute the hormones themselves.

Emile Cherbuliez and Anna Herzenstein : The differential estimation of the reducing acids of sulphur. The differential estimation of various reducing sulphur acids in sulphurous waters may be carried out, even at very low concentrations, in the following manner. (1) Determination of the total reducing power by iodine. (2) Determination of hydrogen sulphide or of the sulphides by precipitation with cadmium carbonate or acetate and titration of the precipitated sulphide by iodine. (3) Determination of the thiosulphuric acid or of its salts by iodine, after eliminating sulphuretted hydrogen and an unknown reducing agent by means of potassium iodate in neutral solution. This last reaction is new. The authors have applied the method to Pistany (Czechoslovakia) waters which contain the following reducing sulphur acids : hydrogen sulphide, thiosulphuric acid and an unknown reducing agent which is perhaps hydrosulphurous acid ($H_2S_2O_4$.)

Fernand Chodat and Paul Brunschwig : New researches on cresol blue (tyrosinase, paracresol, amino acids). The authors have measured the quantity of oxygen fixed in the course of the first phase of the synthesis of cresol blue, and have arrived at the following results. The amino acid has nothing to do with the quantity of oxygen fixed, the latter depending only on the concentration of the oxidizable phenols. Each molecule of paracresol fixes a little less than three atoms of oxygen. The oxidation of the phenol, catalysed by the tyrosinase, is much more rapid in the presence of the amino acid (glycocol).

Moscow

Academy of Sciences (*C.R.*, 18, No. 1, 1938).

Loo-Keng Hua : Some results in the additive theory of numbers.

I. I. Privalov : (1) Applications of the idea of harmonic measure to certain problems of the theory of functions. (2) Limit problems of the theory of harmonic and subharmonic functions in the space.

S. A. Tchounikhin : Groups with predetermined subgroups.

I. A. Čarnyi : Theory of unidimensional non-stationary movement of fluid in tubes.

L. Sedov : Hydrodynamic theory of grid.

P. Kapitza : Viscosity of liquid helium below the λ-point.

S. N. Rshevkin : Possibility of obtaining high coefficients of sound absorption by using systems of resonators.

A. A. Geršun : Photometric invariant.

P. A. Bobrov, L. I. Kolotova and V. A. Zamyatina : Investigation of decomposition products of lignin.

D. I. Rjabtschikow : Thiosulphate compounds of the bivalent platinum. (1).

D. J. Vakulin : The problem of the responsiveness of *Lallemantia iberica* F × M to vernalization.

N. S. Petinov and G. A. Zak : The problem of the hardening of plants by soil dryness under conditions of irrigation. (1) The effect of hardening on growth and formative processes.

N. S. Petinov : The problem of the hardening of plants by soil dryness under conditions of irrigation. (2). The effect of hardening on photosynthesis and yield.

A. A. Richter and O. K. Elpidina : The practice of aerial fertilization with carbon dioxide.

D. A. Komissarov : Application of growth substances to increase the rooting capacity in cuttings of woody plants and shrubs.

N. S. Petinov : The effect of continuous and discontinuous water supply on the photosynthetic process and the yield of summer wheat.

Forthcoming Events

[Meeting marked with an asterisk is open to the public.]

Monday, May 9

Royal Geographical Society, at 8.30.—Capt H. C. Smith: "On the Frontier of British Guiana and Brazil".

Tuesday, May 10

Gresham College, Basinghall Street, London, E.C.2, at 6.—A. R. Hinks, F.R.S.: "Astronomy for Surveyors and Navigators". (Gresham Lectures on Astronomy.) (Succeeding lectures on May 11, 12 and 13.)*

Institution of Civil Engineers, at 6.—Annual General Meeting.

Wednesday, May 11

Society for the Study of Alchemy and Early Chemistry (at the British Academy, Burlington Gardens, W.1), at 8.—Prof. J. Read, F.R.S.: "Alchemy under James IV of Scotland".

Thursday, May 12

Royal Society, at 4.30.—Discussion on Plastic Flow in Metals, to be opened by Prof. W. L. Bragg, F.R.S.

Institution of Electrical Engineers, at 6.—Annual General Meeting.

Dr. A. P. M. Fleming: "The Evolution of Electrical Power" (Faraday Lecture).

Friday, May 13

Royal Astronomical Association, at 5.—Prof. Charles Fabry. "Interstellar Space" (George Darwin Lecture).

Royal Institution, at 9.—J. M. Wordie: "An Expedition to North-West Greenland and the Canadian Arctic".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant Lecturer in Physics in the University of Sheffield—The Registrar (May 9).

Scientific Officer (Explosives) and Junior Scientific Officer (Metallurgy) in the Research Department, Woolwich, S.E 18—The Chief Superintendent (May 10)

Lecturer in Mechanical Engineering in the Dudley and Staffordshire Technical College—The Principal (May 12).

Technical Officer and Assistant (II) for Radio Research, War Department—The Secretary, Royal Engineer and Signals Board, Regent's Park Barracks, Albany Street, N.W.1 (May 18).

Principal Technical Officer (Ref. No. 32 B) and Technical Officers (Ref. 33 B) in the Aerodynamics Department, Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (May 13 and May 14 respectively).

Agricultural Bacteriologist in the Punjab Agricultural Service (Class I)—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2, by postcard (May 18).

Assistant Lecturer in Mathematics, with qualifications in applied mathematics, in the University of Manchester—The Registrar (May 14).

Assistant (grade II) for aircraft instrument work at the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent, quoting Ref. No. 37 B (May 14)

A Technical Officer (Ref. 20 B), an Assistant (grade I; Ref. 21 B), an Assistant (grade II; Ref. 22 B), an Assistant (grade III; Ref. 23 B) for electrical equipment work at the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (May 14).

Lecturer in Bacteriology in the University of Birmingham—The Secretary (May 14).

Assistant Field Supervisor at the Norfolk Agricultural Station—The Director (May 14)

Assistant Lecturer in Chemistry in the Technical College, Bradford—Director of Education, Town Hall, Bradford (May 14).

Assistant Lecturer in Chemistry in the Technical College, Bradford—The Principal (May 14)

Lecturer in Psychology in the Victoria University College, Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, 88a, Gower Street, London, W.C.1.

Examiner in the Petroleum Laboratory and Women Examiners in the Non-Metallic Section of the A.I.D. Test House, Kidbrooke, London, S E.3—The Secretary, Air Ministry, Kingsway, London, W C.2 (quote I G 10 and I.G 11 respectively).

Assistants (grade III, male) in the Meteorological Office, Air Ministry—The Secretary (S.2A), Air Ministry, Adastral House, Kingsway, W.C.2.

Assistant Civil Engineers in the Civil Engineer-in-Chief's Department, Admiralty—Civil Engineer-in-Chief, marked "A C.E. April".

Assistant Civil Engineers in the Air Ministry—The Secretary (W 9), enclosing addressed envelope.

Assistant in the Intelligence Section of the Mineral Resources Department, Imperial Institute—The Establishment Officer

Junior Scientific Officer at the Low Temperature Research Station, Cambridge—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, London, S.W 1 (postcard quoting J.38/4).

Lecturer in the Mathematics Department of Heriot-Watt College, Edinburgh—The Principal

Physical Fitness at Universities

THOSE Englishmen—unfortunately still very few—who are acquainted with the universities of Canada and the United States, have long had cause for astonishment, indeed for shame, at the way in which the universities of Great Britain have lagged behind those of America in their care for the health and fitness of their students. In those countries at any rate, it cannot be suggested that the desire to produce a healthy population is a sign of latent militarism or of any peculiar brand of politics. To an American or Canadian student—or professor—visiting Great Britain, it seems incredible that in most of our universities there is no medical examination whatever, either at entry or later on, no organized system (voluntary or compulsory) of physical exercise, little provision (except in a few privileged places) for healthy recreation 'in the spare half-hour', no arrangement to provide medical or surgical advice or treatment when required.

A wider knowledge of our deficiencies in this respect, and perhaps a stimulus to make them good, is given by a very timely pamphlet, "Student Health", recently issued by the National Union of Students.* In this pamphlet the need of student health services and of greater facilities for healthy exercise and recreation is discussed, the services and facilities existing in the United States, in Canada, in Germany and in Sweden are described, an account of what is already being done, or is contemplated, in the universities of Great Britain is set out, and a 'minimum policy' for the future is proposed.

The causes of this neglect are various and to some degree, at least, a matter for speculation: the medieval view, based upon a false antithesis of mind and body, that the universities exist solely for the training of the intellect; a superstitious horror of anything which might savour of organization, discipline or compulsion in personal affairs; a belief in the magic of *laissez-faire*; the dominant position in public life of Oxford and Cambridge, where the colleges exert a parental influence, where most of the students are not so poor, and where games and recreations are much easier to get; indifference; and a fear that students themselves might not co-operate. The last cause at least is removed by the publication of this pamphlet on behalf of the students themselves. It is peculiarly timely because, unknown to its writers, a new movement was already under way and that movement will be given greater confidence and strength by the knowledge that the National Union of Students is openly and emphatically sympathetic. The committee of the Union which discussed the matter "was struck with the fantastic lack of attention there had been in this country to scientific methods of physical education". "It became more and more impressed with the importance of preventive as well as curative methods". The systems in other countries, it found, "indicate a very general acceptance by the universities of a great measure of responsibility for the physical as well as the intellectual well-being of their students, a responsibility which is still to a large extent shirked by the universities of Great Britain".

In the autumn of 1937, the National Fitness Councils for England and Wales and for Scotland invited the University Grants Committee to advise on the distribution of a capital sum of £230,000 to aid the universities of Great Britain in providing urgently needed facilities for healthy recreation and for physical exercise. The sum itself is small—

---

* Student Health: the Report of an Enquiry into University Health Services by the National Union of Students. Pp. 104. (London: National Union of Students, 1938.)

only about one tenth of the annual Treasury grant, for all purposes, to the universities—and it can do no more (it was not intended to do more) than catalyse the interest of the universities themselves and perhaps of their potential benefactors. That, however, it is beginning to do, and although the £230,000 itself cannot be spent otherwise than on facilities for healthy recreation—on gymnasia, swimming baths, squash courts and the like—it has set the universities thinking and planning, and ultimately very much more may result. In most of them—indeed if not all—voluntary medical examinations are to be instituted, lectures will doubtless be given on matters relating to health, the status of members of the staff dealing with physical training is to be raised, the co-operation of scientific and medical departments is to be sought, committees are to be formed to consider the place of student health as a proper function of a university; and probably, under the guidance of the Medical Research Council, in certain special centres, a scientific examination of the problem is to be instituted. An attempt is to be made, in fact, to give to the subject of bodily and mental health and fitness its proper university status. Those, however, who take a longer view will realize that it is not merely 'student health' as such which is to be aimed at, but—through the universities—the intelligent and conscious application of a new biological outlook on human beings, an outlook intended ultimately to affect the entire community

Health is a positive thing, namely, living up to the best powers of the individual. It is not merely absence of obvious diagnosable disease. As a matter of fact, however, even among students, disease is common enough. A professor in a medical school writes:

"Recently there have come within my notice four students with mild or severe mental trouble, three cases of early tuberculosis, and a host of minor ailments, such as trouble with hearing, vision and teeth, tonsils, colds, influenza, muscular pains, skin diseases, lassitude, anæmia, and not so very infrequently fears about health."

What is true of medical students is just as true—though not perhaps so easily realized—of others. To recognize disease, or minor ailments, or chronic under-nutrition, or mental trouble, or anything lowering the level of happiness, fitness and usefulness in university students, and to provide means of improvement, are important enough. Even more important, however, in the long run, is to send out steadily into the community a stream of intelligent and keen young people who have learned, even in a minor way, what a health service can do for them and their friends, and how necessary it is to the happiness and well-being of the people.

Medicine at present consists too largely of the diagnosis and treatment of obvious disease, often when it is too late for complete health ever to be restored. Hospitals are crowded and only urgent cases can be considered. Human biology must take a much wider view than this of its duties and opportunities. Adequate nutrition, in quantity and quality, exercise suited to the needs and powers of the individual, healthy recreation, a sane outlook on bodily functions—not disregarding sex and reproduction—guidance and help in mental and emotional difficulty, the profitable use of holidays and leisure, all these require an educated public opinion. How better may that educated opinion be built up than by giving to those who pass through the universities some personal appreciation and understanding of the part which an adequate health service, taking account of all such factors and employing all the resources of science, can play in promoting the well-being of those whom it reaches?

Protection of Ancient Monuments in Britain*

THE recently issued list of monuments in England, Wales and Scotland now protected under the Ancient Monuments Acts contains the names of more than five thousand monuments. These are of all kinds from prehistoric camps, stone circles, and barrows to the remains of abbeys, castles, bridges and even relatively modern buildings. Three hundred and twenty-five monuments were added to the list in 1937. Especially noteworthy among the additions are Bewcastle Roman fort, St. Alban's Gatehouse, with its archway and turrets, Reigate old town hall, which it had been proposed to demolish, the remains of the palace of Archbishop Roger at York, dating from the twelfth century, and the remains of the monastic settlement on Faroe Island.

---

* Ancient Monuments of Great Britain List of Monuments to December 31, 1937, prepared by the Commissioners of Works. Pp. 101. (London. H.M Stationery Office, 1938.) 1s 6d. net.

Although the list is known not to be exhaustive, as is pointed out by Sir Patrick Duff in his introductory note, it serves to indicate the wealth of Great Britain in remains of historic and æsthetic interest, as well as the multifarious activities of the Ancient Monuments Branch of the Office of Works. Between 1921 and 1931 the Commissioners published lists which indicated from time to time the monuments to which State protection had been granted under the Act of 1913; but since 1931, when the new Act was passed, the list, which it is incumbent on the Commissioners to publish under the law, has been made more comprehensive by the inclusion of those monuments appearing in previous lists, as well as certain classes of monuments for which the Commissioners are responsible in various ways by deed of gift, guardianship, or purchase, or as Crown property, or as situated on Crown property, though not under custody. There also appear the buildings of historic or architectural interest, some wholly or partially in occupation, for the maintenance of which the Office of Works is responsible. Among those in this last category are the Banqueting Hall, Whitehall, the Jewel Tower, Westminster, Holyroodhouse, Edinburgh, Glasgow Cathedral and Dunblane Cathedral.

The interest of the list to the general public, and even its value to the expert, might be considerably enhanced by some such additions as a brief statistical statement in the nature of a progress report, an indication of the latest inclusions, and the date of protection of each monument. Although the introductory note records recognition by the Commissioners of the assistance of local archæologists in compiling the lists, archæologists on their side would acknowledge that the organization and personnel of the Ancient Monuments branch of the Office of Works, as at present constituted, provide a combination of scientific knowledge and practical training and experience best calculated to secure the co-operation of Government department and public, represented by the local expert, which it is the aim of successful administration in a democratic community to secure.

The departmental inertia in matters affecting our antiquities, which caused General Pitt-Rivers to refuse for many years to draw his salary as inspector of ancient monuments, has long been a thing of the past; and Sir Frederic Kenyon in his presidential address to the Society of Antiquaries on April 28 was fully justified in referring to the work of the Commissioners through the ancient monuments inspectorate as the most striking advance in the official recognition of archæology in our time. When, however, Sir Patrick Duff says that "the present enlarged list cannot be regarded as covering in a systematic way the whole of the more important Ancient Monuments of Great Britain", and Sir Charles Peers can tell the Oxford Branch of the Council for the Preservation of Rural England, at the meeting at Oxford on April 30, that the work already done in the protection of ancient monuments is no more than a beginning, it is evident that no means should be neglected to enlist the interest of the public, if the State, as many would like to see, is to take a greater and more responsible share in the systematic advancement of archæological knowledge. The more widely it is known how much is already accomplished by the Office of Works in the course of the year, the more readily will it be possible to win public support for an extension of its activities.

Ideals and Conflicts of Civilization

Ends and Means:

an Enquiry into the Nature of Ideals and into the Methods employed for their Realization. By Aldous Huxley. Pp. v + 336. (London: Chatto and Windus, 1938.) 8*s*. 6*d*. net.

SIX years ago Mr. Huxley presented to the world the picture of a "Brave New World". The days of that scientific Utopia, so cleverly constructed with satire and malice out of Mr. Huxley's rich imagination, are gone. The brave new world is changed to the Utopia of an evangelist, a Utopia seen through the haze of an infinitely troubled world. "Ends and Means" deals with the critical state of present world conditions and with the ideal individual. It considers the problems of domestic and international politics, of education, of religion and ethics, and in it Mr. Huxley tries to suggest a way out of the conflicts which now threaten the destruction of civilization.

Mr. Huxley has applied himself to his task with a faith that cannot fail to command respect, and with a certainty which belongs far more to the mystical world of religious reformers than to the world of reality in which the book was written. The gloomy picture which he paints of the state of the world is also so familiar that at first one fails to realize that it is charged with a brilliant analysis of the conditions that have led to it, and with an equally brilliant statement of the only possible outcome if existing social trends remain as they are. But Mr. Huxley differs from most other social reformers in what he thinks necessary to transform our present social environment into a better one. He does not share the common belief that the way to alter the structure of society is through large-scale political and economic reforms. On the contrary, he holds that transformation brought about by such means would not be accompanied by that necessary change of heart, by that free renunciation of personal ambitions which in his opinion alone can transform human society into an association of peoples in which the first consideration is the common good. National planning he finds inconsistent with international peace, and he argues convincingly that the defence of democracy against fascism inevitably entails the transformation of democracy into fascism. After considering many possible principles of social change, he concludes that the only certain political road to social security is non-violence and decentralization. To achieve these ends he asks that all people should become "non-attached"—non-attached to power, to possessions, to bodily sensations, to fame, non-attached even to science, art and philanthropy. It is plain that to enter Mr. Huxley's kingdom of man, man must completely stop being the mammal we know him to be. Unfortunately, the educational policies, and the mental and physical exercises which he suggests will bring about this transformation, are scarcely practical enough for our immediate needs.

In the few months that have passed since Mr. Huxley's book appeared, society has become even more insecure than it was when the book was written. Mr. Huxley's views have correspondingly receded further from any realm of practical politics. Retreat to mysticism is a poor prescription for the millions who already, through the turn of political fortune, have to face violent death. To suggest that ruthless dictatorships can be opposed by masses determined not to use violence seems equally unreal—for in the absence of opposition there seems no reason why ruthlessness should not continue for ever. Mr. Huxley's argument almost leads to the conclusion which he is anxious to avoid, to the view that violent dictatorships can only be opposed by violence. But irrespective of any such considerations, one has to remember that most of those who make up the world's population are completely unaware of their "attachments", and especially of those particular attachments the interplay of which, in the form of national politics, are most responsible for the present critical condition of society. Politics, it may be true, becomes more and more a game whose counters are *a priori* concepts that are devoid of meaning, counters whose moves completely obscure the simple wishes of simple people. It is, however, no use supposing that one set of *a priori* concepts are any more valid than any other. To use "spiritual exercises" to get "spiritual insight" into "ultimate reality", to form "a mystical union of the soul with the integrating principle of all being", concepts which Mr. Huxley advances, means no more to the vast majority, perhaps even less, than to use "national honour" to defend the "vital interests" of "society", concepts which Mr. Huxley may rightly regard as empty of real meaning and as propaganda to further the exploitation of the many for the benefit of the few. One cannot help wishing that Mr. Huxley, in discussing the vital issues which make up his book, had himself abided by his desire for terms of "concrete contemporary reality".

The most vital of all these issues is the fact that now, almost more than at any other time in human history, there is a premium on human aggressive tendencies, and the most vital of all the problems considered by Mr. Huxley is that of finding means for restraining these tendencies. Mr. Huxley admits that reforms can transfer the undesirable tendencies of individuals from one channel to another channel, but because transference does not abolish what he regards as a fundamental evil, he detracts somewhat from the value of reforms which bring it about. So fundamental an evil as aggressiveness, which observations suggest is a biological heritage, can scarcely be dissipated at its source in the way Mr. Huxley suggests, and it is plain that our only immediate hope of securing the future is to divert, through scientific planning, expressions of dominance from more undesirable to less undesirable fields of social activity. Science cannot be treated, as Mr. Huxley often treats it, as though it were some human epiphenomenon. "Technological progress," he writes, "has reduced the number of physical contacts, impoverished the spiritual relations between members of a community." Whatever these particular relations may be, it is even more true that science has also immeasurably enriched other and more immediate relations between human beings. Technological progress may have provided us "with more efficient means of going backwards". It has no less provided us with more efficient means of progressing. If the civilization of to-day fails to take advantage of these possibilities, it will not be because of the introduction of scientific method into social affairs—for it is certain that success will be achieved only when that which is rational becomes enthroned. Mr. Huxley's present mysticism will not clear the darkness which at present prevents the application of reason in social affairs.

In spite of the shortcomings of the plans it advocates, Mr. Huxley's book is a magnificent achievement, and it is impossible not to be deeply impressed by the wide sweep of his imagination and knowledge. His method of saving the world may not be effective. He has, however, more than helped to outline the problems by which we are faced, and in doing so he has written a book which, in carving its own territory, has cut across all accepted lines of politics and belief.

Climatology of the British Isles

The Climate of the British Isles: being an Introductory Study of the Official Records, for Students and General Readers. By E. G. Bilham. Pp. xix + 347. (London: Macmillan and Co., Ltd., 1938.) 21*s*. net.

In this book Mr. Bilham, superintendent of the British Climatology Division of the Meteorological Office, sets out to compile a reasonably complete summary of the main climatic features of the British Isles within the compass of a book of reasonable size. The book runs to 339 pages, and achieves in a marked degree the avowed intention of the author, and so meets a very long-felt want of meteorologists and geographers. It contains a wealth of information of a statistical character concerning the climatic elements of importance, all discussed and compared in a clear and interesting manner. Much of the information contained in the book has not hitherto been available in printed form, while still more was only available in the rather arid form of such publications as the "Book of Normals".

The book begins with a discussion of the nature of the observations to be treated. Here we find mention of a point all too frequently ignored, that the meteorologist's fog, meaning visibility of less than 1,000 yards, is not of necessity fog to the ordinary man. The motorist, for example, thinks of a fog as a condition which seriously interferes with driving, which corresponds with visibility less than 100 yards.

Mr. Bilham describes the evaluation of the standard deviation and probable error of rainfall statistics, pointing out that the use of these parameters involves the assumption that the data fulfil the normal law of error, which, he says, is not likely to be strictly true. This is obviously so of rainfall, since rainfall is of necessity a positive quantity, while amounts of double the mean are by no means rare. It would therefore have been of interest to know how wide of the truth the assumption of a normal distribution really is. The author has treated the type of distribution of pressure, in accordance with Gold's classification, as a climatic element, the frequency distribution of which at different times of the year is given. This is a new departure in a text-book of climatology, and a welcome one.

Without going into the details of the contents of the book, we may say that the data for wind, rainfall, evaporation and run-off, temperature, sunshine and cloud, humidity, ground frosts, snow, hail, thunderstorms, and visibility, are given as fully as can be expected in any text-book. The mass of data concentrated into these pages bears testimony to the skill of the author, as well as to his mastery of the subject. Although the book is perhaps to be judged as a collection and discussion of the facts of observation rather than as an introduction to general climatology, it is readable and interesting. It will prove not only useful as a text-book for the meteorologist and geographer, but will also be extremely useful to the research worker who desires to know at what point to take up the climatology of any special region.

So much being given, it may appear ungrateful to ask for more. In discussing wind data, Mr. Bilham gives on p. 59 a table of the frequencies of winds of different velocities for January, July and the whole year. The reader who is likely to make real use of the data for January and July is also likely to want similar data for the other months of the year, and it would be possible to suggest a number of uses for such tables for each month of the year, for a number of places distributed over the British Isles.

The occasions of very high wind, of very heavy rain, of abnormally high or low temperature, are shown in convenient tables, and these tables should enable the weather correspondents of the daily newspapers to check up their frequent comparisons with record occasions. In passing, the author stays to scoff at the dew-pond, pointing out that the main factor in the maintenance of the high level in the pond is the fact that it collects rain from a much greater area than the surface area of the water exposed to evaporation. This fact is probably enough to account for the observed phenomena, but it might also be pointed out that any comparison of the dew-pond with the actual formation of dew on grass should be restricted to the dew which *falls*, since over the pond there is no phenomenon corresponding to the dew which is formed by condensation from the air rising from the soil.

The final chapter of the book is devoted to the special types of climate, such as those of coastal areas, inland areas, valleys and towns; and an appendix gives for thirty-nine stations a synopsis of monthly data of cloud, visibility, temperature, rainfall and sunshine. This table, giving as it does the most recent determinations of the normal values of these factors, is one of the most valuable features of the book.

Mr. Bilham's book is one of the most useful additions to the meteorologist's library which has appeared in recent years. Although it is to be judged as a summary of the climatological data for a restricted area rather than as a discussion of the physical principles of climatology, the author's keen sense of the relative importance of the various factors of climate has led to the interpolation of remarks which are of the utmost importance to the clear understanding of the data. The attention directed to the importance of gust-level as compared with mean wind in determining the damage caused by wind, might be cited as an example of such happy interpolations. For a first edition the book is remarkably complete, particularly in view of the fact that it is the first serious attempt to produce a climatology of the British Isles.

D. BRUNT.

Popular Science

(1) The Advancing Front of Science

By George W. Gray. Pp. xiii + 364. (New York and London: McGraw-Hill Book Co., Inc., 1937). 12*s*. 6*d*.

(2) Frontiers of Science

By Carl Trueblood Chase. Pp. xv + 340 + 19 plates. (London: English Universities Press, Ltd., 1937.) 12*s*. 6*d*. net.

(3) The Universe Surveyed: Physics, Chemistry, Astronomy, Geology

By Harold Richards. Pp. xvii + 722. (London: Kegan Paul and Co., Ltd., 1938.) 12*s*. 6*d*. net.

TO those who would like to see not only scientific knowledge but also scientific action play its part in developing civilization, popular science literature is a painful subject. So much of it is either inaccurate or unscientific. Admittedly technical writing on any technical subject is easier than accurate non-technical writing on the same subject.

The bulk of the science literature for the general reader happens to be prepared by two quite different classes of writer, the journalist and a few very distinguished men of science. The journalist has a very difficult task in that he may be unable to read the original research papers and economic pressure may prevent his taking too much time in understanding their subject-matter. The distinction between observable facts and interpretations of facts is likely to be completely lost. Moreover, he is apt to seek only those parts of scientific research which have news value.

On the other hand, the expert scientific workers, with one or two notable exceptions, have so far chosen to present to the general reader a very little that is science with much that is philosophy or mysticism. Even a little theology may be introduced. Both classes of writer use freely, without definition, such highly technical philosophical terms as *truth*, *existence*, *reality*, and *values*, where equally technical but more easily definable scientific terms are carefully avoided. It is not, therefore, surprising that outside the research laboratory there is little or no idea of what is typically scientific action and what is not.

(1). The first of these three volumes, "The Advancing Front of Science", by G. W. Gray, is specially welcome. Although written by a journalist, it is outstanding for its clear and generally accurate account of recent researches. Attention is directed to current work in representative fields of science, the earlier parts of the researches having been dealt with in the author's preceding book. From the nature of the writing, and from the three-page list of acknowledgments, it is clear that the information has been sought in the laboratories in America where the researches were carried out. Mr. Gray has been fortunate, not only in his opportunities of consulting many of the leading workers in America but also in his powers of grasping and conveying to the reader the results of his contacts. The choice of topics ranges from cosmic and atomic physics to recent developments in acoustics, chemistry and biology.

Sometimes the personal element is introduced, as in the chapter dealing with Langmuir's work on thin films, where biographical details are also given. There are occasional slips. For example, when referring to man's inability to survive for long a small change in his body temperature, the phrase "a 1 per cent change" in temperature is used

(p. 20). Then again, on p. 179, "These two separated hydrogen atoms, with their natural affinities now loose and unsatisfied, were eager for any kind of union". It is surely difficult for any scientific investigator to tell whether or no atoms are 'eager'. There is also the customary carelessness in using technical philosophical terms. In spite of these slight blemishes, the volume can be very strongly recommended.

(2) The scope of the second volume, "Frontiers of Science" by C. T. Chase, is very similar. Yet in spite of its excellent illustrations, the account is much less vivid. To the reviewer it savours more of the atmosphere of the science library than of the research laboratory itself. If popular science writers insist on using animistic explanations in physics, would it not help to push the method to its logical conclusion ? Mr. Gray's atoms can be 'eager' ; Mr. Chase's electrons can 'make decisions'. "What happens when an electron decides to break away from an atomic nucleus ?" (p. 249).

(3) Instead of bringing animistic explanations up to date by giving atoms and electrons instincts or Œdipus complexes and the like, Prof. Richards in "The Universe Surveyed" seems, on p. 5, to go back to the early appeal to what is 'natural', giving, incidentally, vectorial qualities to hydrostatic pressure. "It is natural for water to run down hill. This is a consequence of the tendency of water to flow in the direction of the greater pressure." The writing is so 'bright' that it is sometimes difficult to tell which passages are offered as explanations and which as rhetorical devices planned to ridicule.

'Why' questions are frequently asked. "Why do we fall when the foot-bridge breaks under us ? . . . the answer itself, when finally discovered, was found to link us with the stars" (p. 17). Such a passage is apt to give the impression that the scientific investigator can answer 'Why' questions and moreover that the finality of a scientific explanation can be determined. The most noteworthy features of the book are its many excellent illustrations and the inclusion of a section on geology. The title is much too comprehensive in that the universe surveyed is chiefly the non-biological part of the universe. Even vitamins and hormones are treated chiefly from the chemical point of view and psychology is barely mentioned.

The outstanding excellence of Mr. Gray's book overshadows all except the illustrations of the other two volumes. W. H. GEORGE.

Human Ecology

Life as a Whole
By Dr. J. W. Bews. Pp. ix + 347. (London, New York and Toronto : Longmans, Green and Co., Ltd., 1937.) 15s net.

PROF. BEWS' book is very difficult to review and, but for the evidence of the accomplished fact, might have been thought impossible to write. It is intended to supplement his previous work "Human Ecology", which was a study of man in relation to his environment—material, social and cultural. The present work is an attempt at a more complete synthesis. It is written explicitly from the point of view of General Smuts's theory of 'Holism'. The development of mankind is considered as the construction or creation of new 'wholes', whether these are mechanical inventions, social institutions, scientific and philosophical theories, or works of art. The author's general conclusion is that all human constructions are imperfect and may have to be pulled down and reconstructed. The pulling down may necessitate temporary reversion to more primitive and simpler conditions.

Perhaps the least satisfactory parts of the book are the chapters dealing respectively with social life and institutions, history and philosophy, art, architecture, music, literature. Twenty pages or so are devoted to describing the endeavours of the whole human race in each of these directions. The reader who knows about the subject is likely to be exasperated and the reader who does not bewildered. At almost any point he will be likely to ask : Why is this put in and why is that left out ?

One does not know whether to praise Prof. Bews for his courage or condemn him for his rashness. Yet it is hard to see what else he could do. If the chapters had been expanded to two hundred pages or contracted to two, it would probably have been worse. That is one of the reasons why a book of this kind seems impossible to write.

The earlier chapters, the subject-matter of which may be roughly indicated by the term social psychology, are more satisfactory. Occasionally Prof. Bews may have chosen to follow opinions of doubtful reliability, but as he quotes his authorities this cannot do much harm. In any event we should be grateful to one who brings to his survey of mankind moderation, reason and sanity, at a time when these virtues are being extinguished in many quarters. A. D. R.

Sex and Personality:

Studies in Masculinity and Femininity. By Lewis M. Terman and Catherine Cox Miles, assisted by Jack W. Dunlap, Harold K. Edgerton, E. Lowell Kelly, Albert D. Kurtz, E. Alice McAnulty, Quinn McNemar, Maud A. Merrill, Floyd L. Ruch, Horace G. Wyatt. (McGraw-Hill Publications in Psychology.) Pp. xii+600. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 25*s*.

THE purpose of this work, which the authors regard as a pioneer attempt, is the accomplishment in the field of masculinity and femininity of something similar to Binet's early achievement in the field of intelligence, inasmuch as they have endeavoured to apply psychometric methods in the form of a test to the study of sex temperaments. The test was originally devised by the senior author, Lewis M. Terman, in 1922 in the investigation of intellectually superior children, and has since been applied in the examination of a great variety of groups, including college students, office workers, athletes, delinquents, homosexuals and prostitutes, the ages ranging from early adolescence to extreme old age.

The test is made up in two equivalent forms, *A* and *B*, and is composed of 910 items of the *questionnaire* variety, 456 in form *A* and 454 in form *B*. Although the test does not differ radically from previous methods in the study of sex differences, it represents a more systematic attempt to sample sex differences in a large variety of circumstances. The authors maintain that the types of investigation in which the test should be helpful include the relationship of masculinity and femininity of temperaments to body build, metabolic rate and other physiological factors, excess or deficiency of gonadal and other hormone stimulation, and homosexual behaviour, and to such environmental influences as parent-child attachments, number and sex of siblings, sex of teachers, type of education, marital compatibility and choice of friends or of occupations.

Philip's Biology Wall Charts

Designed and Drawn by the Rev. R. A. Ellis and A. E. Ellis. A. 1: Flower Colour. A. 2: Plumage Colour. A. 3: Shell Colour. A. 4: Comb Characters. B. 5: Skull of Dog. B. 6: Skull of Dog. B. 7: Skeleton of Rabbit. B. 8: Skull of Rabbit. B. 9: Rabbit: Ribs, Sternum, etc. B. 10: Rabbit: Limb Bones. C. 11: Protozoa. C. 12: Earthworm: General Anatomy. C. 13: Earthworm: Transverse Section, etc. C. 14: Frog. D. 15: Green Algæ. D. 16: Leaf. (London: G. Philip and Son, Ltd.) Double Charts, 11*s*. 6*d*. Single Chart, 6*s*. 3*d*.

THE difficulty of finding English diagrams suitable for the teaching of biology in schools is a byword amongst teachers of the subject. Philip's series will do something to remove the complaint. They are diagrammatically accurate, bold in design and colouring (although a little crude), well lettered, and of a size (24 in. × 38 in.) suitable for all except large laboratories and class-rooms. The series of sixteen charts contains four illustrating Mendelian inheritance, although unfortunately none shows a simple case of dominant and recessive characters, six are of skeletons or parts of skeletons, four illustrate common zoological types, and two are botanical. In making a selection for this limited series the designers wisely chose subjects which do not readily lend themselves to blackboard illustration. The charts are mounted on cloth and may be obtained at the same prices dissected to fold in four, or varnished with a roller; varnished diagrams, however, are useless in many laboratories because of light reflections from the glazed surface.

Schicksalsstunde Europas:

Erkenntnisse und Bekenntnisse, Wirklichkeiten und Möglichkeiten. Von Karl Anton Prinz Rohan. Pp. 432. (Graz, Wien und Leipzig: Leykam Verlag, 1937.) 7 gold marks.

PRINCE ROHAN is not content to live on the reputation of a historic name: he has won himself a prominent place as a writer on political philosophy. At the beginning of his philosophical career, Prince Rohan stood for free international co-operation. But the drift of events during recent years has modified his attitude to the extent of subordinating everything to a fight against communism. In the present work, which deserves to be translated into English, Prince Rohan begins with Europe's inescapable burden laid on it by centuries of tradition. Delving into the heart of mankind, he traces its hesitations between atheism and the search for God. From all this emerges his picture of twentieth-century man—a being torn between a dozen conflicting tendencies, between Christianity, socialism, liberalism, fascism, nazism and communism. To him the threat of communism is so great that only a vigorous antidote will counter. Hence his justification of nazism and the importance of the idea of 'race' which permeates it. Though everyone will not agree with Prince Rohan's views, his exposition is worth attention, and few would fail to benefit from the reading of "Europe's Hour of Destiny".

The Clear Mirror:

a Pattern of Life in Goa and in Indian Tibet. By G. Evelyn Hutchinson. Pp. xi+171+13 plates. (Cambridge: At the University Press, 1936.) 8*s*. 6*d*. net.

IN the three essays which make up this volume, the author, a member in 1932 of the Yale North India Expedition under the leadership of Dr. H. de Terra, records some of his impressions of travel. Of these the first, "Spain at Sea", deals, as its title may suggest, with the voyage to India and the life of Goa, with its former colonial splendours; the second, "Paintings on a Fan", the fan being the plain country of the north Indian foothills, describes Ladakh and the temples, with their paintings and ritual dances of Leh; and the third, "Lakes in the Desert", is concerned with the more picturesque and imaginative aspect of physiographic conditions in the upper regions of the Indus Valley. The author has a keenly observant eye for form and colour, and within the limits he has imposed, his essays are vivid pieces of description.

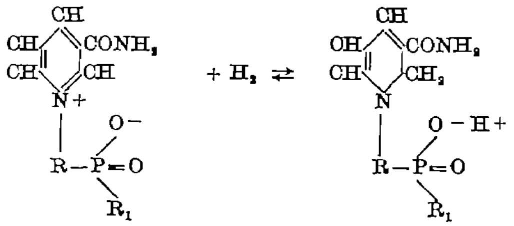
The Intermediary Reactions of Fermentation[*]

By Prof. Otto Meyerhof, For. Mem. R. S., Physiology Department, Kaiser Wilhelm Institute for Medical Research, Heidelberg

IN what way and by what mechanism is the sugar molecule transformed in the cell under anærobic conditions into its biological end-products, alcohol and carbon dioxide in the case of yeast, or lactic acid in the case of muscle? The different kinds of anærobic breakdown of carbohydrate are so closely related, the anærobic formation of lactic acid especially offers so many analogies to alcoholic fermentation, that the discussion of one will throw much light on the other.

Just as a cell-free yeast extract could be made according to the prescriptions of Buchner and Lebedew, so a glycolysing extract of muscle could be obtained and both systems could be divided further. The co-enzyme systems could be removed by dialysis and the protein residues could be fractionated in various ways. In addition to such fractionation, it is possible to suppress certain enzyme reactions by specific poisons, leaving others undamaged, and by other means to remove from further reaction certain intermediate products. At the end, one arrives at certain elementary or primary reactions by which, step by step, substances structurally adjacent are converted one into the other.

In these intermediary reactions, four different types are obvious. The most familiar type is oxidation-reduction. This oxidation-reduction is confined to three distinct reactions, which are connected by the cozymase of Harden and Euler. The chemical constitution and the function of this cozymase have been revealed by Otto Warburg during the past year. The cozymase was identified as diphosphopyridine-nucleotide, where the H_2-carrying group is nicotinic acid amide (scheme 1).



Cozymase. Cozymase—H_2.

R=Ribosephosphor. ac. R_1=Adenosine.

(1)

The reduction process consists of the conversion of acetaldehyde, which arises in fermentation, to alcohol. The oxidation has been achieved by O. Warburg with hexosemonophosphate; but in fermentation this monophosphate is not the molecule which reacts directly with cozymase but a more remote primary product. The oxidation process, which reduces the cozymase, consists of the conversion of triosephosphate (more exactly glyceraldehydephosphate) into phosphoglyceric acid. The oxidation-reduction consists of the *reduction* of aldehyde to alcohol, and the *oxidation* of phosphorylated aldehyde to phosphorylated carboxy acid. This is the oxidation-reduction in the stationary state of fermentation where acetaldehyde is already present as split product of pyruvic acid. In the beginning, during the so-called induction period, the phosphoglyceric acid arises by the dismutation of triosephosphoric acid alone, while simultaneously α-glycerophosphoric acid is formed as reduction product. This dismutation also is brought about by cozymase.

The yeast dialysate, designated originally as coenzyme of fermentation by Harden, does not contain only the cozymase, but several other constituents as well. One of these is a second coenzyme which also can be regarded as the dissociable active group of an enzyme, namely the phosphorylating coenzyme. This coenzyme is the so-called adenylic system. It consists of three parts: (*a*) adenylic acid (adenosinmonophosphate), (*b*) adenosindiphosphate, and (*c*) adenosintriphosphate.

The last two substances were discovered by K. Lohmann in our Institute. The transfer of phosphate is brought about by adenylic acid or adenosindiphosphate taking up phosphate, and adenosintriphosphate giving it off. The substance which accepts phosphate from adenosintriphosphate is hexose. It first becomes hexosemonophosphate and then hexosediphosphate, the well-known ester of Harden and Young. On the other hand, only one substance gives off phosphate. This is the precursor of pyruvic acid, phosphopyruvic acid. In splitting phosphopyruvic acid, the phosphate group is transferred to a sugar or hexosemonophosphate molecule, according to the following scheme (2).

A. 2 phosphopyruvic acid + adenylic acid = 2 pyruvic acid + adenosintriphosphoric acid

B. 2 glucose + adenosintriphosphoric acid = 2 hexosemonophosphoric acid + adenylic acid

$C = \frac{A+B}{2}$ phosphopyruvic acid + glucose = pyruvic acid + hexosemonophosphoric acid

D. phosphopyruvic acid + hexosemonophosphoric acid = pyruvic acid + hexosediphosphoric acid

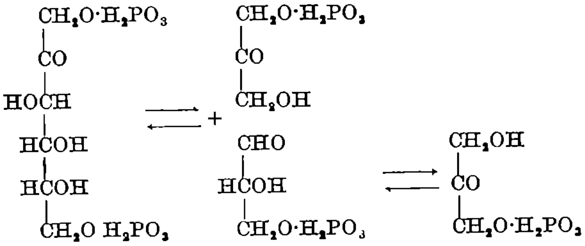
(2)

---

[*] Extracted from a lecture given at the staff meeting of the Rockefeller Institute for Medical Research, New York, on October 15, 1937.

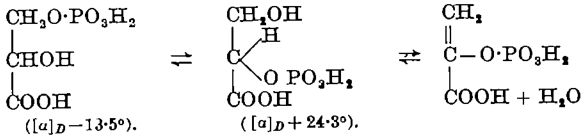
This chain of reactions goes very much faster than the direct splitting into pyruvic acid and inorganic phosphate, and is a typical example of transfer of phosphate.

The oxidation-reduction and the phosphorylations are the most important links of the reaction chain from the energetic point of view, but with these two types of reactions the series is not yet complete. If one removes all coenzymes by dialysis, such an extract is inactive towards hexose, also towards hexosemonophosphate, but not towards hexosediphosphate. In 1934, I found, together with K. Lohmann, that hexosediphosphate enters a very fast reversible reaction, namely hexosediphosphate ⇌ 2-dihydroxyacetonephosphate. Here the 6-C chain is split reversibly into 3-C chains. The closer investigation of this remarkable reaction revealed the fact that it must be separated into the two reactions given in scheme 3.



(3)

In the first reaction, one half of the molecule is converted into 3-glyceraldehyde-phosphate, synthesized by H. Fischer two years earlier. This 3-glyceraldehyde-phosphate is then largely converted into dihydroxyacetone-phosphate. In the opposite direction the two trioses react by enzymatic aldol condensation to form hexosediphosphate. The other reversible reactions described below are also independent of a coenzyme. In 1933 Embden discovered shortly before his death that phosphoglyceric acid is converted enzymatically into pyruvic acid and phosphate. The closer investigation of this Embden reaction taught us that here also a reaction chain occurs which must be formulated as in scheme 4.

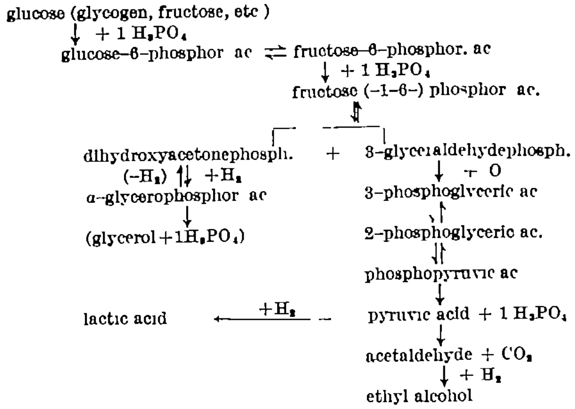


(4)

Between 3-phosphoglyceric acid, 2-phosphoglyceric acid and phosphopyruvic acid a reversible equilibrium exists. The conversion of the last into pyruvic acid is an irreversible dephosphorylation, as I have already stated.

In pursuing the further fate of the pyruvic acid we meet the fourth type of fermentation reaction, the breakdown of pyruvic acid into acetaldehyde and carbon dioxide by the well-known carboxylase of Neuberg. This carboxylase also has a dissociable group which was identified by K. Lohmann a short time ago as the pyrophosphate of aneurin (vitamin B_1).

I have put down all these intermediary products in scheme 5, where the chemically adjacent substances follow each other directly. Every substance is distinguished from the preceding one either by one phosphate group, one carboxyl group, one water group, an oxidative stage, or the neighbouring position of phosphate. Any other stable intermediates are, therefore, highly improbable.



(5)

Does this scheme also indicate the pathway by which in the stationary state the breakdown really proceeds? I can answer the question in the affirmative Some investigators claimed the hexosemonophosphate to be the reactive form of sugar, because it ferments more rapidly than does the Harden–Young ester. Some time ago I myself was also in favour of this opinion. On the other hand, the ester of Harden–Young was not popular in this respect, for the reason that it ferments very slowly and does not decrease during the rapid period of fermentation, but even accumulates, which seems strange for an intermediary product. Only in the past year have we succeeded in solving this paradox by the closer study of the so-called 'fermentation test' of Warburg and Christian.

These investigators have obtained from maceration juice of yeast two different fractions of protein partially purified, so-called *A*- and *B*-proteins which, together with the total system of coenzymes are able to decompose hexosemonophosphate in the presence of acetaldehyde into phosphoglyceric acid and pyruvic acid. (The carboxylase is removed by this fractionation.) Glucose alone and also hexosediphosphate alone remain practically unattacked in this fermentation test. It appeared as though hexosemonophosphate by the interaction of acetaldehyde would split into two oxidized halves, namely, pyruvic acid and phosphoglyceric acid. This finding contradicted all our experience, according to which the whole of pyruvic acid is derived from phosphopyruvic acid. The study of this fermentation test had an unexpected result: it could be proved with convincing evidence that the structural chemical sequence of substances is identical with the pathway of breakdown. Why, I should like to ask, can hexosemonophosphate be metabolized only with both protein fractions *A* and *B* together? This follows, as our experiments show, from the fact that the so-called *A* protein contains that enzyme which in co-operation with the adenylic system enables the phosphate transfer in equation *F* of scheme 6.

E. 1 hexosediphosphoric acid
$\upharpoonleft\downharpoonright$
2 triosephosphoric acid + 2 acetaldehyde + 2 glucose + 2 H_3PO_4
= 2 phosphoglyceric acid + 2 alcohol + 2 hexosemonophosphoric acid
F. 2 hexosemonophosphoric acid + 2 phosphoglyceric acid
= 2 hexosediphosphoric acid + 2 pyruvic acid

G = *E* + *F* 1 hexosediphosphoric acid + 2 acetaldehyde + 2 glucose + 2 H_3PO_4
= 2 pyruvic acid + 2 alcohol + 2 hexosediphosphoric acid
H = *G* + carboxylase 1 hexosediphosphoric acid + 2 glucose + 2 H_3PO_4
= 2 CO_2 + 2 alcohol + 2 hexosediphosphoric acid

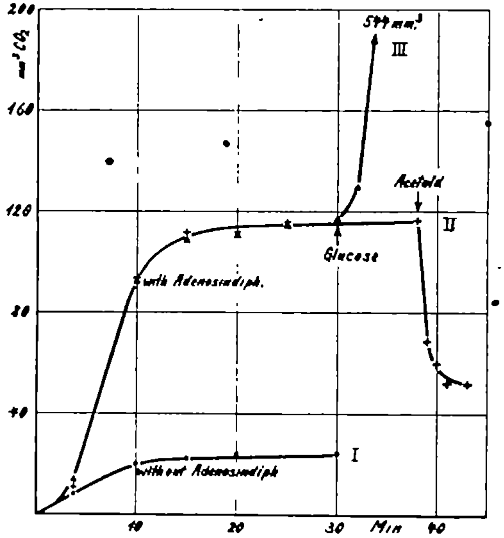
(6)

If no hexosediphosphate can originate, no fermentation takes place because hexosediphosphate is the only source of triosephosphate. Accordingly, a fermentation comes about with *B*-protein alone, if one starts with a mixture of glucose and hexosediphosphate, since now the hexosediphosphate can be decomposed into triosephosphate (*E* of scheme 6). Two molecules of triosephosphate, which originate from the rapid breakdown of one molecule of hexosediphosphate, are oxidized by acetaldehyde to phosphoglyceric acid; the acetaldehyde is reduced to alcohol, while simultaneously two molecules of glucose are esterified to hexosemonophosphate. On subsequent addition of the phosphorylating enzyme, that is, the *A* protein, the above-mentioned reaction *F* will be obtained. Hexosemonophosphate takes up phosphate from phosphopyruvic acid which originates from phosphoglyceric acid. When we sum up equations *E* and *F* and consider that two molecules of triosephosphate are equal to one molecule of hexosediphosphate, we obtain the balance equation *G* of scheme 6. In this balance, hexosemonophosphate and phosphoglyceric acid are cancelled as intermediates, since they appear on both sides. Now, for the turnover of two molecules of glucose we get one molecule of hexosediphosphate in addition; but while equation *E* indicates a stoichiometrical reaction, this is no longer the case with equation *G*. Hexosediphosphate increases autocatalytically and always reacts anew by way of triosephosphate according to equation *E*, until another component, for example glucose or inorganic phosphate, is completely consumed.

Equation *G* is nothing but the fundamental reaction on which the Harden–Young equation is based. In our case the carboxylase was removed by fractionating the proteins. When we add this carboxylase, by which the pyruvic acid is split into acetaldehyde and carbon dioxide, we arrive at the total balance *H* of scheme 6. Now the acetaldehyde also is cancelled in the balance and we obtain the Harden–Young equation itself by merely removing one molecule of hexosediphosphate from each side. It is, however, advisable to leave this hexosediphosphate as it is in equation *H*, because this emphasizes that really hexosediphosphate is converted into alcohol and carbon dioxide, while glucose represents the acceptor of phosphate. In the balance, according to the Harden–Young reaction, free sugar disappears and hexosediphosphate accumulates. However, according to the mechanism it is in fact entirely different, for the hexosediphosphate is the mother substance of the triosephosphate which reacts directly with cozymase, while glucose is being converted into diphosphate by way of hexosemonophosphate, according to equations *E* and *F*. I remind you of a finding obtained twenty years ago, that maceration juice free from autofermentation does not decompose sugar, without a trace of hexosediphosphate having been added in the beginning. This is the hexosediphosphate on the left side of equation *H*.

In respect to the fermentation of hexosemonophosphate studied by Warburg, it can also be shown that the mechanism is the same. The hexosemonophosphate is at first converted into hexosediphosphate by taking up phosphate, and equations quite analogous to those demonstrated are valid. As a matter of fact, the pyruvic acid which appears in this fermentation of hexosemonophosphate has derived from phosphopyruvic acid by the transfer mechanism of phosphate, as shown in equation *F* of scheme 6.

It is always the triosephosphoric acid which reacts directly with cozymase. But this reaction proceeds slowly by itself, and is rapid only in the presence of a substrate functioning as acceptor of phosphate. A most convincing demonstration can be given by substituting creatine for glucose in the fermentation system of hexosediphosphate. Creatine, as is well known, is not present in yeast, but it is of fundamental importance in the lactic acid formation of muscle as acceptor of phosphate. If one adds to the *B* protein of Warburg, in addition to the different coenzymes, hexosediphosphate and creatine and a little of the specific enzyme which enables the phosphate transfer from adenylpyrophosphate to creatine, hexosediphosphate will now be decomposed into pyruvic acid as rapidly as in the presence of glucose.



Manometric determination of reduction of cozymase by triosephosphoric acid in presence of *B*-protein. Carbon dioxide liberation from sodium bicarbonate by H+ of reduced cozymase and H+ of phosphoglyceric acid.

The specific relation between the oxidation-reduction and the uptake of inorganic phosphate, which has also impressed other investigators, can be traced to a coupling of the reduction of cozymase and the phosphorylation of adenylic acid or adenosindiphosphate to adenosintriphosphate. When we omit acetaldehyde from our system and employ triosephosphate and cozymase in equivalent amounts, only a very slow reaction takes place; but this reaction is accelerated enormously as soon as either a larger quantity of adenosindiphosphate or an excess of glucose with a trace of an adenylic compound is added. In the accompanying diagram the course of this conversion is demonstrated.

The measurements were made with manometric technique. The second curve is with a large amount of adenosindiphosphate. The steep upward branch of the curve shows the effect of adding glucose as indicated. This interacts with the adenosintriphosphate formed by phosphate transfer to adenosindiphosphate. The curve sloping downward shows the effect of adding acetaldehyde, by which the reduced cozymase is reoxidized. In addition to this manometric method, the hydrogenation of cozymase can be measured spectrographically. As discovered by O. Warburg, the reduced cozymase has a broad absorption band at 340 mμ, which is lacking in the oxidized form. From the breadth of the band the amount of reduced cozymase can be calculated. Thus, by different methods one arrives at the equations in scheme 7.

J. 1 triosephosphate + 1 Cz + 1 adenosindiphosphate + H_3PO_4
= 1 phosphoglyceric acid + 1 CzH_2 + 1 adenosintriphosphate
K. 1 adenosintriphosphate + 1 glucose
= 1 adenosindiphosphate + 1 hexosemonophosphate

L. = *J* + *K.* 1 triosephosphate + 1 Cz + 1 Glucose + 1 H_3PO_4
= 1 phosphoglyceric acid + 1 CzH_2 + 1 hexosemonophosphate

(7)

Always we obtain an equivalence between esterified phosphate, reduction of cozymase, and formation of phosphoglyceric acid. The profound cause for this coupling between the adenylic system and the reduction of cozymase (equation *G*) remains to be explained.

Basin Cultivation in the United States

By Lois Olson, Soil Conservation Service, United States Department of Agriculture

IN an article entitled "Soil Conservation in Tropical Africa" (NATURE, 141, 268–270; Feb. 12, 1938), Dr. L. Dudley Stamp described a basin type of cultivation that is in practice in Northern Nigeria. In conclusion he states, "If America could invent a plough which will imitate the Nigerian system by replacing the long furrow by a series of isolated elongated basins, one at least of her major problems in the dry lands of the Middle West might be solved". Actually, the principle of basin cultivation described by Dr. Dudley Stamp has been the subject of experimentation in the United States for the last ten years, and to-day several basin cultivators are on the market and in use by farmers in various parts of the country.

So early as 1927, Mr. C. T. Peacock, a Colorado ranch owner, developed a basin lister* which proved satisfactory on his land. The damming attachment consisted of a drag which followed the cutting blade. At intervals the drag was lifted,

---

* A double mould board plough.

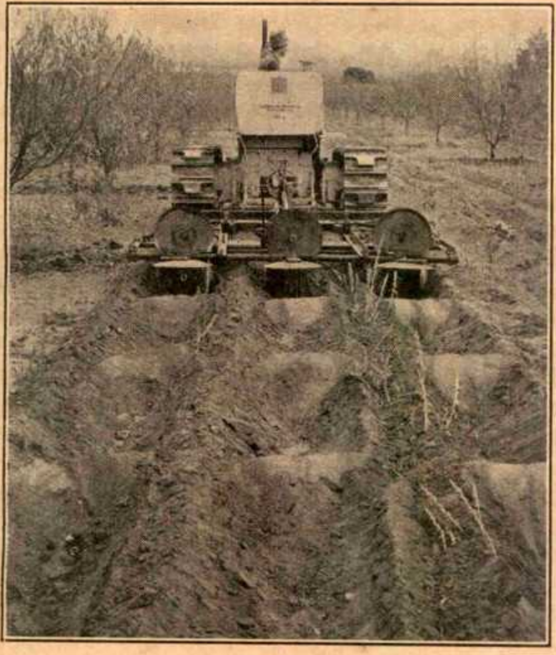


Fig. 1.
THE BASIN LISTER IN OPERATION IN A CALIFORNIA ORCHARD.

leaving dams across the furrows. A patent was obtained in 1931. In the spring of this same year, Mr. R. H. Davis began work on a hole-digging cultivator at Hays, Kansas, and by the autumn of the year an improved model of the implement was sent to the Soil Erosion Experiment Station, Pullman, Washington, for testing. Although the machines were operated on entirely different principles, they served much the same purpose in the semi-arid sections of the country. The cultivator, which dug holes of about ten-gallon capacity, was designed primarily to retain moisture and check erosion on fallow land but later proved effective in orchards, particularly in California. Because of the pockmarked appearance of the fields, it was commonly known as the 'waffle' cultivator, and during 1931 it received considerable attention in the Press. Almost simultaneously, but completely independently, a machine which accomplished the same ends was designed in Hawaii.

In 1934 experimentation was begun on another type of basin lister at Ames, Iowa, by the Bureau of Agricultural Engineering, in co-operation with the State Experiment Station. This work was performed under the direction of J. B. Davidson, C. K. Shedd and E. V. Collins. A rotary, paddle-like attachment was used for constructing the dams.

The basin lister has several advantages over the hole-digging cultivator. The furrows, being larger than the holes, retain a larger amount of water and fill with sediment less readily. Most farmers in the Great Plains area already own listers, and the damming unit may be purchased separately and attached to an ordinary lister. Plans and specifications for the construction of a home-made damming attachment are also being distributed by the Fort Hays branch of the Kansas Agricultural Station.

The use of the basin lister raises several practical problems. If it is used for corn, the water retained in the furrow may cause the soil to form a crust on the top. If so, the young shoots may not be able to break through and an imperfect stand results. After the corn has started growth, the subsequent cultivations tend to break down the ridges between the furrows, and during the last cultivation the ridges are practically destroyed. After harvesting the corn, the land is consequently left unprotected until it is again cultivated in the spring. This means that the soil has no protection during three fourths of the year. In other circumstances dams that have been left standing present obstacles to subsequent cultivation, but several simple types of 'dam busters' have already been devised.

The space occupied by the dams reduces the water-holding capacity of the furrows, the reduction being in proportion to the space occupied by the dams. The spacing of the dams would necessarily vary with the amount of rainfall and

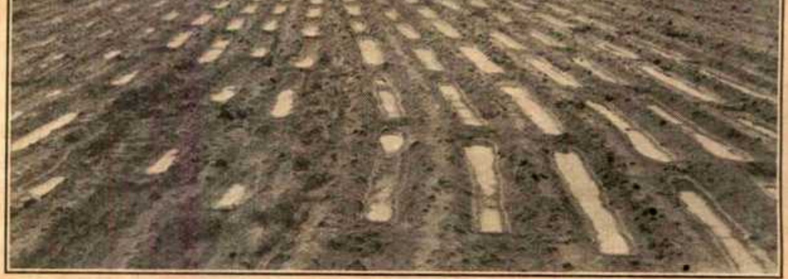

Fig. 2.
BASIN LISTING NEAR HAYS, KANSAS.

with the position of the furrows. The closer they approach to the contours the longer the furrows may be and the greater will be their storage capacity.

As yet the basin cultivator has not been adapted to grains such as wheat, since there is no seeding device capable of planting the seeds at the different depths that would be required on a field prepared by a basin cultivator. The objections advanced, however, are not serious enough to prevent the use of the basin lister for other crops or to discourage further experimentation.

Science and Industry at the Empire Exhibition, Glasgow

THE exhibits in three of the large exhibition halls in the United Kingdom Government Pavilion at the Empire Exhibition, Glasgow, opened by H.M. the King on May 3, have been arranged by the Department of Scientific and Industrial Research in close collaboration with industry. The aim of the halls is to show the relationship now existing between science and industry, and the part which science has played in the development of British industry. The theme is illustrated by the three great national industries of coal, iron and steel, and shipbuilding—one of the exhibition halls being devoted to each of these industries. The subjects of the halls were chosen on the advice of a committee which included some of the greatest industrial leaders in the country.

In telling the story of the place which science is taking in modern industry, practically every device of modern display has been employed to make the exhibits attractive and interesting. In this work the Department has had the help of a distinguished display expert.

Everywhere the visitor finds colour and movement. Complicated processes are simplified and traced out for him by moving lines of light. Where possible, working models are used, and elsewhere essential points are explained by short cinema films introduced into the various sections of the exhibit. The meaning underlying the halls is made plain by large murals. Many of the exhibits are demonstrated by members of the staff of the Royal Technical College, Glasgow. A novel feature of the halls is, that in the sections where a demonstrator is not provided, the various exhibits are explained in conversational tones by loudspeakers radiating the story of the section and directing attention to the various points. For this purpose a new system of sound recording employing a narrow strip of film is being used.

The first of the three industrial research halls is devoted to coal. The most prominent single exhibit in the hall is a large working model of a coal mine more than 200 square feet in area and fifteen feet in height. This has been provided for the Pavilion by the Mining Association of Great Britain, and is probably the finest model of its kind in the world. Both underground and surface workings are illustrated in detail. The latest methods of winning coal are demonstrated and near by are exhibits illustrating the work of the Safety-in-Mines Research Board and the Miners' Welfare Committee. There are also sections dealing with the preparation of coal for the market, which show that coal as supplied to the consumer to-day has ceased to be a crude raw material and has become more and more a semi-manufactured article. Entering the hall, there is a section dealing with the origin of coal. Here there is a large representation of what a coal forest looked like some two hundred million years before the appearance of man. A short cinema film shows how the debris of such a forest was converted into coal seams. The immense varieties of British coal are illustrated by a number of pillars cut from various coal seams. In the next section of the hall the work of the National Coal Survey is illustrated, and the way in which the immense amount of knowledge now available concerning the properties of coal is being used for its better utilization. The next section deals with the great advances which have been made in the use of coal for steam generation both in large power stations and in smaller industrial plants. Here, for example, it is shown that the amount of electricity which can be obtained from a ton of coal has increased by more than 60 per cent in the last twelve years and that, in addition, improvements in electric lamps and other appliances enable electricity to be used more economically. An interesting display shows the products of combustion in super-power station practice, in good and bad industrial practice, and in domestic heating. Something of the latest researches in domestic heating which are now being carried out is also illustrated.

The other side of the hall is devoted entirely to an exhibit prepared by the British Gas Federation dealing with the carbonization of coal in gasworks, coke ovens and low-temperature carbonization plants. The whole process of the treatment of coal and also many of the by-products produced are shown. The essential parts of the various plants are represented, and the course taken by the coal into these is traced by moving light. Light of a different colour shows the passage of the gas through the various stages and the methods by which impurities are extracted from it and converted into valuable products. In front of these diagrams are scenes showing the industries in which these by-products of coal are used, and below these again are fascinating models showing the finished articles which coal has helped to make. The centre of the hall is taken up by a large section illustrating the modern use of coal as a raw chemical material. Various processes for obtaining oil from coal are illustrated here, and it is shown how the gases produced by passing steam over red-hot coke or coal can be synthesized into motor spirit, industrial alcohol and other products. The use of coal as a raw material in the carbide industry, in the production of active carbon and in the making of electrodes is also illustrated.

In the Iron and Steel Hall the visitor will find a huge model of a blast furnace more than thirty feet in height. The furnace itself is made in glass and reveals the red-hot charge within and the molten iron apparently running into the pig beds. The right-hand side of the hall is devoted to the production of iron and steel from the ore to the finished product. To enable the layman to appreciate some of the research problems involved, an attempt has been made to show something of what goes on inside the steel furnace. This has been done by the use of moving coloured models partly made in glass. They indicate, for example, the importance of the heat resistance of the brick linings of the furnace. Industry spends £3,000,000 a year in the replacement of these, which represents 5*s.* of the cost of every ton of steel made. Here is obviously a problem of research, in which, by the way, great progress is being made. The importance of controlling the various processes by scientific instruments is brought out and the ways in which science is helping towards improvements in efficiency and reduction of waste in every form.

Two sections of the hall deal with the microscope and X-rays. The use of the microscope to reveal the inner structure of metals is demonstrated, together with the way in which such knowledge is being used to produce stronger but lighter steels, besides steels possessing special properties. In the X-ray section a powerful equipment for X-ray analysis is shown working, and the visitor learns how, by this means, the physicist can deduce the actual arrangement of the atoms from which the crystals seen in the microscope are built up. Both the use of the microscope and the X-ray apparatus is demonstrated by the staff of the Royal Technical College, Glasgow.

Finally, the way in which steel is used for various engineering purposes is illustrated and an attempt is made to show the visitor how an engineer would select a steel for a particular job and the kind of forces the steel would have to withstand. Progress in constructional steels, for example, is illustrated by a series of model bridges of increasing span constructed of cast iron, mild steel and alloy steel. The load on the bridges consists of a model train. The visitor is reminded of the immense savings, amounting to many millions of pounds a year, resulting from the use of improved steels produced by scientific research, and of the way in which these steels are enabling what were once the luxuries of the few to be brought within the reach of millions. Just before the visitor leaves the hall, an interesting small section directs his attention to the increase in value of iron resulting from research and craftsmanship, which shows that iron in the form of iron ore is worth about 34*s.* a ton, while in the watch-spring, for example, it is worth perhaps £4,000,000 a ton.

In the Shipbuilding Hall the subject has been treated in three parts—the hull, the engines and navigation. Improvements in the lines of the hull have come about as the result of 'tank' research. There is a working model of the famous Yarrow Tank and the workshops associated with it at the National Physical Laboratory. While such a model brings out the length of the modern tank, it can convey very little idea of the actual type of the model hull used in the work or of the instruments employed. Accordingly a 16 ft. wax model of a hull fitted with the necessary recording instruments is also shown. Recent research on the phenomenon of cavitation is illustrated by a propeller-tunnel in which a propeller is shown running under conditions which produce cavitation.

Turning to the marine engine, working models of three of the latest types of turbine, reciprocating engine, and oil engine are shown. In another exhibit the development is traced of the steam engine and its efficiency from the time of Watt to the present day.

The results of research in shipbuilding are summed up in one section of the hall. Here it is shown that the fuel consumption of an ordinary cargo vessel of, say, 9,000 tons steaming at 10 knots, has been reduced by nearly half in the last fifteen years as the result of research. How this remarkable result has been brought about is shown by a representation of a cargo vessel of fifteen years ago, which fades before the eyes of the onlooker to the same type of ship as would be built to-day.

One of the most popular exhibits in the hall is a very realistic ship's bridge carrying the wheelhouse and chartroom of a cargo liner. Practically all the navigating instruments found on such a vessel, including the gyro-compass, the echo depth-sounder and the wireless direction-finder are arranged so far as possible to simulate working conditions. The visitor is able to handle these instruments and to have their principles explained to him by the 'captain', the 'chief officer' or the 'quartermaster'. Elsewhere in the hall the principles underlying some of these instruments are demonstrated in other ways. In this section also there is a fascinating display illustrating a cathode ray direction-finder which gives the bearings of a distant station instantaneously. Another exhibit which is proving very popular is the wireless office of a British destroyer manned by naval ratings.

The large mural, 1,500 ft. square, over the exit of the hall is a striking example of the industrial co-operation which has made the exhibits possible. On this mural are displayed silhouettes of every vessel of more than 100 tons gross launched from British yards last year; they include liners, tanker vessels and smaller craft, besides warships of every description. Some four hundred ships, of capital value £46,000,000, are represented according to the town in which they were built. Every ship-building firm in the country has contributed to this remarkable feature by supplying silhouettes of the ships built in its yards.

Obituary Notices

Colonel Marcuswell Maxwell

COLONEL MARCUSWELL MAXWELL, who died suddenly in a Nairobi nursing home on April 21, was one of the most successful photographers of wild life in East Africa, his photographs of lions, elephants, giraffes, rhinoceroses and other big game being some of the best ever taken, while his photographic studies of the eastern gorilla have never been surpassed. He shared with his namesake, Marius Maxwell, the distinction of being not only a photographer but also a photographic artist in that nearly every exposure he made was a picture.

Maxwell's photographs of East African big game have from time to time appeared in the pages of *The Times* and were published in book form, in two volumes, by *The Times* in 1930. One of these volumes, entitled "Elephants and Other Big Game Studies", contains eleven magnificent photographs of the African elephant, the majority of which were taken at close quarters. These are followed by photographs of black rhinoceros, waterbuck, hunting dogs, hyaenas, impala, eland, zebra, giraffe, wildebeest and vultures. The other volume, entitled "Big Game Photographs", commences with a series of photographs of the well-known Serengeti lions, among them some of the most amazing close-ups of these large carnivora that have ever been secured. There is also an interesting study of a lion climbing a tree, showing that these animals do occasionally exhibit arboreal habits. In this volume, there are also photographs of a rhinoceros accompanied by tick-birds, giraffes in the open, a wonderful study of buffaloes in cover, two wart-hogs at home and a general view of waterbuck at a water-hole.

It is a sad coincidence that death should have overtaken both Marcuswell and Marius Maxwell, two of our most prominent animals photographers. They were not related, but their names and photographic work being so similar frequently led to confusion between the two. This was accentuated by the fact that, in addition to both photographing wild life in Kenya Colony, they both visited the Birunga range of volcanoes in the eastern Belgian Congo in the hopes of photographing the eastern gorilla. Here Marcuswell was more successful than Marius, the latter encountering abnormally bad climatic conditions even for these equatorial forests. Some of Marcuswell Maxwell's photographs of gorillas will never be bettered; he had the good fortune to come up close to an old male gorilla and his family, and without very much interference from the ground vegetation was able to take some excellent pictures.

Zoological science, naturalists and sportsmen have lost a very ardent worker in the death of Marcuswell Maxwell, and he leaves a blank which will be very difficult to fill.

GUY DOLLMAN.

Prof. J. E. Johansson

PROF. J. E. JOHANSSON, of Stockholm, died on March 31, at seventy-six years of age. Johansson was professor of physiology at the Caroline Institute in Stockholm from 1901 until 1927. His first degree was in physics and mathematics. He then studied physiology with Holmgren in Uppsala, and in 1889 he worked with Ludwig in Leipzig. In 1890 he was awarded his M.D. degree for a thesis on the splanchnic nerves and was appointed reader in Tigerstedt's laboratory at Stockholm. From 1890 until 1908, he carried out his well-known researches on metabolism, particularly in connexion with muscular exercise. From 1908 onwards, however, his spare time was chiefly occupied with various activities on behalf of the Swedish Government. He was chairman also (until 1926) of the Medical Nobel Committee, and the high standard which he maintained gave him an enormous amount of work in studying the claims of persons proposed for the Nobel Prize in physiology and medicine.

Johansson's works on social medicine are numerous. He revised and reformed the medical statistics of Sweden. As a member of a Government committee he worked very hard for the abolition of regulated prostitution in Stockholm and published a book on the subject "Sur la réglementation à Stockholm" 1912. The majority did not take his view and he had to fight alone, which he did with great vigour. In 1920 the Swedish Parliament passed a law which abolished it.

For many years, Johansson was a member, and later president, of the board for the Royal Gymnastic Central Institute, where he worked hard for the reorganization of the old institute and for the erection of a laboratory for the physiology of muscular exercise. It is hoped that the Swedish Government will provide for this shortly. He was chief adviser to the Board of Nutrition during the Great War.

Johansson was greatly beloved by his students and colleagues, and was a popular and well-known figure at international gatherings. He was president of the International Congress of Physiology at Stockholm in 1926 and chairman for many years of the Permanent International Committee of the Congresses. He attended the Harvey celebrations in London in 1928. He was an honorary member of the Physiological Society. For many years until his death he was chairman of "Idun", the well-known society of men of science, letters and art in Stockholm. He was an honorary member of the Medical Society of Sweden, honorary senator of the Polytechnical High-school of Dresden, and a commander of the order of the Belgian Crown. He received the degree of LL.D. from the University of Edinburgh in 1923.

Johansson's brothers were gifted men. The eldest is a mining engineer, the second became the youngest judge in Sweden, the third was a clergyman and the fourth, Harold, a well-known geologist. His sister was the wife of the famous Swedish chemist Arrhenius. Johansson never went to school, but was educated by his elder brothers and entered the University at the age of fourteen. Although a bachelor, his home was always full of young people, nieces and nephews, who nearly all of them spent years there when studying in Stockholm.

Johansson's scientific papers are published in various physiological journals, particularly the *Skandinavisches Archiv für Physiologie*, and in the text-books of Abderhalden, Zuntz and Loewy, and Hammarsten.

A. V. H.

Dr. Hermann Augener

DR. HERMANN AUGENER, of the Hamburg Museum, died on April 5 in his sixty-sixth year. The son of a merchant, he was born in Hamburg on October 2, 1872, and after doing his schooling in his native city went to Gottingen and afterwards to Munich to continue his scientific studies. Of independent means, he might have done anything he chose, but he decided to devote his life to marine zoology. He spent some time at the Zoological Station at Naples, and from there went as an assistant to the Zoological Institute of the University of Gottingen, where he remained for several years. His next and final move was back to his native Hamburg, where he became an unpaid, voluntary worker at the Hamburg Museum.

Augener was a specialist on the marine annelids or Polychæta and became a leading authority on the group. Most of his work was of a faunistic nature, and he did much not only to extend our knowledge of the group, but also to impose order upon its classification. He had great learning and an extraordinary capacity for accurate detail. He published about forty papers, many of great length, and among these the more notable are his work on the West Indian Polychætes, his volume on the Polychæta in the "Meeresfauna West-Afrikas", his contributions to Michaelsen and Hartmeyer's "Fauna Sudwest-Australiens" and his papers on the Polychæta of New Zealand. At the time of his death, he was engaged on the Polychæta of the Dutch *Siboga* Expedition.

After the Great War, Augener had a severe struggle against poverty and ill-health. Married and with a family, he was left almost destitute by the collapse of the mark, but happily the Hamburg Museum came to his rescue with a small grant which enabled him and his family to live. In middle life he developed grave defects of hearing and eyesight. In fact, for about the last twenty years he was more than half-blind, and how, his eyesight being what it was, he carried on with his fine microscopic work, was known only to himself. That he did so may justly be described as heroic. He ploughed a narrow furrow to the end, and was without the reward of any public appreciation of his work, which was recognized only by his co-specialists.

Augener's is a gallant story. C. C. A. M.

WE regret to announce the following deaths:

Prof. Max Neissen, professor of bacteriology and hygiene in the University of Frankfort-on-Main from 1914 until 1933.

Prof. P. A. Ross, professor of physics in Stanford University, who carried out work on X-ray spectroscopy, on March 20, aged fifty-four years.

Prof. L. W. Stern, professor of psychology in Duke University, formerly director of the Psychological Institute in the University of Hamburg, known for his contributions to child psychology, on March 27, aged sixty-six years.

Prof. W. T. Taggart, emeritus professor of chemistry in the University of Pennsylvania, on April 11, aged sixty-six years.

Prof. J. Thienemann, founder of the well-known ornithological station at Rossitten, who inaugurated the system of bird ringing, aged seventy-four years.

Prof. R. Verneau, honorary professor in the Muséum d'Histoire naturelle, professor of prehistoric anthropology in the Institut de Paléontologie humaine, on January 7, aged eighty-six years.

News and Views

Sir Leonard Rogers, K.C.S.I., C.I.E., F.R.S.

THE award by the Royal Society of Tropical Medicine of the Manson Medal to Sir Leonard Rogers will be felt by all to be a fitting recognition of outstanding contributions not only to tropical medicine in general, but particularly and almost uniquely to the practical application of therapeutic measures in the treatment of some of the most important major tropical diseases. As a result of his studies of biochemical and other changes in cholera, that most dread and dramatically fatal of all tropical diseases, Sir Leonard Rogers introduced the use of hypertonic saline injections at a time when such forms of treatment were little used. Further, to his untiring energy in directing attention to the necessity of taking active steps to combat the critical stage of the disease by this and other methods, many advances in the treatment of cholera owe their origin. The introduction by Rogers of antimony treatment of kala-azar in India, and his early efforts to improve the form of administration of the drug as well as to extend its application, was very largely responsible for later great advances in the treatment of this disease by organic antimonial preparations and for the remarkable developments which were later introduced for combating kala-azar on a large scale in India. By his insistence on the value of emetin in amœbic dysentery and by his introduction of the soluble salts of emetin, he very greatly stimulated the use of this valuable drug in the treatment of amœbic dysentery in all parts of the tropics. It was also his unflagging interest and insistence on the treatment of leprosy that led to so much attention being directed to the gynocardates, now widely used. Among contributions of a more academic type may be mentioned the discovery of the flagellate stage of the parasite of kala-azar, early researches on malaria and studies on the epidemiology of cholera. To the energy and initiative of Sir Leonard Rogers must also be ascribed the establishment of the Calcutta School of Tropical Medicine, the first large institution of the kind in the tropics.

Prof. A. Smithells and Salters' Institute Fellows

IN appreciation of advice and assistance rendered by Prof. Arthur Smithells while director of the Salters' Institute of Industrial Chemistry from 1922 until his retirement last year, a group of fellows of the Institute has made a presentation to him of a set of silver beakers suitably inscribed. Subscribers to this token of gratitude and affection were, with one or two exceptions, limited to those who held fellowships during Prof. Smithells' term of office as director. The Institute is maintained by the Salters' Company and has two main activities: training of selected graduates in applied chemistry, by means of fellowships, in Great Britain or abroad, and assistance by means of grants for fees and books to young men employed in chemical works who are attending evening classes. To the selection of the fellows, Prof. Smithells gave much thought and attention, and already many of them are filling important posts in chemical industry, this being the object for which the Company maintains the fellowships. He devoted also a very sympathetic consideration to those who were awarded grants, having regard to all the circumstances of the applicants, who are analogous to the apprentices of former days in whom the City companies took a living interest. About fifty of the former fellows who were selected during Prof. Smithells' time, as mentioned above, have now testified to their regard for the former director, and for the help he gave them in the important stage between the university and entrance into industry, by the recent presentation to him.

Disorderly Molecules and Refrigerating Engineering

SIR FRANK SMITH in his James Forrest Lecture to the Institution of Civil Engineers on May 3 pointed out that in recent years very low temperatures (that is, great reductions of molecular motion) have been attained, and the properties of materials at very low temperatures have been studied. The corresponding advance in engineering technique has resulted in the development of refrigerating engineering. The Joule-Thomson effect, whereby the work done in separating the molecules of a gas allowed to expand from a high pressure results in the gas being lowered in temperature, is used in many commercial processes for cooling gases, and in some cases for liquefying them. In order to obtain pure gases from air, the process of rectification is employed. The process depends on the fact that when equilibrium exists between a mixture of two liquids and the vapour it gives off, the composition of the vapour is always different from the composition of the liquid if the two liquids in the mixture have different boiling-points. For example, oxygen boils at 90° K. and nitrogen at 77° K., and when equilibrium exists between liquid air and the vapour above, the vapour contains about 7 per cent of oxygen and 93 per cent of nitrogen. The separation of oxygen and nitrogen by rectification is therefore carried out by allowing liquid air to drop slowly into liquid oxygen; the vapour given off by the latter condenses as it comes into contact with the drops, while part of the nitrogen in the drops simultaneously evaporates, and if the drops are sufficiently small and fall very slowly, all the nitrogen evaporates before the drops reach the vessel containing liquid oxygen. The process is continued, with the result that the gas becomes steadily richer in nitrogen. Other gases can also be extracted from the air by low-temperature separation.

Westinghouse Research Fellowships

THE Westinghouse Electric and Manufacturing Co., of Pittsburgh, Pennsylvania, has established ten 'post-doctorate' fellowships for research in physics, including chemical physics and physical metallurgy, to enable investigators to carry on their work at the Westinghouse Research Laboratories in East Pittsburgh. Five fellows have been appointed for 1938–39, and five more will be appointed in each succeeding year. The objects of the Company in establishing the fellowships are: "(1) To make a worth-while contribution to the development of the fundamental sciences on which modern industry is based. The Company feels that all research leading to a better understanding of the nature of matter and energy will ultimately prove valuable to technology even though its immediate field of application is not apparent. (2) To enable a group of able investigators to become familiar with the scientific problems confronting the electrical industry. It is felt that this contact will be of great value whether the men turn to industrial research or to academic work after completion of their fellowship period." Fellows will devote their entire time to work on their research projects, and will be under the general supervision of Dr. E. U. Condon, associate director for the programme of fundamental research. It is expected that they will also participate actively in the seminars and colloquia held at the Laboratories and in the neighbouring institutions of higher education. Appointments are made for a period of one year and a fellow is eligible for one reappointment for a like period. The salary is 2,400 dollars a year.

THE names of the first five Westinghouse Research Fellows, chosen from fifty applicants, are: Robert O. Haxby, University of Minnesota. Mr. Haxby has been a graduate student in physics for the last four years, and has participated actively in the nuclear physics research in the University of Minnesota. He will join the group which will carry on research in nuclear physics using the large high-voltage generator now being built in East Pittsburgh. John A. Hipple, Princeton University. Mr. Hipple has been a graduate student in physics at Princeton during the past four years, where he has worked with Prof. Walker Bleakney. He will design a large mass-spectrograph of high resolving power for studies in molecular structure in the Westinghouse Laboratories. Sidney Siegel, Columbia University. Dr. Siegel has carried out researches on elastic and magnetic properties of metals under the direction of Prof. S. L. Quimby. He hopes to develop methods of growing single crystals of pure metals and of alloys which show order-disorder transitions to study how the elastic properties of alloys depend on the arrangement of the atoms in the crystal lattice. W. E. Shoupp, University of Illinois. Dr. Shoupp is at present an instructor in physics at the University of Illinois, where he is actively engaged in studies on nuclear physics with the Illinois cyclotron. In addition to his work in nuclear physics, he has made several contributions to extreme ultra-violet spectroscopy as a collaborator of Prof. P. G. Kruger. At the Westinghouse Laboratories, he will continue studies in nuclear physics, working with Dr. W. H. Wells on the high-voltage generator. W. E. Stephens, California Institute of Technology. Mr. Stephens has done work in nuclear physics in the Kellogg Radiation Laboratory in Pasadena, where he studied the production of neutrons by bombarding boron and nitrogen with high-energy deuterons. He has also worked on the development of a new type of high-voltage discharge tube. In East Pittsburgh he will continue his researches on nuclear physics with the large generator at the Westinghouse Laboratories.

Bronze Age Hoard from Bognor

A bronze founder's hoard, which is dated at the early part of the first millennium B.C., has been brought to light at Flansham, near Bognor Regis. The find was made at a depth of about four feet at a point in Hoe Lane, a deep and ancient track now a lane, where it was joined by a new drive in course of construction. The objects discovered were distributed among several owners, but have been brought together again to be described by Mr. S. E. Winbolt in *The Times* of May 9. With six bronze implements were twenty-two lumps of copper, weighing 14 lb. Some round pieces of copper indicate a diameter of six inches for the complete cake, which would appear to have been cast in a crucible with a slightly concave bottom. This hoard is evidently the stock-in-trade of a bronze founder, such as has been discovered not infrequently in Britain. Mr. Winbolt recalls that a similar hoard was found in the course of road construction at Bognor some twelve years ago. The implements found with the copper are two socketed and looped celts, with square-mouthed socket openings, cast with a core, two socketed gouges, the top of a V-type sword with rivet holes, and the side of the top of a carp's tongue sword with a very sharp edge, which is compared with those of the Addington (Kent) and Beachy Head deposits. All may be dated at about 1000–750 B.C., and are probably a native product, though showing the influence of Spain and north-west France. It is to be noted that, as usual, there are no traces of tin with the copper. It is suggested that this, as well as the other and slightly earlier Bognor hoard, may have been abandoned or temporarily hidden, on account of the difficulties of a journey arising from the marshy character of the ground in this neighbourhood at the period.

By-product Coking

ON March 17, G. W. J. Bradley, in a paper presented to the Institute of Fuel, briefly reviewed the history of the coking industry from its inception at the beginning of the eighteenth century to the present day. This development has gradually culminated into a tendency for the industry to split into two sections, the section connected with iron and steel works and regarded as an auxiliary part of steel works technique and the section situated at the collieries. During the years 1934–37 orders have been placed by British steelworks for plants to carbonize approximately six and a half million tons of coal per year. This figure is equivalent to one third of the total carbonizing capacity of the industry. Naturally this prodigious increase in the number and capacity of plants provided by steelworks has deprived colliery-owned coke ovens of a large proportion of the market for furnace coke. Nevertheless, there is no cessation of coking at the collieries, as is apparent from the fact that, during the period 1934–37, 664 coke ovens were ordered by British collieries. So far as future developments of the industry are concerned, much depends upon the attitude adopted by coal owners and on the education of popular opinion towards a correct understanding of the principles involved. Carbonized fuel, whether solid or gaseous, is eminently suitable for domestic heating. The coal trade must be brought to realize this and steps should be taken to compensate for the inevitable loss of revenue which will follow the disappearance of raw coal from the domestic fuel market. Instead of fighting to retain raw coal in this market by raising the price of coal to those who make smokeless fuel, the coal trade should develop a widespread scheme of collaboration with producers of carbonized fuel. By-product coking is as fundamentally important an industry to the nation as a whole as is the coal industry, and as such it should be developed both technically and commercially with the greatest possible foresight.

A Bridge Without Bolts or Rivets

It is stated in *Electric Welding* of February, a bi-monthly magazine published by the Quasi-Arc Co., Ltd., of London, that the London Passenger Transport Board has placed the contract for the building of a new bridge to carry the Hammersmith and City Railway over Ladbroke Grove, just outside Ladbroke Grove Station. The new bridge is to be of all-welded construction, and will be the first of its type and size in Great Britain. The present bridge has been in service for seventy years. The advantages of having a bridge without bolts and rivets are: the reduction of weight by one fifth, a substantial reduction of cost and much less noise during construction. The new bridge will be 60 ft. long; it will be built on three girders instead of two, and there will be a ballasted track instead of a timber track. These improvements will give much quieter running and also more steadiness and strength. It will be erected on trestles beside the present bridge, and early one Sunday morning the old structure will be rolled away and the new one rolled into place. Dr. Schaper, chief engineer of the German State Railways, stated in a paper last May read before a joint meeting of the Institution of Civil Engineers and the Institution of Structural Engineers that already at that time there were 150 all-welded railway bridges in service on the Reichsbahn up to spans of 177·2 ft. At least as many all-welded bridges have been constructed in connexion with the new German arterial motor roads with spans nearly 100 ft. long. In Belgium nearly fifty welded bridges of the Vierendeel type up to spans of 295 ft. have been constructed over the Albert Canal. It seems certain that, in the future, welding will play an increasingly large part in the technique of construction.

Safeguarding London's Water Supply

Much information of considerable interest to the biologist and hygienist, chemist and bacteriologist is included in the thirty-first annual report of the Metropolitan Water Board, which contains the results of the chemical and bacteriological examinations of London waters during 1936, compiled by the Director of Water Examination, Lieut.-Colonel Harold (London: P. S. King and Son, Ltd. 10*s*. 6*d*.). The daily supply of water in 1936 averaged 287·7 million gallons, yielding 96·5 per cent of samples regarded as being of first-class quality. In the laboratories, 35,075 samples were examined in order to keep a watch upon the purity of the supply. In the Bacteriological Section investigations were conducted on the routine methods for the isolation and identification of *Bacillus coli* and allied bacteria, and on the isolation of *B. paratyphosus* B and of streptococci. Turbidity estimations, and the action on metals of tap-water before and after softening, have been investigated in the Chemical Section. Much trouble is sometimes caused in the reservoirs by the growth of Algæ, and the relation of chemical composition of the water to problems of algal production is one of the subjects investigated in the Biological Section. An interesting find was the blind well shrimp, *Niphargus aquilex*, which is naturally a subterranean species, but which has established itself in the filter beds at the Kempton Park Works. The report concludes with the tables containing the chief analytical results obtained.

Transport of Tropical Fruits and Vegetables

The Imperial College of Tropical Agriculture, Trinidad, publishes, as Memoir No. 7, November 1937, a very valuable summary of the methods now available to bring the produce of the tropics to the English markets, which goes far to explain the greater variety and interest of the window display of the greengrocer and the fruiterer throughout all the months of the year. Some 150 names of vegetables and fruits are listed—for many of these, as citrons, bananas and pineapples there is already much experience gathered and a long bibliography to cite, while others like mangoes and the papaw attract attention as household words of the tropics from which much is to be hoped if distance and time can be conquered; but so far their transport is evidently in the experimental stage. Many of the fruits and vegetables enumerated have been but names, if that, to dwellers in the temperate zones so far; the litchi has arrived in much larger quantities lately and been much appreciated; the mangosteen and the langsat are still awaited. This list raises many hopes, and this concise summary of practical experience should prove of material value in enabling importers and transporters to learn how much has already been achieved and what possibilities there are for the future. Copies of this publication may be obtained (price 4*s*., British; 4*s*. 6*d*., foreign) on application to the Editor, *Tropical Agriculture*, Imperial College of Tropical Agriculture, Trinidad, B.W.I.

Marine Biology in Ceylon

The administration report of the Marine Biologist (A. H. Malpas) for the year 1936 (Part 4, Education and Art (G), Ceylon, 1937) states that the Advisory Committee of the Colonial Development Fund has recommended the offer of a grant of Rs. 87,500, from the fund, to meet the cost of the erection and equipment of a fisheries research station and hatchery in accordance with the scheme approved by the Ministry of Local Administration and submitted to the Secretary of State in 1935. Provision of Rs. 175,000 has been included in the Schedule to the Public Works Loan Ordinance to meet the cost of erection and equipment of an aquarium to complete the scheme. The aquarium is a necessary adjunct to the research station in that its large aquaria tanks will provide essential facilities for investigation and research into the bionomics of food fishes and other marine and freshwater animals of economic importance. Besides this it is proposed to establish fish culture ponds within easy reach of Colombo and to purchase a demonstration fishing vessel—a Yorkshire motor coble with auxiliary sail. The department's research vessel *Nautilus* is to be replaced by a somewhat smaller teak-built vessel with diesel engine, which will be equipped with various types of modern fishing gear and essential research apparatus. This, in conjunction with the coble, will undertake a comprehensive scheme of fisheries research in the coastal waters.

Electron Optics

In the issue of the *Revue générale des Sciences* of February 28, M. R. Fritz, of the University of Besançon, gives a short review of the progress made in the first ten years of its existence of this new branch of optics, which he also denominates electron physics. He starts from the fact that electrons radiating from a point may by means of a uniform magnetic field be made to pass through a second point on the line of the field on which they originated. The analogy with the action of a converging lens on light leads to the term 'magnetic electron lens'. An 'electric lens' may be constructed from three thin parallel conducting sheets with equal circular holes through them, if the outer sheets are at the same and the middle one at a different potential. With these elements he shows how apparatus has been constructed which reproduces the action of microscopes and spectrographs, and he explains how electron optics has rendered the theory of the action of older apparatus such as valves and Braun tubes clearer, and has specified the functions of parts originally introduced empirically. The newer apparatus dealt with is connected mainly with the utilization of secondary electron radiation in television.

The Rockefeller Foundation

The annual report of the Rockefeller Foundation for 1936 contains a review by the president, Mr. Raymond B. Fosdick, the reports of the secretary and the treasurer, and detailed reports of the work of the divisions. The International Health Division has continued investigations on yellow fever, malaria, tuberculosis and other diseases, and has now included scarlet fever and influenza among its inquiries ; it has also been largely instrumental in the production of an effective method of preventive vaccination against yellow fever. In medicine, attention has been mainly concentrated upon mental and nervous diseases, and the Foundation has supported studies in endocrinology, genetics and physiology, and the application of chemical and physical methods and mathematical analysis to biological problems. In the humanities, appropriations have been made, among others, for the development of radio programmes of cultural and educational value, and for education in China. Fellowships to the number of 504, spread over a wide field of knowledge, have been directly financed by the Foundation, and much aid has been given to exiled German scholars.

Land Utilization in Tasmania

As an example of the application of scientific assessment of a country's resources, the survey of the "Land Utilization Regions of Tasmania" by Mr. A. G. Lowndes and Mr. W. H. Maze is important (University of Sydney Publications in Geography, 1937. Price 2*s.* 6*d.*). The authors recognize seven qualities of land values, some of them with subdivisions. These were determined during the summer of 1935–36, and the resultant map may be regarded as an agricultural census of that year with indications of the areas in which further development is possible. The survey shows that climate and topography sets definite limits to possible utilization. The whole of the west and south, with a few local exceptions in the interests of mining, is mountainous and undeveloped and offers little scope for settlement ; some is deforested and has lost its topsoil. On the other hand, the north and east afford great scope for settlement, especially as regards dairying, grazing and horticulture. A number of distributional maps add to the value of the survey.

American Literature on Social and Political Affairs

A further list of inexpensive pamphlets on social, economic, political and international affairs, revised to February 1937, has been issued by the Office of Education, U.S. Department of the Interior, under the title "Public Affairs Pamphlets" (*Bulletin* No. 3, 1937). The compilation, which is limited to material published in the United States, was prepared primarily to meet the needs of the ten public forum demonstrations organizing programmes of public discussion. It is based on information supplied by publishers and is limited to brief pamphlets costing not more than 50 cents. No attempt is made to evaluate the contents of the pamphlets listed, although a brief statement of the contents is given in amplification of the title. Although not a comprehensive list, the indexing and arrangement of this publication according to publishers and authors as well as by subjects, make it a very useful guide to this type of literature.

American School Buildings

SCHOOL building problems in the United States have assumed such importance that a National Advisory Council has been organized under the auspices of the Office of Education, Washington, at the request of State superintendents and commissioners of education. At the Council's first conference it was determined to begin with a study of the "functional planning of elementary school buildings", and a report on this subject has been published by the United States Government Printing Office (pp. 84, 25 cents). The report, which is illustrated with numerous photographs, floor plans and charts, shows, among other things, that the elementary school curriculum is changing in ways which radically affect the planning of buildings, and that costs depend largely on the extent to which school work is organized so as to get a simultaneous, balanced use of all facilities. Taxpayers often protest against the excessive cost of providing for the numerous additions to the traditional "three Rs" demanded by the modern elementary school curriculum: music, art, science, crafts, training for leisure, physical culture, play, etc. The report claims that, by the adoption of the so-called 'platoon' system, accommodation for all these activities can be provided without extra cost. Under this system, the classes are all duplicated, and while one set occupies the 'home rooms' the other set uses the rooms set apart for special activities, and vice versa.

Reading Administratively

A GENERAL administration course of reading has been drawn up by Mr. W. R. Dunlop, 57 Gordon Square, London, W.C.1., designed to introduce the idea of reading administratively. While the course is intended primarily for those holding administrative positions, it has a cultural value and aims at serving as a practical form of education for citizenship, including membership, not only of a country or nation but also of businesses, services and institutions. It is intended to provide standards for criticism, imitation and inspiration. Utilizing material of administrative interest to be found in general as well as specialized works and including fiction and poetry, the course should give a general insight into how man governs in different fields and at different levels in the complex hierarchies of administrative control. While there is no time limit it is suggested that, reading eight hours a week, the recommended literature could be studied adequately in six to nine months, after which the practical reader will begin to specialize. Tuitional assistance is given by post in the form of instruction regarding the meaning and principles of administration and what to look for, more detailed treatment of examples, criticism of readers' notes and the like.

Aquarist and Pond-keeper

WE are glad to note that the *Aquarist and Pond-keeper* is to be published monthly in future instead of every two months. Ever since it was founded by the late Mr. A. E. Hodge, amateur aquarists have had cause to be grateful for its helpful articles on the many aspects of their hobby. These articles have, on the whole, reached a high standard without being too technical. The illustrations, too, have generally been good, some of the photographs of living fishes taken by Mr. W. S. Pitt, for example, deserving special mention. There have, in addition, been regular articles on reptiles and amphibians and their management in vivaria; these must have had considerable effect in popularizing the keeping of such creatures as pets. A section giving notes and news from the big public aquaria is a welcome feature newly introduced. We wish the *Aquarist and Pond-keeper* a long and useful life as a monthly publication.

Campaign against Cancer in Algeria

THE recent establishment of an anti-cancer organization in Algeria is of interest, in view of the particular conditions of race, custom, and climate existing in that country. Already at Algiers, attached to the surgical clinic of the hospital, a centre for treatment and investigation of cancer is in existence, with radiological equipment including a 300 kv. radiotherapeutic installation, and with the necessary laboratory services for cancer research. It is also proposed to install a larger quantity of radium for teletherapy, to set up secondary centres in the country, and to launch a scheme of propaganda against cancer.

Teaching of Technical Optics

IN the article under this title in NATURE of April 9, p. 654, in the reference made to the examinations held by the British Optical Association and the Spectacle Makers Company and to the schools recognized by the former body, it was stated that, outside London and Manchester, the attendance is "of the order of a dozen students in the session". The Principal of the Bradford Technical College writes to point out that the number of evening students taking the technical optics course at the College has in the last eight years averaged upwards of forty students, and that fifteen students have attended the full-time day course in the last five years.

Co-operation between Great Britain and France

A CORRESPONDENT, referring to principles of comity amongst nations, writes: "René A. F. de Réaumur (1683-1757), the French physicist, was elected a fellow of the Royal Society in 1738, during the presidency of Sir Hans Sloane. Later, on May 4, 1745, Réaumur, writing to Martin Folkes, then president, said: 'I heartily wish there was in the world as strong a moral attractive power as there is a natural one that might dispose our two nations particularly to seek to unite by mutual acts of friendship and goodwill.' "

Agricultural Scholarships

THE Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland invite applications for agricultural scholarships from students who propose to follow the career of agricultural organizer or instructor or lecturer in agriculture (including horticulture, dairying and poultry-husbandry). The object of the scholarships, of which not more than four will be awarded annually, is to broaden the agricultural knowledge and experience of students and so to qualify them for the position of agricultural organizer, instructor or lecturer. The value of the scholarships will not exceed £200 together with an allowance for approved fees and travelling expenses. The period of the scholarships is normally one year and commences on October 1. Further information can be obtained from the Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1.

Announcements

The U.S. National Academy of Sciences, Washington, has awarded the Agassiz Medal for Oceanography to Dr. E. J. Allen, who was for forty-two years director of the Plymouth Laboratory of the Marine Biological Association. The Murray Fund, which was established for the award of the medal, was founded by Sir John Murray in 1911 to commemorate the oceanographical work of Alexander Agassiz. The medal was received on behalf of Dr. Allen by Mr. L. McCormick-Goodheart of the British Embassy at Washington, at a dinner held by the Academy on April 26.

The Earl of Radnor has been appointed chairman of the Committee of Management of the Rothamsted Experimental Station. This appointment is in accordance with the long-established usage at Rothamsted of choosing a chairman from among those who are intimately associated with the land; previous chairmen have included such well-known agriculturists as Lord Clinton, Sir Merrik Burrell, Lord Bledisloe and others. Lord Radnor's active interest in rural development and his wide knowledge of the many intricate problems of modern agriculture will undoubtedly prove of great value to the Station.

The Medical Research Council has appointed Dr. Karl Stern to the Kathleen Schlesinger research fellowship for the year 1938–39. This fellowship is provided from a fund established by the late Mr. Eugen M. Schlesinger and Mrs. Schlesinger in memory of their daughter: it is given for investigations of cysts of the brain or allied conditions, and is ordinarily tenable at the National Hospital for Diseases of the Nervous System, Queen Square, London.

The annual visitation of the Fuel Research Station, East Greenwich, will be held on Tuesday, May 31 at 2–6 p.m.

A course of thirty lectures on genetics and cytology and on related studies in pomology and plant biochemistry, for research and post-graduate students and university teachers, will be given at the John Innes Horticultural Institution, Mostyn Road, Merton, London, S.W.19, on July 11–23. Inquiries should be addressed to the Registrar at the Institution.

The next award of the Swiney Prize, which is decided by a joint committee of the Society of Arts and the Royal College of Physicians, will be made in January 1939. The prize, consisting of a cup and the sum of £100, is offered alternately for the best published work on medical and general jurisprudence, and this time is offered for medical jurisprudence. Applications should be made to the Secretary, Royal Society of Arts, John Street, W.C.2, before November 30.

Prof. Hermann Stieve has been nominated president of the International Committee for the Improvement and Unification of Anatomical Terms.

Prof. Martin Kirschner, director of the surgical clinic at Heidelberg, has been nominated a member of the Kaiser Leopold Caroline German Academy of Natural Sciences at Halle.

Dr. Alexander Koenig, professor of ornithology at Bonn, has been awarded the shield of nobility of the German Reich, and Dr. Gottlieb Linck, professor of mineralogy and geology at Jena, has received the Goethe Medal for art and science.

The foundation of a Ministry of Health in Japan has been indefinitely postponed owing to the war with China.

The third Frankfort Conference for Collaboration between Medicine and Natural Science, organized by Profs. R. Otis, K. Felix and F. Laibach, will be held at Frankfort on June 2–3, when the subject for discussion will be the chemistry and physiology of albumin. Further information can be obtained from Universitäts-Institut, Weyerstrasse 3, Frankfurt-a.-M.

The first Pan-American Congress of Endocrinology, which is also the first congress on this subject to be held, will take place at Rio de Janeiro on July 17–23 under the presidency of Prof. Aloysio de Castro. There will be four sections devoted respectively to the experimental, clinical, surgical and medico-social aspects of endocrinology. Further information can be obtained from Academia Nacional de Medicina, Avenida Augusto Severo 4, Rio de Janeiro, Brazil.

The seventh International Congress of Genetics will be held in Edinburgh in 1939 under the presidency of Prof. N. I. Vavilov, vice-president of the Lenin Academy of Agricultural Science and director of the Institute of Plant Industry, Leningrad, and of the Institute of Genetics of the U.S.S.R. Academy of Sciences. The dates of the Congress will probably be August 23–30. Further information can be obtained from Prof. F. A. E. Crew, Institute of Animal Genetics, West Mains Road, Edinburgh, 9.

Cytochrome *a* and Cytochrome Oxidase

A HEART muscle preparation obtained by a method previously described[1] contains several dehydrogenases, a very powerful cytochrome oxidase and the three components (*a*, *b*, and *c*) of cytochrome. This material contains a high concentration of cytochrome *a* and is therefore very suitable for the study of this component.

Spectroscopic examination of this preparation shows only a very diffuse absorption with two or three narrow and scarcely perceptible bands. Neither the removal of oxygen by boiling the preparation in a vacuum nor the addition of potassium cyanide affects this absorption spectrum. Cytochrome remains in the oxidized state, which shows that the preparation is completely devoid of reducing substances and metabolites.

On addition of sodium hyposulphite, the absorption spectrum of reduced cytochrome rapidly appears; showing an exceptionally strong band *a* occupying its usual position at about 605 mμ. Succinic acid added to the preparation also reduces cytochrome, but not so completely as does sodium hyposulphite.

On passing carbon monoxide through the reduced preparation, the bands *b* and *c* remain unmodified, while the band *a* undergoes a very marked change. The short-wave portion of this band becomes pale and spreads towards the band *b*, partly obliterating the clear space between these two bands. This pale portion of the band *a* shows, moreover, a slight reinforcement at about 593 mμ. It looks as if a portion of component *a* combines with carbon monoxide forming a derivative which has its absorption band less defined than the original band *a* and lying at about 593 mμ.

The addition of potassium cyanide to a preparation containing sodium succinate does not affect the absorption spectrum of the reduced cytochrome. On shaking such a preparation with air, only a small portion of cytochrome *a* undergoes oxidation, which is indicated by the band *a* becoming slightly narrower. If, however, this preparation is now treated with carbon monoxide, the carbon monoxide compound does not appear and the band *a* remains unchanged. Only after long standing does the band *a* undergo a characteristic modification due to the appearance of the carbon monoxide compound.

This experiment seems to show that potassium cyanide combines with the trivalent iron of the hæmatin, which inhibits to some extent its reduction by the succinic system and the formation of a compound with carbon monoxide.

On the other hand, if potassium cyanide is added to the preparation when its cytochrome is completely reduced by sodium hyposulphite, the band *a* undergoes a change somewhat similar to that obtained with carbon monoxide, which indicates that the cyanide combines also with the divalent iron of this hæmatin.

Sodium azide added to the reduced preparation does not affect its absorption spectrum. Azide does not prevent the formation of the carbon monoxide compound, which is, however, somewhat delayed owing to the slight inhibitory action of azide on the reduction of all the components of cytochrome by the succinic system.

The effect of carbon monoxide on the absorption band of cytochrome *a* is shown not only by heart muscle preparations but also by preparations obtained from skeletal muscles of mammals, pectoral muscles of the pigeon, fresh thoracic muscles of bees and wasps, and suspensions of living *Bacillus subtilis* or of baker's yeast. In the last two cases, however, owing to the lower intensity of the band *a*, the effect of carbon monoxide, although quite definite, is less marked than in muscle preparations.

All these observations seem to show that the band *a* of cytochrome belongs to two slightly different hæmochromogen compounds having the same hæm nucleus. One of these compounds (a) is not autoxidizable and does not combine with potassium cyanide or carbon monoxide, while the other (a_3) is autoxidizable and combines with both. In this respect it resembles the components a_1 and a_2 which occur only when component a is missing[2].

The carbon monoxide compound of this component has its absorption band at 593 mμ, that is, in the position occupied by the band in the photochemical absorption spectrum obtained by Warburg and his co-workers.

That this compound may be responsible for the photochemical absorption spectrum is, moreover, supported by the fact that the carbon monoxide inhibition of respiration is found to be light sensitive only in the organisms showing the presence of cytochrome a (605 mμ) or of its derivative a_1 (583 mμ).

At first sight, these results seem to suggest that the autoxidizable component (a_3) of cytochrome a is cytochrome oxidase itself. Several facts, however, militate against this view, namely: (1) the existence of cytochrome oxidase in cells devoid of cytochrome a, (2) the oxidation of the three components of cytochrome in air, while the component a_3 remains still combined with carbon monoxide, and (3) the oxidation of the carbon monoxide derivative of this component in presence of sodium azide while the other components remain reduced.

The component a_3, although it may be responsible for the photochemical absorption spectrum, cannot therefore be identified with the oxidase, and the problem as to the nature of this enzyme remains open for further investigation.

The fact that the enzyme is so intimately bound to the insoluble material of the cell makes it extremely difficult to study this problem by the ordinary methods of purification and isolation. In the circumstances, every possibility should be carefully examined and tested by suitable experimental methods, and of these possibilities the following three deserve special consideration :

(1) The enzyme may yet be a hæmatin-protein compound similar to cytochrome *a*, or even a protein sharing with cytochrome *a* its hæmatin nucleus. Owing, however, to its possible low concentration, it may still be spectroscopically invisible even in our strong enzyme preparations.

(2) The enzyme may be an iron-protein compound devoid of porphyrin and resembling some other iron-protein compounds known to occur in tissues.

(3) The enzyme may be a copper-protein compound. Although there is no direct evidence yet in favour of this supposition, it is nevertheless strongly supported by the following considerations :

(*a*) Copper salts are so far the only known simple metal salts which rapidly oxidize all the components of cytochrome. (*b*) The addition of copper to nutrient media for yeast and to copper deficient diet for rats produces not only an increase in the concentration of cytochrome *a* in the cells of these organisms but also greatly intensifies their indophenol reaction[3,4,5]. (*c*) There is a rough parallelism between the intensity of the indophenol reaction of various tissue preparations measured in terms of Q_{O_2} (at 39° C. and *p*H 7·3 in presence of excess of cytochrome *c* and of *p*-phenylenediamine) and their copper contents. (*d*) The only other known intra-cellular enzyme which has many properties in common with cytochrome oxidase is the polyphenol oxidase of plants. This enzyme, as was recently demonstrated[6,7], is a copper-protein compound. (*e*) Moreover, the inhibition by carbon monoxide of cytochrome oxidase in cells devoid of cytochrome *a* resembles that of polyphenol oxidase in being insensitive to light.

Preparation of Radio-Element $^{32}_{15}$P in Weighable Quantity by Means of an Electric Field

In order to obtain large quantities of radiophosphorus for certain experiments, we have attempted to find a method of concentrating the radio-element by means of an electric field. Some attempts of this kind have already been made with success by J. W. J. Fay and F. A. Paneth on bromine, iodine and arsenic[1].

The radiophosphorus was produced by the neutrons from a source of 120 mgm. of radium + beryllium. Very pure carbon disulphide, prepared by shaking for two days with corrosive sublimate and distillation, was placed in a tall glass flask of about 1 litre capacity ; two brass rods with two rectangular brass electrodes soldered at their extremities pass through the stopper ; the field applied was of 70 volts per cm. After nine days of irradiation we examined the electrodes with a Geiger-Müller counter and we measured, on the four faces of the electrodes, the following activities :

anode		cathode	
inside	outside	inside	outside
827	367	427	191

that is, a total of 1,800 kicks per minute. These figures show that the activity of the anode was about double that of the cathode.

The carbon disulphide was submitted to the chemical concentration described by O. Chievitz and G. Hevesy[2]. The result showed that during this first attempt a large part of the radiophosphorus escaped concentration. In order to be sure that this was really $^{32}_{15}$P, we followed the activity of the electrode and the resulting products of chemical concentration for 50 days, and we observed that the activities decreased with a period of 14–15 days, which is that of $^{32}_{15}$P.

Cleaning the electrode with emery paper removes all its activity but boiling it in distillated water does not affect its activity ; though this latter entirely disappears if one puts the electrode in dilute nitric acid for one minute ; in this case, practically all the activity is found again in the residue after evaporation of the acid.

The appearance of the electrodes after irradiation was totally changed, for they were darkened. Experiments done under the same conditions as above, but without neutrons, left the electrodes unaffected in appearance. From this we can conclude that the visible deposit is due to radiophosphorus. It is very probable that the $^{32}_{15}$P formed was combined with the copper or another element of the brass and formed a phosphide of this element.

When repeating the experiment but dissolving a little yellow phosphorus in carbon disulphide and without any irradiation we obtained the same alteration of the brass. In other attempts similar to these, we used pure copper electrodes ; we observed that the copper was altered and covered with a black layer. A qualitative chemical analysis showed that this layer contained phosphorus and copper : so there is very probably formation of phosphide of copper. This determined us to use pure copper electrodes in the following experiments.

These second attempts were conducted in a similar way. The irradiation lasted nine days ; the field was 70 volts per cm. during the first days and 90 volts per cm. during the last three. The electrodes were covered with a black deposit, and the anode alone showed an activity of 1,800 kicks per minute. The electrode weighed before and after the irradiation showed an increase of 3·7 mgm. The remaining carbon disulphide submitted to the chemical concentration had an activity so insignificant that we may conclude that practically all the activity has been collected on the electrodes.

Elimination of the Mosaic Crystal Imperfection Effect on the Width of X-Lines

ON the basis of results obtained by means of different spectroscopic methods, I wish to show that the highest attainable resolving power does not always correspond to the perfection of the crystal measured by means of the double-crystal spectrometer. High resolving power can be attained both with imperfect (mosaic) crystals and with perfect ones.

For example, in the case of crystals of sodium chloride, for the reflecting width w_c the minimum value of 87″ has been found experimentally[1]. According to this value, the width W of the copper $K\alpha_1$ line should correspond at least to 88″ (if the validity of the Gauss equation[2], $W = \sqrt{w_c^2 + D^2 w_\lambda^2}$, is assumed). According to Hoyt's equation[3], $W = w_c + Dw_\lambda$, the value of W for the copper $K\alpha_1$ line should amount to at least 102″. It will be shown here that these relations cannot be used generally.

With Prof. Dolejšek[4], I have obtained by means of the symmetrical spectrographic arrangement, in which the distance slit to crystal equals the distance crystal to photographic plate, with a crystal of sodium chloride an uncorrected value of $W = 15''$ for the true width of the copper $K\alpha_1$ line measured at half maximum of the rocking curve, which corresponds to 0·41 X.U. A similar result was obtained with the lines of molybdenum, where $W = 11''$, that is, 0·30 X.U.

This indicates that the imperfection of the sodium chloride crystals cannot in this case have any influence on the width of the lines as given by the equations referred to above. It is further evident that the values of the width of the lines obtained by us correspond to the true width of the lines of the above-mentioned elements determined by means of the double-crystal spectrometer.

These facts can be explained if two kinds of imperfection of the crystal are assumed. The first kind of imperfection is caused by the mosaic structure of the crystal, which will be designated by $\Delta\sigma$; the second one consists in an irregular arrangement of the atomic planes in the crystal, $\Delta\delta$, or in some other factors. However, it can be shown (unpublished work) when using the symmetrical spectrographic arrangement that reflection on mosaic crystals leads to an angular broadening of the line towards the short wave-lengths:

$$w_\sigma = (\Delta\sigma)^2 \cot \varphi,$$

where φ is the angle of the deflection. The broadening of the lines calculated by means of the formula given above, which holds for the crystal of sodium chloride, can be neglected for X-rays of medium wave-length. When, however, the photographic plate is shifted in the direction towards or from the crystal, so that the distances slit to crystal and crystal to photographic plate are made unequal, a broadening of the line due to the mosaic structure of the crystal is produced. From such a broadening of the line at different distances of the plate from the crystal, the value of w_c for the crystal of sodium chloride was determined, which gave a value of about 100″. If this value is substituted in the above formula, the angular broadening of the lines w_σ is 0·2″ (which corresponds to about 2 per cent of the true width of the lines copper $K\alpha_1$) at half maximum of the rocking curve. This broadening of the line $\Delta\lambda_\sigma = 0{\cdot}008$ X.U. lies below the limit of accuracy attainable by the most accurate methods.

It is thus obvious that crystals with imperfect mosaic structure allow us to get the extreme resolving power when the symmetrical arrangement is used, since the broadening of the lines due to the mosaic structure is negligible.

The second kind of imperfection of the crystal (which cannot be eliminated by means of the symmetrical arrangement) is, as can be seen from our results given above, inappreciable. These facts are in agreement with the findings of Ewald and Renninger[5], which have shown that the small planes of the crystal of sodium chlorine reflect according to the perfect structure, but not according to the mosaic. Thus the influence of $\Delta\sigma$ is approximately the same as in the case of perfect crystals, that is, in the absence of the mosaic structure. According to these results, new methods for measurements of the imperfection of crystals can be worked out; further, the equation for the physical resolving power of crystals, as given by Allison[6],

$$\frac{\lambda}{\Delta\lambda} = \frac{\tan\varphi,}{w_c}$$

must be modified, putting in instead of w_c the function of w_σ and w_δ.

Formation of Negative Ions at Surfaces

ARNOT has described experiments[1] which he has interpreted as showing that a positive ion striking a surface can be converted into a negative ion by capture of two electrons. The negative ions drawn off may have energies in excess of that imparted to them in the accelerating electric fields. Some of this work was not in agreement with other results which one of us had obtained for negative ions, and we have therefore repeated and extended it.

Using an apparatus somewhat similar to Arnot's, but constructed entirely in a blown pyrex tube which could be degassed at high temperature, we were unable to find the negative ion of mercury once the apparatus was thoroughly clean, although initially, whilst a certain amount of impurity was present, a negative ion with approximately the mass of the Hg− ion was found, in agreement with earlier work by Stille[2]. However, bombardment of metal surfaces in the ionization chamber, by presumably mainly Hg+, did produce several light negative ions ($C_2H_2^-$, CO−, etc.), and these possessed excess energy. Subsidiary experiments indicated that this energy did not come from electrical oscillations within the tube; in particular, negative ions with excess energy could be drawn off normally from a flat plate bombarded normally with the positive ions.

These new experiments raised the question of the uniqueness of the mechanism of negative ion formation proposed by Arnot; they seemed rather to support the idea that a major cause of the production of negative ions might be sputtering of persistently occluded electronegative films by bombardment with positive ions. We have now been able to show that the latter process does occur, by using a double mass-spectrograph.

Positive ions were drawn from a mercury discharge, and after magnetic sorting were projected on to a nickel-chrome disk. Negative ions again appeared and were identified by a second magnetic analysis. It was found that Hg^+ and Hg^{++} both produced a spectrum of light negative ions, with maximum peak currents of the order of 10^{-11} amp. Again Hg^- was not detected, although the Compton electrometer used could have measured currents of the order of 10^{-16} amp. A complex positive ion beam of mass about 28 (presumably mainly CO^+) also gave a negative ion beam of about the same mass. In all cases the yield of negative ions was proportional to the bombarding positive ion current. The light negative ions of mass about 28 produced by bombardment with Hg^+ were found again to have excess energies; the other beams have not yet been studied in this way.

The fact that we did not obtain Hg^- is not necessarily incompatible with Arnot's observation of it. We cannot exclude the possibility that differences in surface structure may be responsible for the discrepancy. A question of greater moment is whether in fact any process other than sputtering occurs.

Experiments similar to ours, except that magnetic sorting of the positive ions was not employed, were apparently done by J. S. Thompson[3] in 1931, but, so far as we know, details of this work have never been published.

Response of Barrier-Layer Cells to X-Rays of Long Wave-Length

In 1931 Selenyi and Lange[1] reported that they had obtained photo-currents from barrier-layer cells exposed to X-rays of short wave-length. Later, Gleason[2] studied the effect of X-rays on a large number of cells, and Scharf and Weinbaum[3] made a thorough investigation on this subject.

However, these investigations were all made with hard X-rays; nothing has so far been known of the response of barrier-layer cells to X-rays of long wave-length. I therefore undertook to study this question. Naturally, in this wave-length region such an investigation has to be carried out in a vacuum, and a special apparatus was built for this purpose. The intensity of the radiation falling on the barrier-layer cell could be varied by changing the distance between the focus and the cell. Visible light was completely screened off by two aluminium foils, each of them 0·5 μ thick. For the preliminary investigations two commercial selenium cells of different origin were used. Both these cells had a protective foil of celluloid. This foil together with the two aluminium foils brought the long wave-length boundary of the effective radiation somewhat below 20 A. The short wave-length boundary was given by the voltage of the X-ray tube.

The data in the accompanying table may give a conception of the sensitivity of the cells in this wave-length region. A rough calculation gave the order of magnitude of the photo-electromotive forces to 10^{-4} volt. It has to be observed that in the first case the radiation contained the whole *M*-series of tungsten, and in the second that part of it which contains the strongest lines, but in the last case none of it was present.

Current through the X-ray tube	Distance focus—cell	Short wave-length boundary of radiation	Photo-current
30 m. amp.	15 cm.	3·5 A.	0 86 μ amp.
50	15	5·5	0 66
150	15	8·0	0·62

Further, below 0·9 μ amp., the photo-current was found to be a rectilinear function of the intensity, when the outer resistance was 100, 300 and 1,100 ohms, thus giving a complete resemblance to the conditions in the case of visible light.

Full particulars of the experimental arrangements and further results will be published later.

Composition of Minima in Binary Systems of the Solid Solution Type

In about twelve of the completely isomorphous binary systems which so far have been investigated, the freezing-point curve passes through a minimum. The compositions of these minima are expressed as chemical formulæ in the accompanying table. This table makes clear the remarkable fact that a simple integral relationship exists between the numbers of the atoms of the two metals in the alloy of lowest freezing-point.

System	Composition of minimum point
Au—Cu	Au_3Cu_2
Au—Ni	Au_3Ni_2
Rb—Cs	RbCs
Rb—K	Rb_2K
Pd—Fe	PdFe (?)
Pd—Co	PdCo
Pd—Ni	Pd_9Ni_{11}*
Pt—Co	$PtCo_3$ (?)
Fe—Ni	$FeNi_2$
Fe—Cr	Fe_3Cr
Fe—V	Fe_2V
Sb—As	Sb_4As

* Perhaps more exact experiment may give PdNi, analogous to PdFe and PdCo.

According to Stockdale[1,2], there is a similar relationship between the components of a binary eutectic mixture. However, perhaps owing to some unknown factor, the relationship is not always one of simple integers in this case, but somewhat complex numbers are sometimes given. The law of simple integral ratios seems to be particularly applicable to binary systems of the solid solution type. A system of this type in which the liquidus curve passes through a minimum may be considered as intermediate between the more familiar continuous solid solution system of the gold-silver type and a typical eutectiferous system such as the copper-silver system.

Therefore it is to be expected that as the composition at the minimum of a solid solution system can be expressed by a simple integral ratio, so also can the eutectic composition in a simple eutectiferous system be so expressed. Thus the eutectic compositions of the systems copper-silver and rubidium-sodium, simple eutectiferous systems, can be written Cu_2Ag_3 and the $NaRb_3$ respectively, while the compositions at the minima in the copper-gold and potassium-rubidium systems can be written Cu_2Au_3 and KRb_2.

Relation of Strength of Wood to Shrinkage

The swelling and shrinkage or 'working' of wood under varying atmospheric humidity is an important property of the material, and at most laboratories devoted to the study of wood the measurement of shrinkage is made as a matter of routine on all species. With the view of gaining a further insight into the shrinkage process, measurements have been made here on the shrinkage of very small samples of sitka spruce under conditions where changes in vapour pressure and moisture content could be measured simultaneously with the resulting shrinkage.

These experiments have shown that the volumetric shrinkage S could be connected with the Katz swelling pressure P by a simple relation, $S = aP^k$, where a and k are constants. The equation holds between the waterlogged state (approximately 250 per cent moisture content for sitka spruce) and about 20 per cent moisture content, corresponding to vapour pressures between saturation and about 75 per cent. This range comprises those moisture contents at which most of the water is held by capillary forces. At lower moisture contents, where molecular sorption predominates[1], the shrinkage becomes proportionately smaller than is predicted by the equation. The results of these experiments for the first and second desorption cycles of a particular pair of samples of sitka spruce are shown as a broken line in Fig. 1, together with the results obtained by averaging several routine shrinkage determinations of the same wood, shown as a full line. This graph is, in fact, the stress-strain curve for the shrinkage process, and although neither the shrinkage nor the vapour pressure isothermals for the first cycle are reproducible in subsequent cycles[2], it is interesting to note that the stress-strain curves for the two cycles are indistinguishable in Fig. 1, which suggests that the changes in shrinkage and vapour pressure are due to some modification in the capillary structure of the wood rather than in the material of which this structure is composed.

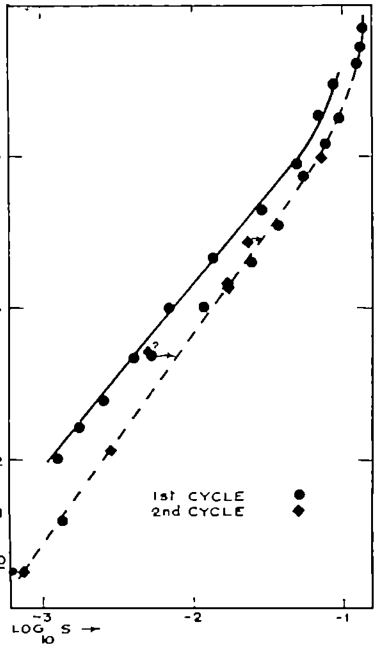

Fig. 1.

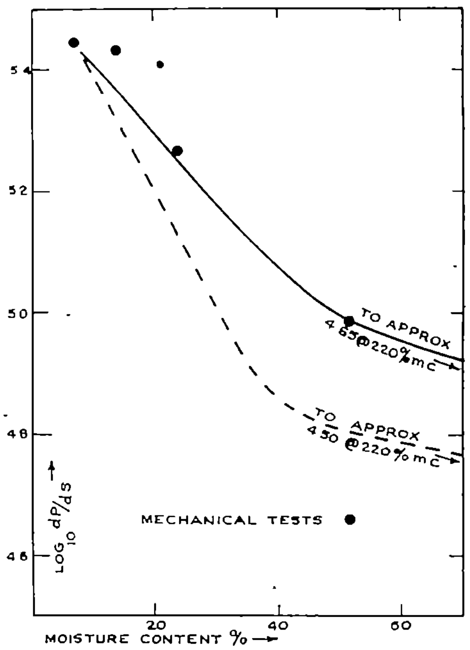

Fig. 2.

Further, dP/dS at any moisture content gives the resistance of the wood to unit hydrostatic compression, which may be compared with dp/ds, that found for external mechanical pressures at the same moisture content. In practice, a uniform hydrostatic pressure cannot be applied to a cellular structure such as wood, so that dp/ds is obtained by calculation from unidirectional pressures and the corresponding Poisson ratios. In Fig. 2 the lines show dP/dS against moisture content for the same material as Fig. 1, while the individual points are average values of dp/ds obtained from mechanical tests on some four or five specimens at each of several moisture contents, p being the stress per unit area of wood-water aggregate. It will be seen that dP/dS resulting from shrinkage forces shows, in the case of the routine tests, a close agreement with *dp/ds* resulting from mechanical pressure, a fact which it is believed has not been previously established. The lower values obtained from the small samples are explicable as being due to chance selection from a very variable material, but it may well be that very small thin specimens would offer proportionately less resistance to shrinkage forces than the larger material used in the routine tests.

It may be further noted that the lines for log dP/dS are straight at moisture contents less than 30 per cent, which agrees with the well-established fact that for most of the strength properties of wood the logarithm of the property increases linearly as the moisture content falls. Owing to the variability of wood, the individual points in Fig. 2, which concern only a small number of samples, would not be expected to demonstrate this relation accurately.

Two Near Extra-galactic Systems

THE reference in NATURE of April 9, p. 636, to the interesting announcement by Shapley of the discovery of another extra-galactic stellar system similar to the two Magellanic Clouds, at probably double their distance, affords another example of the absolute excess of these near systems in the south galactic hemisphere, within a radius of 10^6 light years. Although the position of the centre of the star cluster is not given, it is stated that it lies in the constellation of Sculptor. It must, therefore, lie not far from the south galactic pole, which is included in this constellation, and in the vicinity of the two spiral systems N.G.C. 55 and 300, both of which are of large angular diameter and therefore among the nearer systems to our Galaxy.

Another comparatively near spiral system which has been observed in recent years at Mt. Wilson and Harvard is that of which the nucleus appears in Dreyer's Index Catalogue as I.C. 342. Originally discovered visually about 1889 by the late W. F. Denning in his sweeps for comets, photographs have revealed that I.C. 342 is the centre of a large condensed spiral system, 40′ × 33′, and therefore at a distance only about twice that of the Andromeda nebula and the condensed spiral M. 33. Its position in the northern constellation of Camelopardus places it actually in the north galactic hemisphere, but its galactic co-ordinates, $\lambda = 105°$, $\beta = +11°$, show that it lies unusually near the galactic equator, in fact it is owing to its situation behind the galactic star fields that its real character was not detected before. In this case galactic longitude is more important than galactic latitude, for in reality it is one of the elongated group of comparatively near systems, which includes the Andromeda nebula and N.G.C. 891 on the other side of the galactic equator.

Effect of Acetylene on the Ripening of Kelsey Plums

THE Kelsey plum, a Japanese variety, is at its best a plum of outstandingly high quality, but as grown in South Africa, it is notoriously difficult to ripen after picking, even when gathered at fairly advanced maturity and kept at ordinary atmospheric temperatures.

The capacity for ripening appears to vary from season to season, but a 30 per cent ripening is probably above the normal. In the season just concluded (1938), approximately 9,000 fruits of export standard were kept under observation and only 10 per cent of them have ripened satisfactorily at atmospheric temperatures.

During this season Mr. D. J. Dreyer, senior fruit inspector, and I have made experiments on the effect of acetylene on the ripening capacity of Kelsey plums.

The use of acetylene or ethylene as an agent to accelerate the ripening of fruits is, of course, by no means new; but in the present instance the refusal of the fruit to ripen in ordinary circumstances is so obstinate, and its reaction to gas treatment so striking, that it is of interest to put preliminary details on record.

The typical treatment was to expose the freshly picked Kelsey plums, for 24 hours, at atmospheric temperatures (approximately 70° F.) to an atmosphere containing approximately 1 per cent of acetylene, and then to store them at the same temperatures for ripening. Fruits initially green, or green with a trace of red, were fully ripe within five days after treatment; they were full red in colour, luscious and of good flavour. (The uniformity in ripening is a remarkable feature of the reaction, contrasting as it does with the irregular ripening of usual consignments.) Of the control fruits, only 11 per cent had ripened normally after this period, the remainder being unchanged. By the ninth day, altogether 13 per cent of the control fruits had ripened; by the fifteenth day no more had ripened and the remaining fruits had become shrivelled and rubbery.

Ripening initiated by gas treatment appears to proceed quite normally in so far as acid and sugar changes are concerned. The following figures are typical:

	Total dissolved solids	Malic acid	Ratio of dissolved solids to acid
Unripe fruit	15·2 per cent	0·91 per cent	16·7 : 1
Gas-ripened fruit	14 2	0·15	92 8 : 1
Naturally ripened fruit	16·1	0·14	111·8 : 1

These observations have only been made with fruit picked during the latter part of the Kelsey season, and it is impossible to say whether the earlier fruit would have reacted as vigorously.

A positive result was, however, obtained with fruits which had already been stored at atmospheric temperatures for four weeks, and which had given no indication of ripening. The reaction in this case was much slower than with the freshly picked fruit.

In further experiments it has been shown that unripe Kelsey plums can also be ripened by enclosure for a time in a container with naturally ripened fruits. By the third day there was a noticeable difference between the experimental and the control fruits; and by the fifth day the former were full red, while the latter showed from a trace to one quarter of red colour. By the fourteenth day the control fruits had advanced to about three quarters red.

It appears therefore that, just as in the case of the apple and the banana, an active substance (perhaps ethylene) is produced by ripe Kelsey plums, which is capable of accelerating the ripening process in unripe Kelsey plums. There is, however, reason to believe that relative humidity also plays a part, but critical experiments on these lines have still to be made.

The Polysaccharide produced from Sucrose by *Leuconostoc dextranicum*

THE chemical investigation of the 'dextran' formed when *Leuconostoc dextranicum* is grown on media containing sucrose[1] has given information concerning the structure of the polysaccharide and has revealed facts which have a bearing on the general biological question of enzymatic synthesis.

The purest dextran isolated is a water-soluble and non-reducing white powder with a high positive rotation ($[\alpha]_D^{20^\circ}$ + 180° in water); it appears to be constituted entirely of glucose units. After hydrolysis by boiling normal sulphuric acid, glucose in crystalline form was separated from the hydrolysate in 92 per cent yield.

No difficulty was experienced in methylating the dextran by the usual procedure with methyl sulphate and sodium hydroxide, and fractional precipitation of the methylated product showed it to be essentially homogeneous ($[\alpha]_D$ 210–214° in chloroform; OMe, 44·5 per cent). The methylated dextran is more stable to hydrolytic agents than is methylated starch. Complete hydrolysis of the methylated dextran was achieved by heating with the reagent usually employed in this laboratory for the hydrolysis of methylated cellulose, namely, 50 per cent aqueous acetic acid containing 4 per cent concentrated hydrochloric acid. Separation of the hydrolytic products was effected in the usual way by treatment with methyl alcoholic hydrogen chloride and fractional distillation in a vacuum.

The principal product of hydrolysis was 2 : 3 : 4 trimethyl glucopyranose isolated as the crystalline β-methyl glucoside (m.p. 94–95°; $[\alpha]_D$ − 21° in water). The trimethyl sugar ($[\alpha]_D$ + 68° equilibrium value) gave a crystalline anilide (m.p. 145–6°), was oxidized by bromine water to a δ-lactone ($[\alpha]_D + 80^\circ \rightarrow + 32^\circ$ in 21 hr.) and by nitric acid to 2 : 3 : 4 trimethyl saccharolactone methyl ester (m.p. 106–107° alone or in admixture with an authentic specimen).

The fractions obtained in the vacuum distillation of the glucosides were contaminated with methyl lævulinate (characterized as the phenylhydrazone, m.p. 106°), and it was found advisable to remove this constituent by treatment with barium hydroxide and then to refractionate the glucosides. There were indications, chiefly from the refractive index, of the presence of a small amount of tetramethyl methyl glucoside in the first fraction which, after hydrolysis with aqueous acid, had OMe 46 per cent (a trimethyl sugar requires OMe 41·9 per cent). This was confirmed when the methylated sugars from the hydrolysed first fraction were heated with aniline. The anilide which separated was tetramethyl glucose anilide (found OMe 40·3 per cent; $C_{16}H_{25}O_5N$ requires OMe 40 per cent). After recrystallization from absolute alcohol, the anilide had m.p. 135–6° and there was no depression of melting point in admixture with an anilide prepared by the same method from crystalline tetramethyl glucopyranose.

Full details will be published later, but it would appear from these results that the dextran resembles starch and cellulose in that it is constituted solely of glucose residues united to form a chain molecule. The fact that 2 : 3 : 4 trimethyl glucose is the main product of hydrolysis of methylated dextran establishes the nature of the link between the glucose units as being 1 : 6-glucosidic (the gentiobiose linkage) and the isolation of tetramethyl glucose suggests a terminated chain. The proportion of tetramethyl glucose is estimated to be approximately 0·23 per cent of the weight of methylated dextran, which corresponds to a chain length of 550 glucose units. No finality is attached to this latter figure, especially as an osmotic pressure determination gave 200 units, and the possibility of effecting a quantitative separation of tetramethyl glucose as the anilide is being explored.

The Oxidation-Reduction Potential in Lignifying Cells

DURING the lignification process of the cell walls the carbon content increases considerably. A strong reduction must take place in the living cells which begin to lignify. We have tried to determine the reduction potential of the tissues by means of the colorimetric method applied thus far only to isolated cells (unicellular organisms, and in yeast- and bacteria-suspensions). The results are still of a qualitative character, but they seem significant.

Tissues scraped from the hypocotyledons of the stems of sunflowers by means of a piece of broken glass were used: (1) cortical parenchyma; (2) cambium tissue near the xylem; (3) cambium tissue near the phloem; (4) older wood tissue; and (5) medullary parenchyma. These tissues, after carefully washing off the adherent cell juice, were brought into Thunberg-tubes filled with 8 c.c. of very dilute (0·001–0·005 per cent) solutions of oxidation-reduction indicators (six dyes were used, ranging from rH 18 to rH 8) and 2 c.c. of the Sorensen phosphate buffers ($pH = 7$). After evacuation, the glass tubes were placed in an incubator at 30° C. Tubes filled only with solutions of the dyes for comparison of the colour, and tubes filled with liquid and killed tissues, which do not reduce, served as controls.

The cambium tissue near the xylem reduced most quickly and intensely. In the cortex the reduction was less marked. The medullary parenchyma had a much weaker action, while the activity of the older wood tissue (of course dead for the greater part) was very scanty.

A corroborative result was obtained with transverse sections of the stem. The results were very satisfactory in most cases, notwithstanding the unfavourable period (autumn). They were, however, variable according to the vitality of the plants used. The later in autumn the experiments were carried out the more the reducing power was diminishing. In November the reducing power has become very small but, at all times, the cambium showed the highest activity.

Developmental Forms of the Virus of Lymphogranuloma Inguinale (Climatic Bubo)

IT is now generally agreed that in lesions produced by the virus of lymphogranuloma inguinale (climatic bubo) there can be seen small elementary granules which by staining and by differential filtration appear to be 100–175 mμ in size. These granules almost certainly represent the etiological agent of the disease. In smears from infected mouse brains these granules may occur (1) diffusely scattered outside the cell, in the form of colony-like masses; (2) within the cell cytoplasm, when they may be surrounded by a definite membrane; or (3) closely adherent to ruptured cells. The granules are stained blue by Castaneda's stain, blue with Victoria B, and reddish-violet by Giemsa's method.

In addition to the small forms, though less numerous, we have been able to find, in lesions produced by three strains of the virus, large bodies three to four times the size of the small forms. These large forms are present especially in very early lesions, and are somewhat irregular in shape, often suggesting division by fission: intermediate bodies between the large and small forms also occur. Very occasionally small masses of large forms only are seen occurring in plaques; more commonly collections of small granules are found containing a few large forms.

The evidence at present available suggests that the small granules are derived by division from the large forms. These large forms stain a bluish-violet by Giemsa and a reddish-purple by Castaneda's method. The various forms of the virus of lymphogranuloma inguinale present many analogies to those exhibited by the causal agent of psittacosis.

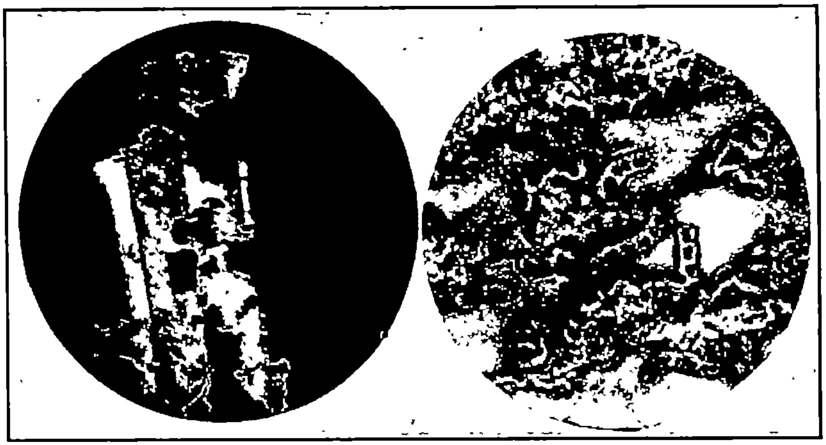
Disintegration of Cell-Wall Substances in the Gastro-Intestinal Tract of Herbivora

THE process of cellulose digestion in herbivora, in addition to its economic importance, throws considerable light on a number of cognate biological topics. Biochemical aspects of the problem have received considerable attention. Pure cultural investigations have been attempted though it is questionable whether the species isolated *in vitro* are those primarily concerned with the process taking place *in vivo*. It is therefore remarkable that so few attempts have been made to study the changes occurring *in situ* by direct microscopical observation. This method has been successfully applied by us to material derived from the cæcum of non-ruminant herbivora.

Disintegration is evidenced by the formation of clearly defined zones of erosion termed *lacunæ*. In the affected regions loss of double refraction corresponds precisely to changes in microchemical and staining reactions. Stages in micellar disorganization are indicated by diminution or loss of dichroic intensification. Pectic substances are dissolved (ruthenium red). Cutin entirely resists attack (Sudan III). Heavily lignified structures are immune. By the use of appropriate reagents and stains, the cytoclastic micro-organism can be demonstrated in the interior of lacunæ.



(*a*) (*b*)

PLANT STRUCTURES FROM CÆCUM OF THE HORSE.

(*a*) Epidermal tissue. Polarized light. Crossed nicols. Localized disappearance of double-refraction in the zones of erosion or lacunæ (black). × 400 approx.

(*b*) Stained Congo-red and iodine. Lacunæ situated in pink substratum which shows dichroic intensification with a single nicol (Ambronn effect). At the edges of the lacunæ the cytoclastic micro-organisms can be seen (blue, with iodine). The staining at the margins of the lacunæ is intensified. × 1,200 approx.

The above methods when applied to material from the cæcum of the guinea pig[2,4], rabbit[3] and horse (in the press) yield strictly comparable results. The cytoclastic micro-organisms include vibrionic, coccoid and giant forms[3,4]. It appears that they are stages in the life-cycle of some polyphasic species. The coccoid and giant forms give a blue (amylodextrin) reaction with iodine. Their shapes correspond with precision to the contours of the excised lacunæ.

These investigations have recently been extended to the stomach of ruminant herbivora. In the sheep, disintegration of the optically birefringent substances of the wall has been demonstrated by the application of the methods outlined. The primary agents are iodophile micro-organisms very similar to those observed in the cæcum of the species mentioned. To the indigenous protozoa of the paunch only a subordinate role can be assigned. The size of the plant fragments originally present is such as absolutely to prohibit ingestion. Smaller fragments are afterwards ingested; but these have in the majority of cases been detached, and in consequence already in part disintegrated, by the activities of the iodophile micro-organisms. Similar considerations hold for the protozoa of the horse. In both instances, however, digestion of starch grains and iodophile micro-organisms has frequently been observed.

Scientific Tests of Telepathy

It is probable that most psychologists and practically all physiologists regard the evidence in support of 'clairvoyance' and 'telepathy' as worthless from a scientific point of view. So naïve, as a rule, are the arguments used by those anxious to give verisimilitude to the results of imposed tests that few scientists are willing to discuss or even seriously to consider these subjects with their question-begging titles. This is regrettable, as the public are apt to draw erroneous conclusions when they see reiterated statements in the popular press pass unchallenged. For this reason Mr. S. G. Soal, senior lecturer in pure mathematics at Queen Mary College, University of London, is to be congratulated on having conducted detailed investigations into certain alleged 'psychometrising' faculties of the medium 'Marion', and for having published in the press[1] and elsewhere[2] his conclusions thereon. It is yet more a subject for congratulation that a periodical of the scientific status of Nature[3] is willing to devote space to reports upon investigations of this subject.

"In spite of all the vast tomes that have been published on psychical research," writes Mr. Soal in the Bulletin (p. 3) to which reference has been made, "I have yet to meet the human being who under similar conditions can do what Marion has failed to do !" This, one of many comments—all adverse to a telepathic interpretation—appended by Mr. Soal to the results of the experiments, both recalls and endorses the following dictum by the late Sir Ray Lankester.

"Telepathy is simply a boldly invented word for a supposed phenomenon which has never been demonstrated. It is an unfair and unwarranted draft on the credit of science which its signatories have not met by the assignment of any experimental proof. There is not one man of science, however mystic and credulous his trend, among those who pass this word 'telepathy' on to the great unsuspecting, newspaper-reading public, who will venture to assert that he can show to me, or to any committee of observers, experimental proof of the existence of the thing to which this portentous name is given."

The late Sir Bryan Donkin, a psychiatrist of considerable repute who had devoted no little attention to the claims of 'thought-readers', used to say of the above quotation that it constituted a masterful summing up of the whole case for telepathy.

Science and the Unobservable

In Prof. Dingle's lucid rejoinder to my letter[1] the difference in our points of view stands out very clearly. It hinges on the meaning of such terms as "denial" and "pronouncement".

I do not think that relativity as a scientific theory "denies" the existence of absolute simultaneity in the dogmatic sense in which Prof. Dingle seems to employ that word; the third horn of the dilemma on which he would impale me thus turns out to be made of sand. Stated explicitly, relativity as a scientific theory makes only such pronouncements as the following concerning absolute simultaneity: (1) at present it is not a significant concept in physics; (2) known facts raise a presumption or expectation that it never will be; (3) if we assume certain postulates or working hypotheses which preclude the existence of absolute simultaneity, such and such conclusions follow. That is all.

Precisely this careful avoidance of *dogmatic* pronouncement seems to me to be of the very essence of the scientific method, and I think it is a mode of approach that is badly needed in attacking many other problems.

E. H. Kennard.

Cornell University.
April 8.

---

[1] Nature, **141**, 557 (March 26, 1938).

I agree with Prof. Kennard's three statements on the pronouncements of relativity, but if, as he truly says, "That is all", what has become of the "world existing independently of experience" which was regarded as essential in his first letter ? Of the three attitudes which I considered incompatible, he has chosen those of the relativist and the non-professor of omniscience, and abandoned that of the realist as defined; he is now entirely in the realm of concepts, known facts, assumptions and rational deductions. In the terms of my former letter, he has shown no reason for giving $A - A' - A''$ a non-zero value. Immediately, therefore, he adds the realist contention that it has such a value, he makes an unfounded statement and so becomes dogmatic.

I would add that I am in complete agreement with Prof. Kennard concerning the undogmatic character of the scientific method, and the need for its more general application. The importance of this matter, particularly in the social, political and religious spheres, is, indeed, one of the chief reasons why I think it is necessary to see science exactly as it is without adding to it a totally irrelevant "independent universe" which fulfils no function but that of making false philosophies plausible.

Herbert Dingle.

Imperial College,
London, S.W.7.

Social Relations of Science

THE Association of Scientific Workers has been mentioned in several of the contributions to the supplement in NATURE of April 23 on the proposed Society for the Study of the Social Relations of Science. On behalf of the A.S.W., I venture to direct the attention of readers to our work during the last ten years in the field which the S.R.S. proposes to cover.

The A.S.W. has a dual policy which includes the study and the improvement of the relations between science and society as well as the promotion of the professional interests of scientific workers. The Association has endeavoured to pursue the first object of its policy by publishing a journal called *The Scientific Worker*, by holding public lectures, and recently, by arranging showings of scientific films. For lack of adequate means we have not been able to satisfy the urgent need for properly organized research into the influence which many aspects of science are now exerting on our social life. Such work could only be done under the auspices of a society such as the S.R.S., and we are glad to notice that, in the contributions to the supplement in NATURE, several of our vice-presidents emphasized this aspect of the future work of the S.R.S. It is also necessary that the general public should be kept more in touch with the actual nature and purpose of scientific education and research.

The potentialities of an S.R.S. seem to us to be very great, and we should both welcome its formation and willingly co-operate in its work.

W. A. WOOSTER.
(Honorary General Secretary.)

Association of Scientific Workers,
Kelvin House,

London, S.W.5.

Points from Foregoing Letters

FROM the behaviour of a special preparation of heart muscle, containing a high concentration of cytochrome *a*, when treated with various reagents, Prof. D. Keilin and Dr. E. F. Hartree deduce that the absorption band *a* of cytochrome belongs to two slightly different compounds, one of which is autoxidizable and combines with potassium cyanide or carbon monoxide, while the other does not possess these properties. They also enumerate reasons for suggesting that the enzyme which oxidizes cytochrome may be a copper-protein compound.

By irradiating carbon disulphide for several days with neutrons in presence of a strong electric field (70–90 volts per cm.), J. Govaerts has been able to concentrate the radiophosphorus produced almost entirely upon the anode, which increased in weight by 3·7 mgm.

There are two kinds of imperfection causing loss of resolving power in the X-ray spectra of crystals, according to J. M. Bačkovský. One is due to mosaic structure and the other to the regular atomic planes. By using a symmetrical spectrographic arrangement for X-ray study in which the distance slit to crystal equals the distance crystal to photographic plate, the author has been able to reduce the broadening of the lines due to mosaic structure and to render its effect negligible.

Dr. R. H. Sloane and R. Press describe some new experiments on the formation of negative ions by the bombardment of metal surfaces with positive ions. These experiments show that positive ions of one species can produce negative ions of another species, and this seems to require a sputtering mechanism for its explanation.

Photo-electric selenium cells are found by Dr. A. E. Sandström to be susceptible to X-rays of long wavelength, somewhat below 20 A. Under suitable conditions the photo-electric current is proportional to the intensity as in the case of ordinary light.

A table is given by M. Hara, showing that in twelve bimetallic alloys with lowest freezing point the metals are in simple atomic ratio, corresponding to that of simple chemical compounds (Au_2Cu_3, $FeNi_2$, etc.).

Graphs showing the relation of swelling pressure to shrinkage in the case of samples of sitka spruce, and also the resistance of the wood to compression at different moisture contents, are submitted by W. W. Barkas and H. Q. Golder.

Successful ripening of the Japanese Kelsey plum grown in South Africa, by treatment of acetylene, is reported by V. A. Putterill.

Chemical investigation of 'dextran', a compound synthesized by the seaweed *Leuconostoc dextranicum*, when grown in a sugar solution, shows that carbohydrate to be similar to starch and cellulose, being constituted solely of glucose residues. There appear to be several hundred glucose units in the dextran molecule.

During the lignification of plant cell-walls, an increase in the carbon content and consequently a reduction process takes place, according to K. Griffioen. Colour tests with oxidation-reduction indicators support this view as they show that the cambium layer near the wood cells has greater reducing power than other cells, particularly during the growth season.

Dr. G. M. Findlay, R. D. Mackenzie and F. O. MacCallum report the presence of Giemsa-stained granules in early lesions of the virus disease, climatic bubo, these being three or four times larger than the previously observed (presumably virus) granules. The authors suggest that the smaller granules are derived from the larger ones by division.

F. Baker and R. Martin demonstrate the disintegration of optically birefringent cellulose and other cell-wall substances in the cæcum of the horse, etc. Loss of double-refraction in the zones of erosion is accompanied by changes in microchemical reaction. Pectins are also attacked. Lignin and cutin appear to be immune. The cytoclastic agents are iodophile micro-organisms, probably stages in the life-cycle of a single polyphasic species. Protozoa, where present, play, if any, only a subordinate part in the process of disintegration.

Research Items

Navaho Ceremonial

IN view of the comparatively limited character of knowledge of the ceremonial complexes of the south-western Indians of the United States, the Department of Anthropology of the University of Chicago has been induced to sponsor a series of studies combining the study of Navaho ceremonialism with an intensive study of the language. The first of the series is the text of "Enemy Way", commonly known to the white population as the war dance, one of the most popular ceremonials ("Origin Legend of the Navaho: Enemy Way". Text and Trans. by Father Berard Haile. *Yale Univ. Pub. in Anthropology*, 17, 1938; Oxford Univ. Press. Price 16*s*. net.) In Enemy Way there are a number of ceremonies, each with a specific ritual function, such as "decorating the rattle-stick", "strewing the ashes", etc., each of which is accompanied by sets of songs. The term 'shaman', as generally understood, is foreign to native conception. Though the 'singers', both men and women, are a distinct class in the tribes, their organization is very loose: they do not form lodges, fraternities or schools, while a singer does not offer his services, but awaits a summons. Their knowledge is not restricted by clan, or heritable. It may be purely mechanical and limited to the reproduction of songs required by a given ritual. The power to function as a singer, however, is transmitted from singer to pupil; and no one, however familiar with the material, would act as singer, unless he had been inducted. Women are not barred, although there are few female singers to-day, and in Enemy Way none, because women are not warriors. The Enemy Way legend, conceived as a whole by the narrator, may for convenience be treated as falling into three parts. Of these, the first deals with the origin of the people from the underworld, and their struggle with the man-devouring monsters, who originated from the sexual misdeeds of the women. This struggle made the earth fit for the present human race, which is identified with the Navaho. The second part of the text describes the war on Taos, in which a number of ritual practices, typical of tribal war, are described. The third gives an account of the Enemy Way ceremonial by which the patient, personifying the earth suffering from these conflicts, is put right.

Function of Golgi Apparatus

IN a further study of the structure of the Golgi apparatus, Dr. M. K. Subramaniam has observed in alimentary canal cells of *Lumbriconereis* two types of secretion (*Proc. Indian Acad. Sci.*, 8, Sect. B, 125, March 1938). In cells producing a watery mucous secretion, the Golgi apparatus consists of granules and vesicles. The secretion vacuoles arose in contact with the chromophilic rim of the Golgi vesicles. In cells producing the granular type of secretion three types of association between the Golgi bodies and the secretory product were observed: granules arose in intimate relation with the idiosome of the Golgi batonettes, developing granules were closely pressed against small Golgi vesicles, and typical Golgi batonettes, double-rimmed batonettes and Golgi vesicles were seen plastered on the surface of a secretory granule. The author is convinced that there is some fundamental plan in the Golgi apparatus common to all cells, whether vertebrate or invertebrate, and that the different patterns in different cells when analysed resolve into variations of a single basic procedure.

Indian Breeds of Cattle

THE study of native breeds of cattle has assumed great importance since it was realized that they possess a power of disease resistance often lacking in imported breeds of European strains, and that united with this quality they often possess a potentiality of improvement under suitable conditions of husbandry. The humped cattle of India are of special importance in such studies on account of their numbers, estimated at 200 million, and of the part they have played in the development of some of the widely diffused breeds of African native cattle. In "A Brief Survey of some of the Important Breeds of Cattle in India", published at the instance of the Imperial Council of Agricultural Research (*Miscellaneous Bulletin* No. 17; 1938), Sir Arthur Olver describes the distribution and outstanding characters of twenty-one breeds of cattle and four breeds of buffaloes, illustrated by 52 plates of photographs. The cattle breeds fall into five basic types, which appear to have been brought to India at different times with waves of immigration from various centres. The descriptions and photographs convey the impression that India possesses great wealth of fine cattle breeds, well worthy of development by selection and research. The possibilities are great, for it has already been shown that, in comparatively few years, selected milch breeds of pure Indian origin can, by scientific feeding and management combined with systematic breeding control, be raised to levels of efficiency as high or higher than those of imported European cattle or their cross-breeds.

Tobacco Leaf-curl in Northern India

DR. B. P. Pal and R. K. Tandon of the Agricultural Research Institute, New Delhi, have presented a first report (*Indian J. Agric. Sci.*, 7, Pt. 3, June 1937) on the investigation undertaken at Pusa on the tobacco disease known as leaf-curl, which is becoming a serious menace in northern India. They identify the disease with that described by Thung in Java under the name of 'kroepoek' and with the leaf-curl of East Africa which Storey studied and showed to be conveyed by a species of white fly. The authors distinguish five different types of disease, four of which they regard as distinct and due to different virus agents, and the fifth as due to a mixture of two or more of the former. Indeed, by grafting scions from two of the distinct types on to a healthy plant, they have reproduced a clinical condition indistinguishable from that regarded as the fifth disease under review. There is evidently a close resemblance between the types of disease found in

India and those observed by Thung in Java. The presence of carriers amongst weeds common to the Indian plantation is suspected,* but no definite evidence of such has been adduced.

Silicon Monoxide

W. Biltz and P. Ehrlich (*Naturwiss.*, 26, 188; 1938) report the interesting fact that on heating a mixture of equimolecular proportions of silicon and silica to 1400° in a vacuum, volatilization occurred to the extent of 80 per cent in an hour. Silicon itself would only volatilize to the extent of 10 per cent under the same conditions, and quartz has no appreciable vapour pressure. A vitreous sublimate, which was brown in thin layers, and brownish-black in thicker deposits, was obtained, and most of it could be resublimed. It seems possible, but not certain, that the product may be silicon monoxide. This substance has, of course, been previously prepared by the reduction of silica with carbon in the electric furnace, and has been used as a pigment, and for other purposes.

Heat Resisting Steels

PROGRESS in the metallurgical industry during recent years has been towards the provision of a number of alloy steels which are capable of withstanding both oxidation effects and high stresses at enhanced temperatures. On March 24, W. H. Hatfield presented a paper to the Institute of Fuel in which he recorded the results of experiments carried out on fourteen different compositions, including mild steel. The purpose of this experimental work was to make a comparison of the properties and characteristics of these steels and at the same time evolve a basis of evaluation of their efficiency for specific purposes. Consideration of the data shows that there are steels available which have a time yield of not less than 3,360 lb. per sq. in. at 700°C., whereas that of mild steel at the same temperature is of the order of 400 lb. This in point of fact means, when translated to everyday requirements, that reasonable permanence of dimensions can be anticipated from certain steels, and reasonable stresses can be borne by them even at a red heat. Further, various ingredients such as nickel and tungsten may be added to increase the strength of steel. It is therefore incumbent upon the engineer before selecting steel to consider carefully the service required of it and also the conditions of service, such as temperature distribution, atmosphere and general physical conditions, so that the right ingredients may be incorporated in the steel in suitable proportions.

A Randomizing Machine

IN certain statistical investigations it is necessary to have a set of random sampling numbers. The only table of such numbers at present in existence is due to L. H. C. Tippett, who compiled it by taking digits at random from census reports. There is some difference of opinion as to whether this method is reliable, but whether it is so or not, there is certainly a need for more extensive tables. To produce these, M. G. Kendall and B. B. Smith have designed a randomizing machine (*J. Roy. Statistical Soc.*, 101, 147; 1938). This consists of a disk divided into ten equal sections, on which the digits 0 to 9 are inscribed. The disk rotates rapidly, in a dark room, at a speed which can be made very approximately constant by means of a tuning fork, and it is illuminated by a series of flashes from a neon lamp. At each flash a number is chosen from the apparently stationary disk by means of a pointer fixed in space. The first five thousand digits obtained in this way are given in the appendix to the paper mentioned above. Four tests for randomness (the 'frequency', 'serial', 'poker' and 'gap' tests) were applied to these numbers, with satisfactory results in each case. Further experiments are needed before it can be established that the results will be equally satisfactory for much more extensive sets of numbers, but the preliminary results are very encouraging.

Observations of Meteor Showers in Japan

SHOWERS of Orionid, Leonid and Geminid meteors were observed last year by Mr. K. Komaki, Mrs. Komaki, and Mr. K. Yosii, at Kanaya and Takehara. The Orionids were not so rich as in the previous year, but the Leonid shower was slightly richer than it has been for some years. Mr. Yosii discovered a new stream, the radiant of which was R.A. 72°, Dec. + 37°. These meteors were white or yellow and their motions were slow. The Geminids were observed on December 6–15, and the frequency was about the same as in previous years, the maximum occurring on the morning of December 14. On December 12 and 13 the radiant was close to R.A. 112°, Dec. + 32°, and on the morning of December 14 Mr. Yosii detected two showers from R.A. 109°, Dec. + 30°, and R.A. 122°, Dec. + 33·5°.

A Variable-Frequency Telescope Drive

THE recent paper by Mr. H. W. Cox under this title (*J. Brit. Astro. Assoc.*, 48, 6; April 1938) will be useful to amateurs who wish to instal an efficient and cheap drive for their telescopes. The mechanism depends upon the principle that in a synchronous type of motor the motor speed is proportional to frequency, and this latter is varied by what is practically a radio set on the bottom end of the telescope. If a coil and a condenser are connected in parallel, they have a natural resonant frequency, and this can be regulated by varying the capacities. Hence it is possible to arrange a resonant frequency of the circuit which will coincide with the operating frequency suitable for any synchronous motor that is desired. The tuned circuit is unable to drive the motor, but by connecting the tuned circuit to an ordinary radio valve, the circuit and valve can be made to oscillate and produce a 50-cycle voltage of 10 or 20 volts, which can be brought up to 200 volts by another ordinary type of radio valve. When the voltage and power have been amplified to the correct amount, connexion to the motor is made through a transformer, just as a loud-speaker is connected to a radio receiver. The frequency is varied, as already mentioned, by altering the condenser or coil, and as the former is made up of a number of small units, each of these smaller condensers being connected independently into the circuit by a switch, the rate of the motor can be regulated. Mr. Cox supplies three diagrams with his paper, and those who are skilful with manipulating wireless sets should be able to fix up the drive for their telescopes, as the diagrams show the method of connexion and also various refinements introduced to produce the most accurate results.

Speech and Civilization

By Sir Richard Paget, Bt.

IT is a very remarkable fact, little known to students of human speech, that uneducated deaf mutes, even to-day, have no inborn knowledge of any sign or symbol equivalent to a word. They naturally symbolize their ideas by a general pantomime describing events as a whole. They have not got the power of analysing their environment into separate categories of objects, actions, qualities, etc., or of symbolizing such separate elements by bodily signs equivalent to our spoken words.

The fact that intelligent human beings, skilful with their hands and capable of craftsmanship, are still in this primitive and unanalytic state of mind—in which they are unable to define anything because they have no units with which to define—seems to indicate that our present powers of analysis and of separate symbolization of the elements out of which our general impressions are composed, may be a comparatively recent acquisition of mankind. It also seems possible that the acquisition of this power may be closely allied to what we call 'civilization'.

Assuming that the development of true speech arose from primitive man's acquisition of the power of analysing his environment (as presented to him by his various senses) and of symbolizing the component parts in units and categories—equivalent to our 'parts of speech'—how did this process begin ?

Perhaps the evidence of primitive man's artistic skill, for example, in his early cave drawing, sculpture and modelling, may give the clue.

Primitive man—keen hunter—skilled in recognizing shapes (cf. Pavlov's dogs)—must have often come across natural flints (which were of special interest as the raw material of his tools and weapons) of peculiar shape, which reminded him of certain animals—birds—or even human beings. Stones with curious holes through them—so that they could be made into 'knob-kerries' by pushing a stick into the hole—or smaller stones which could be threaded on a leather thong or a fibre string, and worn as ornaments, would also be very interesting, and 'magical' to him. It would not be long before man would try his hand at improving such finds, for example, by knocking off excrescences which 'spoilt' the form of a particular piece of natural sculpture.

It would also be natural that man should observe the plastic qualities of clay, and the way it preserved the imprints of animals and birds and of man himself, which appeared on it. As we know, he did make imprints of his hands on the walls of some of his caves.

Beginning thus with sculpture and modelling, it would not be long before man began outlining other objects, just as the imprint of his foot or hand on a soft surface of clay incidentally outlined the shape of the palm, or the sole of the foot.

The new factor in all this was that the artificial animal, bird or human, or the imprint or drawn outline symbolize the creature in question apart from its environment. The object symbolized could be considered by itself, apart from any environment; it could be viewed in any position, at any time, in any place where its owner chose to take it, or wherever he modelled or drew or impressed it.

Primitive man was not limited to the symbolizing of objects ; he could also symbolize actions, such as hunting, dancing and other bodily movements or postures, namely, by drawing crude representations of the actions in question.

The same method of representing actions was later developed by the Red Indians of North America, so that it became a complete script. The Chinese, Sumerians and Egyptians developed a similar technique, which ultimately became formalized as the Chinese ideograph, cuneiform and hieroglyph, respectively.

Thus, it may be that primitive man acquired the art of analysis of impressions, and of the symbolization of separate elements of his impression, from his first observations of natural objects which he recognized as being like other objects !

The moment he began to study natural objects with the view of drawing or modelling them, he had to concentrate his mind on them and, in fact, to isolate them from their environment, for the act of drawing or modelling was in itself a symbolizing of the model, or of the action or quality which he portrayed.

It seems likely enough that this process of symbolizing by drawing or modelling should have been used very early, in magical practice ; indeed, the power of producing stones, clay shapes or drawings, which looked like or suggested living forms, must have appeared highly magical to the tribal contemporaries of the earliest artists. It may well be that the artists were in fact the earliest 'priesthood'.

Turning now to the evolution of speech, the pre-analytic stage of sign language was, obviously, accompanied by an emotional 'gabble', due to the (Darwinian) sympathy of movement between man's hands and mouth. As man acquired the art of symbolizing animals, men, women, bodily actions, relative positions, sizes and other qualities, etc., namely, by drawing symbols of them on a flat surface, he would equally acquire the art of symbolizing these elements by bodily pantomime (including in this the art of outlining in the air) as educated Chinese to-day draw ideographs to be read by a Chinese who speaks a different dialect but uses the same method of ideographic writing. In this way, an analytic form of sign language would naturally grow up ; combined, of course, with general (non-analytic) pantomime. The gabble would thus tend to be gradually combined with particular mouth movements (due to corresponding hand movements) which always meant the same thing—that is, with actual words.

It would be interesting to know whether a study of the speech of the most primitive tribes of mankind gives any evidence of this process—the use of bodily pantomime of a more or less free and unstandardized type (accompanied by an emotional vocal gabble) combined with the use of standardized words for such objects, actions, etc., as would naturally be symbolized in very early stages of human development. It would also be interesting to know whether

Science News a Century Ago

Publication of Newton's "Principia"

AT a meeting of the Ashmolean Society, Oxford, on May 14, 1838, over which Dr. Buckland presided, Prof. S. P. Rigaud (1774–1839) the Savilian professor of astronomy, read a paper on the first edition of the "Principia" of Newton. After referring to Newton's early speculations on gravitation, Prof. Rigaud said that the statement in the "Commercium Epistolicum" that he communicated some of his principal propositions of the "Principia" to the Royal Society, in 1683, was certainly a year too early. The first notice of them was given at the latter end of June 1684, and a more specific specimen of the treatise was probably sent in February 1685. The commonly received opinion was that the Royal Society was at the expense of publishing the "Principia" but this was decidedly a mistake. A resolution to that effect was passed at a general meeting, but was not adopted by the council; and Halley was not only at the pains of superintending the publication of the work, which he had induced Newton to complete, but also undertook to do so at his own risk. The printing was commenced in the summer of 1686, but some delay took place, so that not more than eleven sheets appear to have been finished in February 1687. Halley then resumed his work, which he finally accomplished about the latter end of June 1687; and he must therefore, in this last effort, upon an average, have carried two sheets through the press in each week. This speed was not occasioned, as some have imagined, by any fear of Newton's receding from his engagement. The irritation which he felt in 1686 at Hooke's unfounded claims to a prior knowledge of the true nature and laws of gravitation, induced him to think of suppressing the third book of the "Principia"; but after that irritation had subsided, there is not the slightest indication, in his correspondence with Halley, of any backwardness on his part, in drawing up the work or supplying what was necessary to prepare it for the press.

Royal Premium of the Royal Geographical Society

ON May 14, 1838, Colonel Francis Rawdon Chesney (1789–1872) was presented with the Royal Premium of the Royal Geographical Society. In making the presentation, W. R. Hamilton, the president, said: "You have been the pioneer, to point the way, and to open the road into a large range of country, hitherto imperfectly known; you, and those under your command, have really navigated, for the first time in modern history, two of the most celebrated rivers of the ancient world—the Euphrates and the Tigris; you have added largely to our knowledge of Syria and Mesopotamia, Assyria and Susiana; you have carried a line of levels from Iskanderûm to Bír, and thence along the whole course of the Euphrates to the Persian Gulf; you have laid down the course of the Orontes, from its mouth to Jisr Hadía, and you have done more than enough to secure to yourself a place among the distinguished geographers of our time. These are the grounds upon which the Council of the Royal Geographical Society have judged it right to award to you the first Royal Premium, which the munificence of our illustrious patron, Queen Victoria, has placed at their disposal, for the reward and encouragement of geographical researches."

In acknowledging the honour conferred upon him, Col. Chesney said: "I cannot help feeling some regret, that the rules of the Society do not permit me to urge the claims of those which were greater than mine individually; for I, at least, cannot forget, that the almost unequalled labour of the transport across Syria was chiefly accomplished when I was confined with a brain fever, and that the leading discoveries in geography were made when I was not present." He then went on to refer to the part played in the work of the expedition by Major Escourt, Mr. W. F. Ainsworth, Lieutenant Cleaveland and others.

A Large Montgolfier Balloon

IN the *Athenæum* of May 19, 1838, was the announcement of a proposed "Ascent of the Great Montgolfier Balloon from the Royal Zoological Gardens, Surrey, under the Immediate Patronage of Her Majesty". "On Thursday next, May 24," said the notice, "one of the most extraordinary novelties ever presented to the Public will take place: viz., the Ascent of several Aeronauts with a stupendous new Balloon on the original plan of Montgolfier, of inflation by rarified air instead of gas, being the first Aerial Voyage ever made in England with a Balloon on this principle. It is the largest Aerostatic machine ever fabricated in this country being more than half the height of the Monument, and of proportionate dimensions, and containing 170,000 Cubic Feet of Air. Its vast powers, and the peculiar method of inflation renders this first Ascent unparalleled in the history of Aerostation . . ."

University Events

CAMBRIDGE.—Dr. G. R. Owst has been elected to the newly created professorship of education that comes into operation on October 1. Dr. Owst came up to Emmanuel in 1913 and after an absence for war service took his degree in 1920. He taught in South Africa for the next two years and then returned to England and began to work under Prof. Claude Jenkins at King's College, London, on the subject of medieval preaching. This work and other studies arising from it, have been recognized by the award of D.Lit. London and the Litt.D. Cambridge. Since 1928 Dr. Owst has been an inspector of schools both elementary and secondary and is at the present moment staff inspector for history.

GLASGOW.—Dr. James Small, lecturer in the theory and practice of heat engines, has been elected to the James Watt chair of the theory and practice of heat engines, in succession to Prof. William J. Goudie.

Mr. C. R. Ribbands has been appointed assistant in zoology, in place of Mr. D. S. Bertram, who has joined the staff of the School of Tropical Medicine, as lecturer in entomology.

Mr. H. H. Brown has been awarded the degree of Ph.D. for a thesis entitled "A Study of a Tectibranch Gasteropod Mollusc *Philine aperta* (L.)".

OXFORD.—A. N. Black, Exeter College, has been appointed University demonstrator and lecturer in engineering for four years as from October 1.

The Frazer Lecture for 1938 will be given in the Examination Schools at 5 p.m. on May 23 by Dr. J. H. Hutton, William Wyse professor of social anthropology in the University of Cambridge. His subject will be "A Primitive Philosophy of Life".

Societies and Academies

London

Royal Society (*Proc. A.*, 165, 313–452; April 14, 1938).

E. A. Milne: On the equations of electromagnetism. (1) Identifications. (2) Field theory.

H. J. Gough and W. A. Wood: Crystalline structure of steel at fracture.

Edmund C. Stoner: Collective electron ferromagnetism.

W. Mandell: Resonance in crystal beams of sodium-ammonium seignette salt.

R. B. Randall, M. Benger and C. M. Groocock: Alkaline permanganate oxidation of organic substances selected for their bearing upon the chemical constitution of coal.

Paris

Academy of Sciences, March 14 (*C.R.*, 206, 793–864).

Gabriel Bertrand and Lazare Silberstein: The distribution of boron in the organs of the white lily. The amount of boron in the plant as a whole is small compared with other plants: it is lowest in the stem and highest in the reproductive organs.

Pierre Lejay and Chang Hung Chi: Gravimetric chart of the south of China.

Etienne Halphen: Research on the most independent chance variables.

Aryeh Dvoretzky: The geometrical basis of the theorem of M. Mandelbrojt and analogous theorems.

Béla de Sz. Nagy: The extremal properties of Fourier series transformed by absolutely monotonic series.

Kwok-Ping Lee: The Borel directions of meromorph functions of finite order higher than 1/2.

Carlos Biggeri: The singular points of a Taylor's series external to the circle of convergence.

Georges Dedebant, Michel Kiveliovitch and Philippe Wehrle: A method of establishing the equations of hydrodynamics.

Louis Viaud: An experimental method for the study of an air blast in interaction with the soil.

M. and Mme. Lucien d'Azambuja: The velocity of rotation of solar prominences deduced from their successive passages on the central meridian of the star.

Paul Muller: A new double refracting prism and its application to the measurement of double stars.

V. Frolow: The analysis of the maregraphic series of Norway.

René Lucas: New properties of double refraction of liquids submitted to ultra-sounds. A column of liquid, placed between Nicol prisms set to extinction, shows reappearance of light when the liquid is submitted to ultra-sounds produced by piezo-electric quartz. These optical effects are very clear with some liquids (castor oil, linseed oil) but are inappreciable with others (glycerol, ethyl acetate).

Georges Déchêne: The capacity at the contact of a metal with a semi-conductor.

Frantz Perrier: The determination of the wavelengths of the radiation emitted by electrified insulators: an attempt at a theoretical interpretation. From the measurement of the absorption coefficients in celluloid it is shown that the frequency of the radiation is proportional to the potential difference between the two faces of the dielectric.

Mme. Thérèse Grivet-Meyer: Some properties of the penetrating fraction of the cosmic radiation. The properties of the hard variation vary with the thickness of the total screen interposed. It is not possible to represent the absorption of the radiation by a simple exponential.

Ladislas Goldstein and Anatole Rogozinski: The use of an ionization chamber with a liquid dielectric for the study of neutrons.

Marcus Brutzcus: The thermochemistry of the sulphur compounds.

Mlle. Yvonne Garreau: The constitution of some compounds formed by the oxidation of hydroquinone in the presence of ammonium sulphite or of primary amines.

Tryphon Karantassis and Constantin Vassiliadès: New oxyiodine compounds of the dialkyl derivatives of tin.

Jean Vène: Syntheses starting from the bisulphite derivatives of the camphoric β-aldehyde esters.

Henri Longchambon: Cordierite gneiss and granites in the French Central Massif.

Gilbert Mathieu: The structure of the island of Yeu.

Louis Eblé and Gaston Gibault: The values of the magnetic elements at the Observatory of Chambon-la-Forêt (Loiret) on January 1, 1938.

Georges Dubois and Mme. Camille Dubois: The peats of Cragou (Finistère). Results of pollen analyses: the Cragou peat is relatively recent, neolithic.

Georges Deflandre: Study of the organic materials forming certain fossil plankton microorganisms. Attempts at microchemical analysis. Results of the application of various staining reagents. The present ideas on the microchemistry of cellulose membranes, or of similar composition, based on the study of existing bodies or living beings, cannot be applied to plankton microfossils.

Mlle. Marie Celan: The structure of the central cells of *Halopitys pinastroides*.

Arthur Brunel: The degradation of substances of puric origin in the lamellibranch molluscs. *Mytilus edulis* possesses the property of degrading uric acid to urea and ammonia: allantoin and allantoic acid are the intermediate terms of this reaction.

Michel Macheboeuf and Francois Tayeau: The state of the lipids and of cholesterol in the blood serum: the destruction of certain lipidoproteinic cenapses and the liberation of their lipoid substances by a soap.

Gustave Guittonneau and René Chevalier: The attack of the benzene nuclei and the utilization for food of phenol by the *Azotobacter* of the soil. A strain of *Azotobacter* has been cultivated which grows on silicogel containing phenol, and which also grows on media containing mannitol, sodium benzoate, sodium *p*-oxybenzoate, but does not develop in the presence of *m*-oxybenzoate or *o*-oxybenzoate. This would appear to be a new physiological type of *Azotobacter*.

Moscow

Academy of Sciences (*C.R.*, 18, No. 2, 1938).

S. Sobolev: A class of integro-differential equations with several independent variables. (2).

K. Persidskij: The law of large numbers.

K. Brodovitskij: Statistical analysis of the rhythm of fundamentally unobservable regularities, observed manifestations of which are subject to some unknown perturbations.

I. M. Goldman: Breakdown of compressed nitrogen in small gaps.

E. Gross: The splitting-up of the Rayleigh line and the acoustic spectrum of crystals.

P. Petrenko-Kiritschenko: The law of periodicity.

M. V. Gorlenko: Resistance of winter wheats to black bacteriosis (*Bacterium translucens* var. *undulosum* S.J.R.).

A. A. Isakova and A. A. Andrejev: The excretion of nitrogenous compounds by the roots of leguminous plants (lupin) and the conversion of these compounds in the presence of bacteria.

M. Abakumova: Problem of photo-periodical and temperature after-effects.

V. G. Aleksandrov and O. G. Aleksandrova: The flintiness and flouriness of wheat endosperm.

N. G. Chlopin: Attempt at an experimental analysis of the auxiliary components of the nervous system.

J. A. Vinnikov: Growth and transformation *in vitro* of myoneural elements (sphincter and dilator of the iris).

V. P. Michailov: Growth and transformation *in vitro* of the covering cells of the vascular plexuses of the brain.

N. N. Kannegisser: Growth and transformation *in vitro* of the elements of the pia mater.

G. A. Schmidt: Ectoderm of the Anuran gastrula under the inductive influence of dead organizers and parts of organs of Amphibia and mammals.

Tokyo

Imperial Academy (*Proc.*, 14, No. 2, 27–85, Feb. 1938).

S. Kakutani: The uniqueness of Haar's measure.

Shin-ichi Izumi and Tatsuo Kawata: Notes on Fourier series. (3) Absolute summability.

Hitoshi Hombu: The projective theory of 'paths' of the third order

$$x^{(3)i} + H^i(x, x^{(1)}, x^{(2)}) = 0.$$

Kenzo Joh: A theorem of K. Löuner on univalent functions.

Masao Sugawara: Siegel's modular function of the higher degree.

Hantaro Nagaoka and Tadao Mishima: High terms of Paschen series in hydrogen and deuterium.

Ken Sugawara: Decompositions in shallower waters of a lake in summer and the supply of oxygen from the atmosphere.

Masao Kubokawa: Activated adsorption of methane on reduced nickel.

Shigehiko Sugasawa, Kûchiro Kakemi and Tôru Tsuda: Synthesis of 6,7-dimethoxyquinoline.

Hidekichi Yanagisawa and Eûchi Yokoi: Purification of hirudin, an active principle of *Hirudo medicinalis*.

Tetûchi Kobayashi and Hisashi Mochizuki: Outline of the structure of the Kibi plateau on the inner side of western Japan.

Saburô Ôishi: The Japanese equivalents of the *Lepidopteris* and *Thaumatopteris* zones of East Greenland.

Gihei Yakama: (1) Hydrogen ion concentration, etc., of the anther sap of *Lilium* species. (2) Potential measurements of the dividing pollen mother cells of *Lilium speciosum*.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, May 16

King's College, London, W.C.2, at 5.30.—Prof. Th. J. Stomps: "Recent Developments of the Mutation Theory".*

Wednesday, May 18

Royal Society of Arts, at 8.30.—Prof. K. W. Braid: "Bracken and its Present Menace to Heather and Pasture".

Thursday, May 19

Royal Society, at 2.30.—Discussion on Turbulence in Fluid Motions, to be opened by Prof. G. I. Taylor, F.R.S.

London Mathematical Society (at the Royal Astronomical Society, Burlington House, W.1), at 5.—Prof. W. V. D. Hodge: "Harmonic Integrals".

British Institute of Radiology, at 6.30.—Annual General Meeting.

Sir John Cass Technical Institute, Aldgate, London, E.C., at 7.—A. J. Murphy: "The Selection of Non-Ferrous Materials for Engineering Purposes" (succeeding lectures on May 26 and June 2).*

Chemical Society, at 8.—Discussion on "Organic Intermolecular Complexes". Opened by Prof. G. M. Bennett.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant Engineer and Civil Engineering Assistants in the Roads Department of the Ministry of Transport—Assistant Secretary, Establishment Department, Ministry of Transport, Metropole Buildings, Northumberland Avenue, W.C.2 (May 16).

Lecturer in Mathematics (woman) in Darlington Training College—Principal (May 18).

Senior Scientific Officer in the Directorate of Civil Research and Production, Air Ministry—Permanent Under-Secretary of State, Air Ministry (S.2.d.), Adastral House, Kingsway, W.C.2 (May 20).

Scientific Officer, Junior Scientific Officer, Technical Officers and Assistants (II) for work on wireless apparatus, etc., at the Signals Experimental Establishment, Woolwich, S.E. 18—Superintendent (May 20)

Lecturer in Physiology in the University of Queensland—The Secretary, Universities Bureau of the British Empire, 88A, Gower Street, London, W.C.1 (May 20).

Assistant Lecturer in Chemical Pathology in the University of Manchester—Registrar (May 21).

Senior Scientific Officer in the Admiralty scientific pool (physics, particularly acoustics)—Secretary to the Admiralty (C.E Branch) quoting Ref. No. C.E. 3326/38 (May 21).

Lecturers in Mathematics, Physics, Chemistry, and Civil and Mechanical Engineering Department of Woolwich Polytechnic, S.E 18—Secretary (send stamped addressed envelope) (May 21).

Two Assistants (one with knowledge of aeronautics) in the Civil and Mechanical Engineering Department, a Lecturer in Chemistry and a Lecturer in Mathematics in the Northampton Polytechnic, St. John Street, London, E.C.1—Secretary (May 23).

Lecturer in Zoology in King's College, Newcastle-upon-Tyne—The Acting Secretary to the Council (May 25).

Pathologist and Bacteriologist at the Memorial Ophthalmic Laboratory, Cairo—Horace H Rew, Examination Hall, Queen Square, London, W.C.1 (May 28).

Head of the Department of Physics at the Chelsea Polytechnic, London, S.W.3—Principal (May 28).

Chemists in the War Department—Under-Secretary of State (C.5), War Office, S.W.1, quoting Appts./83 (May 28).

Lecturer in Mathematics and Lecturer in Chemistry in the Derby Technical College—Clerk to the Governors (May 28).

Assistant Meteorologist in the Meteorological Service of the Sudan Government—The Controller, Sudan Government, London Office, Wellington House, Buckingham Gate, London, S.W.1 (May 31).

Bacteriologist in the Veterinary Department in Kenya—Director of Recruitment (Colonial Service), 8 Buckingham Gate, London, S.W.1 (May 31).

Demonstrator in the Department of Zoology at Bedford College for Women, Regent's Park, N.W.1—Secretary (May 31).

Lecturer in the School of Agriculture near Khartoum—University Appointments Board or Controller, Sudan Government (London Office), Wellington House, Buckingham Gate, S W.1, marking envelope "Lecturer" (May 31).

ASSISTANT METEOROLOGIST in the British West African Meteorological Service—Director of Recruitment (Colonial Service), 8 Buckingham Gate, London, S.W 1 (May 31).

ASSISTANT LECTURER IN ELECTRICAL ENGINEERING in the Manchester Municipal College of Technology—Registrar (June 1).

LECTURER IN BIOLOGY in the School of Science, Khartoum—The Controller, Sudan Government, London Office, Wellington House, Buckingham Gate, S.W.1 (June 1).

PRINCIPAL of the Marine School, South Shields—The Secretary (June 1).

ASSISTANT IN THE DEPARTMENT OF ARCHÆOLOGY in the Leicester Museum and Art Gallery—The Director (June 11).

DEMONSTRATOR IN ANATOMY in the University of Sheffield—Registrar (June 15)

LECTURER IN ZOOLOGY (marine zoology or physiology) in the University of Sydney—The Secretary, Universities Bureau of the British Empire, 88A, Gower Street, London, W.C.1 (July 12).

JUNIOR RESEARCH INVESTIGATORS in the British Non-Ferrous Metals Research Association—Secretary, B N.F.M.R.A., 1–6, Regnart Buildings, Euston Street, London, N.W.1

INSTRUCTOR IN RADIO ENGINEERING for the Education Department, Straits Settlements—Crown Agents for the Colonies, 4 Millbank, London, S W.1, quoting M/5561.

LECTURER IN CHEMISTRY with qualifications in physical chemistry in the University of Reading—Registrar

LECTURER IN ELECTRICAL ENGINEERING in the University of Birmingham—Secretary.

Broadcasting as a Social Service

IN the admirable essay on the British Broadcasting Corporation in the volume of essays "Public Enterprise: Developments in Social Ownership and Control in Great Britain" by a group of contributors belonging to or associated with the New Fabian Research Bureau, Dr. W. A. Robson, while recognizing the achievements of the Corporation, the merits of its organization and the high degree of public spirit in its staff, referred to the deplorable absence of serious criticism and intelligent information concerning broadcasting in Great Britain. The general public indeed is scarcely aware either of the achievements or the shortcomings of British broadcasting, or the possibilities and the dangers of broadcasting as affecting international relations.

A more searching and discriminating attitude towards broadcasting activities is undoubtedly essential if the vitality and future progress of broadcasting are to be assured, and the same plea is advanced in Dr. Cleghorn Thomson's recent suggestive survey of radio development and its problems in our changing world under the title "Radio is Changing Us". Dr. Cleghorn Thomson writes in a disarmingly bantering tone but never loses sight of the serious aspect of his thesis. His seven years' experience inside the British Broadcasting Corporation add weight to many of his criticisms, although his attitude is that of the keen listener, and he lays his main stress on the importance of creative imagination in the development of broadcasting services whether in Great Britain or elsewhere.

Without a more critical approach to broadcasting problems and a more imaginative and creative appreciation of the social and cultural elements involved, technical development is likely to lag far behind what is possible, and much of the value of efforts, such as those of the International Broadcasting Union and the International Committee on Intellectual Co-operation, to use this new means of spreading information in the service of peace and understanding between the nations, may well be lost.

The problems and difficulties so far encountered are, of course, essentially those which have been raised and stressed repeatedly of late, notably in Mr. T. H. O'Brien's study of "British Experiments in Public Ownership and Control" and in the essays on the British civil servant edited by Dr. W. A. Robson. Fundamentally, the problem is one of linking efficient administration and effective safeguards against abuse or damage to the public interest with the creative imagination which is alive to the human and social issues involved and the service which technical developments can render to them. It is this which has brought into the forefront at the present time the whole question of training for administration, and the importance of securing those who possess the scientific background to assess technical factors as well as creative ability and the capacity to promote energetic and far-reaching projects. Caution and regard to existing interests can never be a substitute for vision and initiative; and the severest criticism that has been made of the Governing Board of the British Broadcasting Corporation is just that its personnel does not inspire confidence in its contact with progressive thought, its receptivity to new ideas and its capacity to promote energetic development. It suggests the retrospective rather than the forward-looking mind which is so imperatively needed in such positions to-day.

Statements in the Press that the quality of broadcasting programmes in Great Britain is likely to be affected by the financial stringency through which the British Broadcasting Corporation is passing give further point to some trenchant criticism by Dr. W. A. Robson in the essay to which we have alluded. Dr. Robson notes that the British Broadcasting Corporation, a public service undertaking carried on without a divisible profit on a self-supporting basis, has been required over a long period of years to pay to the Treasury out of its licence revenue not only a heavy percentage deduction amounting in 1934 to £1,134,315 out of £3,369,000 but also a series of "emergency contributions" levied annually to meet the financial crisis of 1931, amounting in 1934 to £187,500, as well as a further sum by way of income tax amounting to £113,000 in the same year. Thus in 1934, out of each ten shillings paid for a licence, only 4*s*. 9*d*. was available for broadcasting, and, though the Government has accepted the view of the Ullswater Committee that the Corporation should receive a larger share of the licence revenue, the change is estimated to bring the net licence revenue in 1937–38 to £2,800,000, on which basis about 6*s*. 5*d*. out of the ten shilling licence will be available for the broadcasting service.

This, therefore, is a step in the right direction; but on any broad or long-range view of the broadcasting service these payments must all be regarded as unjustifiable. They are drained out of the broadcasting revenue derived from the licence fee at the expense of the listener, and are due to demands made by the Treasury, regardless of the purposes for which new enterprises are run.

What is needed here is, of course, some central planning organization which is competent not merely to stimulate such a philosophy of public finance, but also to assess the significance of broadcasting as an element in the social services or educational system of the nation, and to determine the broad lines along which it can work out its own policy and contribution in harmony with other public or social services. Only in such a way can we be sure that adequate financial resources will be available, and machinery developed for co-ordinating the work when required and avoiding friction or overlapping between different public utilities or services.

This is, of course, a matter involving much more than questions of finance alone. It affects questions of technical development, the recruitment of staff and most matters in which the utilization of creative thought, a scientific outlook and progressive opinion are concerned. Above all, it means constructive and fundamental thought about the place of broadcasting in national economy and its contribution to cultural or social development as a basis for the framing of a policy. Moreover, if, as Mr. Cleghorn Thomas holds, it is in its contribution to the fuller and more abundant life—in the stimulation of intellectual life and individuality in the arts, the sciences, the humanities —that broadcasting can most permanently justify itself, the fullest opportunity for its expression can only be secured when those in direct or indirect control of it are fully alive to the opportunities it holds and in sympathy with the service it can render to humanity.

The danger indeed is not greater in the financial than in the political or other spheres. Indeed one reason why the public should be afforded much more information about the expenditure of the British Broadcasting Corporation, as urged by Dr. W. A. Robson and Mr. T. H. O'Brien, is to facilitate an intelligent understanding of the work which the Corporation is doing and the way in which financial difficulties hamper development. The attention focused upon staff problems and especially recruitment by Dr. Herman Finer in his essay in "The British Civil Servant" is of significance because of the vital importance of securing staff and conditions of service in which the psychological atmosphere is favourable to creative thought and imaginative development. The relations of the Corporation to the Government and the composition of its Governing Board similarly not only affect these matters but also the firm establishment of continued belief in the impartiality of the Corporation, its freedom from propaganda and prejudice and its willingness and ability to serve the changing needs of the public to the maximum of its opportunities, both within the territorial limits of the nations and on the international scale also. The appeal for constructive criticism which is so striking a note in Mr. Cleghorn Thomson's book and in the other essays we have noticed is founded on the belief that only by such means can an institution be assisted to develop its services and keep itself imaginatively alive to the magnitude of its opportunities. In such criticism scientific workers have a part to play which has special claims upon their interest, because of the rapidity with which the problems presented have themselves arisen out of the application of scientific discovery and thought.

From Galileo to Einstein

The Evolution of Physics:
the Growth of Ideas from the Early Concepts to Relativity and Quanta. By Albert Einstein and Leopold Infeld. (Cambridge Library of Modern Science.) Pp. x+319+3 plates. (Cambridge: At the University Press, 1938.) 8*s*. 6*d*. net.

THE interpretation of science to the lay reader—and we may quite candidly admit that 'lay reader' must be interpreted as including practically all men of science who do not happen to be professionally interested in the particular branch of science under consideration—is a task both important and difficult. Of books which might be described as being suitable for some "Wonders of the Universe" series there is an excellent supply, and very good some of them are. The universe *is* a wonderful place, and to explore it under the guidance of a distinguished cicerone is both pleasant and profitable. Too often, however, one lays the book down with an uneasy feeling that something is missing. It reads like a detective story from which all the middle pages are missing. The first chapter, with its neatly arranged pile of corpses, is there, and the last page or so in which the name of the villain is disclosed; but the account of the search, and in particular, that thrilling chapter, near the end, where the 'little grey cells' come into play, is wanting, and the real interest of the book has vanished with it. While it is, no doubt, edifying to learn that a lump of matter is nothing but a whirl of flying electric charges, what the reader would like to know, and what it is important that he should know, is how, and by what stages, the physicist arrives at this astounding conclusion. If, as Prof. Einstein and his co-author claim, "Physics is a creation of the human mind, with freely invented ideas and concepts", it is this intellectual content which gives to physics one of its chief claims to cultural significance, and provides for the thoughtful non-technical reader his main source of interest in it. It is with this aspect of the subject that the authors are concerned in this very distinguished book.

The fact that they are "mainly concerned with the role of thoughts and ideas in the adventurous search for knowledge in the physical world" makes the task of the authors at the same time easier and more difficult. On one hand they can, and do, dispense with the experimental and mathematical scaffolding which is so terrifying to the lay reader—there is not a single mathematical equation in the whole book; on the other, the concepts of modern physics (though the authors describe them as "simple and natural") are by no means easy to grasp. The historical approach was obviously the one which offered the best chance of success, and, as the title implies, it is the historical method which the authors have chosen. "Our aim will be accomplished", they write, "if these pages give you some idea of the eternal struggle of the inventive human mind for a fuller understanding of the laws governing physical phenomena".

A fascinating story they make of it. The first chapter sketches the rise of the mechanical theory of the universe, from Galileo to Newton, from Newton to Joule and the kinetic theory of matter. The second chapter foreshadows difficulties for the hitherto triumphant mechanical view of Nature, in the discovery of the curious interrelation between the electric and magnetic fields, and in the wave theory of light. The difficulties were not felt very seriously at the time—in fact, the ether wave theory of light was regarded as one of the highest achievements of mechanical theory. Nevertheless, attempts to construct a reasonably acceptable model of the electromagnetic field, or to assign consistent mechanical properties to the luminiferous ether, all ended in failure. The conclusion is drawn that the trouble lies in the fundamental assumption that it is possible to explain all events in Nature from a mechanical point of view.

A new chapter opens with Faraday's discovery of electromagnetic induction, and Maxwell's conception of the electromagnetic nature of light. From this it is a short step to the problem of the ether drift and the decisive experiments of Michelson and Morley. The stage is now set for the introduction of the principle of relativity, an exposition of which, both in its restricted and in its general form, occupies the rest of the chapter. The story here reaches a true climax. The gathering difficulties; the search for a weak link in the apparently unbreakable logical chain of reasoning constituting the classical mechanical theory which nevertheless had led to predictions that experiment had failed to confirm; the final resolution of the difficulty in the principle of relativity is set forth with a genuine excitement, which betrays that the author was also an actor in the drama which he portrays. A final chapter on quanta reveals that "the eternal struggle" is far from having reached its final phase.

It will be evident from this brief synopsis that the authors have made no attempt to cover the whole of physical theory—they have followed only one of its main channels. How far they have succeeded in their gallant attempt to make clear to the intelligent non-technical reader the fundamental conceptions of modern physics, the reader himself must decide. He may at any rate be assured that he is unlikely to find a more authoritative, lucid or genial guide. Although no previous technical knowledge is assumed, the book is not easy reading; indeed, no book of this kind can be that, unless its author has shirked the real difficulties of his task; and Prof. Einstein is not the man to shirk difficulty. What can be done by a singular lucidity of style, by apt illustration, and by occasional flashes of humour to smooth the path, the authors have done. The reader who pursues the path to its end will find that it brings him very near to the heart of physics. This is a book of real distinction, which no one interested in physical and philosophical ideas can afford to neglect.

J. A. CROWTHER.

Problems of National Survival

Political Arithmetic:
a Symposium of Population Studies. Edited by Lancelot Hogben. Pp. 531. (London: George Allen and Unwin, Ltd., 1938.) 30*s*. net.

"THE present volume sets forth some of the enquiries undertaken by the Department of Social Biology [of the London School of Economics and Political Science] during the Editor's tenure of office therein. . . . About half of the material is presented for the first time. Any profits arising from the sales will be devoted to the publication of other *factual* social studies."

The title of this collection of essays devoted to "realistic social enquiries" derives from the "Politicall Arithmitick" (1691) of William Petty, the "man of affairs" who was one of the founders of the Royal Society. The choice of title is appropriate in that, though probable (or standard ?) errors and correlation coefficients are given in places, quite elementary methods are still used, these being mainly discriminating tabulation and interpolation by proportional parts. The result, however, is an impressive contribution to the investigation of problems which are ever more urgently being thrust upon us.

The chapters are grouped under two headings: "The Survival Minimum" and "The Recruitment of Social Personnel". The thesis implied in the former is that "the rate of reproduction has sunk below the limit compatible with continued survival in many countries". This is established by studies of trends of fertility, mortality and nuptiality in Great Britain and in Australia; but the first chapter, by Dr. Kuczynski, deals with the international decline of fertility, while the last, by the same author, is a reprint from the *Annals of Eugenics* of a carefully documented and illuminating article, "British Demographers' Opinions on Fertility, 1660 to 1760". The second part is chiefly concerned with "a field of enquiry which has been conspicuously neglected" yet is less highly speculative, namely, in particular, the waste of ability in the denial of opportunities of study to many who would profit from further study, and conversely, due to the structure and working of English education. The relation of this wastage to parental occupation is also investigated. Further, the inducement we give to juveniles to take up unskilled work is exposed, and the differential fertility of skilled and unskilled wage-earners examined. A final chapter on an unrelated topic, the distribution of the blood-groups and its bearing on the concept of race, gives a very useful synopsis of the facts and a careful examination of what is involved in classification; this chapter also has a bibliography.

The general tone of the book suggests that it is but a preliminary attack on the problems to be studied; in fact, after the manner of the pioneers of the Royal Society with regard to British agriculture, a programme of "heads of enquiries" has been prepared with the help of a group of economists. The volume will certainly be convenient as a starting-point or a source of data, even for those who are using more advanced methods in the approach to population problems. A book like this should win recruits to these studies, and it would have been still more usable had it contained an index, or even a detailed table of contents. The excellent summaries at the end of most chapters do not compensate for this lack.

In the introduction to Part I, Prof. Hogben gives an outline of the tradition to which the work belongs, and incidentally makes an almost medievally vigorous attack on the scholastic tradition which he finds dominating the modern teaching of economics. It is in response to this tendency, he says, that Malthus "the phlogistonist of demography is far better known than Petty or Graunt".

We are attracted by "self-evident principles", rather than aware of the importance of definite data or of the possibilities of changing the facts of our social relations. This attitude is evidence of the stimulating, and possibly provocative, character of this work. Like medicine, economics must be indubitably freed from complete submission to merely deductive methods.

It is unfortunate, however, that in producing a book that is to be used, a little more care had not been given to ensure that the task of appreciating masses of data was made as little burdensome as possible. The difficulty in facing up to such appreciation may be essentially educational—how make it possible not to be oblivious to all save over-simplified ideas, such as those of Malthus ? How encourage a vigorous openmindedness ? For this reason it seems well to emphasize the obvious, that those who have been able to steep themselves in the details of such topics may be forgetful of how difficult it is for most who come fresh to them to get a satisfactory viewpoint.

Graphs are freely used in most of the chapters here, but it is not realized how depressing is the meticulous marking of all the graduations of a scale—indeed the over-detailed yet ambiguous marking of the class scale in Fig. 1 of page 126 raises doubt as to consistency with Table I of p. 108 ; the marking of a couple of salient graduations gets the range of variation most easily into perspective. The tables of gross reproductive rates, occupying pp. 54–59, would have been more readable if rows and columns had been interchanged. Comparison would have been facilitated had closely related maps been printed together on a folded sheet ; and so on with such elementary matters.

But one wonders that, while the project of Petty for "A Dictionary of Sensible Words" is so strongly commended, this is neglected in a book which is in danger of being rather loosely knit. Progress in such studies has consisted in considerable degree in a refinement of the criteria to be applied, and reference to an authoritative list of the definitions of the various possible 'coefficients' would relieve the strain on those who have to form a fresh judgment as to which criteria are appropriate in particular cases. Some of the chapters too could with advantage be more fully documented ; this can be remedied in a second edition. J. M.

Gas Attacks and Defence

Breathe Freely ! the Truth about Poison Gas
By Prof. James Kendall. Pp. xi+179. (London : G. Bell and Sons, Ltd., 1938.) 3*s*. 6*d*. net.

In calculating the chances of air raids being carried out against Great Britain, Prof. Kendall thinks that Germany is the only nation that need be seriously considered, and it is on her policy that everything really depends. In his opinion, it is unlikely that there will be another war with that country in this generation, so that German air raids constitute, in the present state of Europe, nothing but an empty threat ; but if they should come, and gas is used, it would be ineffective provided that adequate preparations are made and reasonable precautions are taken against it.

Prof. Kendall says that chemists are absolutely confident that no 'super gas' has been found, and he thinks that it is most unlikely that since the Great War poison gases have been discovered which are markedly superior to phosgene as an offensive weapon or to mustard gas as a defensive one. In fact, gas is only likely to be used in future if one side has a desperate reason for its employment and when effective retaliation is either impossible or likely to be impracticable owing to the demoralization caused. Germany no longer enjoys a monopoly in chemical manufacture, so that she can never again depend on a six-months start over her opponents. If she failed after taking this step, she would be shown no mercy a second time and would be ruled with a rod of iron for generations.

The author refers at some length to the scare-mongers and he exposes their extravagances : "It is all so pathetic and at the same time such arrant rot" ; and he even comments on the disproportionate effort expended by the Home Office on anti-gas instruction in its Air Raid Precautions Handbooks. This seems a little unreasonable, because there was an obvious need for instructing an ignorant and apathetic public. It was only by stressing the danger—within limits—that an effect could be produced, and once this danger was realized adequate preparations would do much to render gas ineffective, so that the inclination to use it would be discouraged, and one at least of the risks of an air raid would be eliminated.

While instructed readers will be in general agreement with the author in the main purpose of this book, they will not so readily accept his conclusions when he makes excursions into regions outside his own province. For example, with the experience of the prolonged and dangerous situation caused by a civil war in Spain—a second-class country—is a general European war within the next few years "exceedingly improbable" ? Prof. Kendall says that barking dogs never bite, but when good faith is lacking, armaments are mounting, militarism is being inculcated in the whole youth of the totalitarian States, and recent aggressive steps have met with such astonishing success, it seems more probable that the next moves are merely a matter of opportunity and careful timing ; and that Great Britain would be drawn, however unwillingly, into any conflict between first-class Powers, regardless of the apparent limitations of its existing treaty engagements.

Does the use of gas merely involve a prolongation of hostilities ? If chemical warfare had continued into 1919, would the main bodies of troops have taken shelter in huge dug-outs while squads of men relieved each other at frequent intervals in the exhausting task of decontaminating scores of square miles of territory ? Are the huge new blocks of flats in Germany much more vulnerable to incendiary bombs than the isolated houses which predominate in British towns ? Were the casualties sustained by the German troops caused by the imperfection of what their commanders termed their "iron gas discipline", or rather by the various weaknesses of human nature which would be displayed to a much more pronounced extent by a civil population ?

However, these expressions of opinion are not the primary object of the author, which is to examine in an impartial way the possible use of gas and its probable effects in an air raid. Even if he has told us nothing new, he has succeeded in placing the actual facts before the public in proper perspective, so that "the way to avoid Bedlam is not to go insane in advance".

C. H. FOULKES.

Extinct Mammals of the Western Hemisphere

A History of Land Mammals of the Western Hemisphere

By Prof. William Berryman Scott. Revised edition, rewritten throughout. Pp. xiv+786. (New York : The Macmillan Co., 1937.) 32*s*. net.

A PERIOD of a quarter of a century has elapsed since the first appearance of Prof. W. B. Scott's admirable account of the mammals of the western hemisphere. The new edition that has just appeared gives a measure of the increase in our knowledge of extinct mammals during this time, the result of praiseworthy activity on the part of many museums of the United States and Canada. This increase has necessitated so much revision and rewriting that, with the exception of the title and a couple of chapters, the work is more properly to be described as a new book than as a new edition. There are also more than a hundred additional figures, including many new restorations.

The author in the preface to his first edition said that so rapid was the uninterrupted course of discovery that parts of the text became antiquated while in the press. The same statement could still be repeated to account for the absence of notice of the late W. D. Matthews' work on the fundamentally important Palæocene fauna of New Mexico which, published last year, appeared too late for incorporation. On the other hand, most new results or discoveries of scientific interest that were available seem to have found a place and their first home in a general text-book. The skull of *Thylacosmilus*, a sabre-toothed marsupial which, when compared with the totally unrelated sabre-toothed tiger *Eusmilus*, gives as striking an instance of convergent and highly specialized adaptation as one could hope for; and, to quote only one more example out of many, the radiation into numerous and bizarre forms of antler in the pronghorn and other deer families described by Child Frick, are examples of recent discoveries.

The author also in his preface states that his book is written for the "non-professional" and that "perhaps it is unjustifiable optimism to assume the existence of a body of readers of this subject", but that he hopes that nevertheless they are to be found. It is much to be hoped that this book itself will create such a body, once they are introduced to this fascinating subject of mammalian palæontology. The first four chapters are introductory and are by no means unduly technical, so that the "non-professional" reader should be able to continue to the end with increasing interest. It is, however, the professional palæontologists, who, knowing the difficulties that have to be surmounted in the production of a summary account of so wide a field, will be the ones that feel not only interest but also admiration for Prof Scott's achievement.

The Linnean Society

A History of the Linnean Society of London
By Lieut.-Colonel A. T. Gage. Pp. 175 + 11 plates.
(London: Taylor and Francis, 1938.) 5*s.*

THE hundred and fiftieth anniversary of the founding of the Linnean Society of London, which is being celebrated on May 24–27, is a very suitable occasion for the publication of its history. Several previous attempts to compile the history of the Society had been made, but they did not come to fruition. In Colonel Gage, the Society was fortunate in finding not only an energetic and faithful historian, but also one whose intimate knowledge of the Society and its archives rendered him peculiarly fit to put on record the growth and development of the Society and the vicissitudes through which it has passed.

The hundred and fiftieth anniversary is an occasion for the fellows to praise great men and the fathers that begat the Society, that triumvirate James Edward Smith, who had purchased the Linnean collections and books, Samuel Goodenough and Thomas Marsham, for many years president, treasurer and secretary of the Society respectively. But just as many infants pass through very critical periods in their lives, so the Linnean Society, after some years of initial prosperity, found its meetings becoming poorly attended and the subscriptions of its fellows less regularly paid. To crown these difficulties, the president, Sir James E. Smith, moved from London to Norwich in 1796, taking the Linnean collections and books with him. This was like removing the Ark of the Covenant from the Temple. To counteract these difficulties, some active fellows urged the obtaining of a charter for the Society, and this display of energy as well as the enhanced prestige which the Society obtained thereby, had the desired effect, and by the beginning of the nineteenth century the Society had attracted more than two hundred members.

Smith, though absent from London, remained president of the Society for forty years, until his death in 1828, when his executors offered to sell to the Society the collections and library of Linnæus, together with other specimens and books acquired by Smith, for the sum of £5,000. With great difficulty, but with superb courage, the Society managed by various expedients to raise the necessary funds and thus regained possession of the collections, the free use of which, while their president lived in London, had formed a centre of attraction for the fellows and had inspired the name of the Society.

There were other difficult times to live through. The hiving off (in 1826) of the Zoological Society no doubt took away some members and prevented some potential ones from joining, though the main object of the new Society was the maintenance of a Zoological Garden rather than the furtherance of scientific zoology. This is indicated by the election of Thomas Bell, professor of zoology at King's College, to the presidency of the Linnean Society in 1853, though he was for eleven years a vice-president of the Zoological Society. Incidentally, it may be mentioned that he was one of the most active presidents the Society has ever had. He introduced the idea of annual presidential addresses and also the discussion of papers after they had been read at the general meetings.

Other critical periods were due to internal dissention on questions of procedure and some on policy, as when the admission of women to the Society was being urged and ultimately agreed upon in 1904. In connexion with this innovation, Colonel Gage shows conclusively that it was not made, as has been suggested, with a view of improving the finances of the Society.

The continued prosperity of the Society may be summed up in the words, slightly altered, which the president Carruthers used when referring to the centenary meeting. "The story of the Linnean Society during the last 100 years is the history of Biology". The names of such leading fellows as James Edward Smith, Robert Brown, Bentham and Hooker, Wallace and Darwin, and all they stood for, more than justify the existence of the Society Its future prosperity and usefulness depend upon its power to adapt itself to new conditions and to the further development of the biological sciences. Colonel Gage does not merely praise the past, he is rightly critical of many actions of former presidents and councils, and future members of the latter will do well to study the history now under review. It may enable them to avoid possible difficulties, and in addition they will find much valuable information in the later chapters of the history, which deal with the publications, the library and the finances of the Society.

The future fellows of the Society, like the present ones, will, we are sure, be deeply grateful to Colonel Gage for his careful and painstaking history, carried out with courageous determination in spite of considerable set-backs due to ill-health. It will remain an enduring memorial of the handiwork of a faithful and discerning fellow of the Society.

Reports of the Progress of Applied Chemistry

Issued by the Society of Chemical Industry. Vol. 22. Pp. 818. (London: Society of Chemical Industry, 1937.) n.p.

THIS annual volume fully maintains the high standard which chemists and chemical manufacturers have learned to expect. It is presented in the traditional form of sectional reviews on the principal branches of applied chemistry, fully documented by reference to the relevant technical literature and patent specifications, and to abstracts thereof published by the Bureau of Chemical and Physiological Abstracts. The series is therefore almost indispensable to anyone taking an active interest either in the progress of chemistry or in the advancement of any branch of industry which involves the use of chemical operations, a knowledge of the chemical composition or behaviour of materials, or the employment of chemists for control or research. Further, it is a convenient guide-book in the hands of those who wish merely to take a bird's-eye view of modern technology in its chemical aspects.

The present issue deals, *inter alia*, with fuels, with dyes and textiles; with paper, glass, cement, steel, drugs, oils, paints, rubber, leather, sugar, and soil; with foods and water; with electrochemistry and photography. Explosives, which are treated biennially, do not appear in this volume. The section dealing with bleaching, dyeing, printing, and finishing has this year been incorporated with that on fibres, textiles, and cellulose, the combined chapter occupying between eighty and ninety pages.

Name and subject indexes are provided.

A. A. E.

Fermente, Hormone, Vitamine:

und die Beziehungen dieser Wirkstoffe zueinander. Von Dr. Robert Ammon und Dr. Wilhelm Dirscherl. Pp. xvi+451. (Leipzig: S. Hirzel, 1938.) 30 gold marks.

EULER has classified the hormones and vitamins together as "ergones", and has laid stress on the fact that ergones may act as coferments. The best examples are vitamins B_1 and B_2, which are important parts of the molecules of cocarboxylase and Warburg's yellow ferment. It seems probable that many ergones may act by influencing enzymes. The authors of the present book class together as "ergines" all the organic substances which act in small doses—enzymes, hormones and vitamins. These groups interact in many ways and are conveniently considered together.

The book is written from the point of view of the biochemist, but clinical observations are also discussed. Authorities are not quoted with full references; but the author's name and the year are usually mentioned, and there should be no serious difficulty in tracing the originals. The book contains much information and is usually fairly accurate, but uncritical. The vasodilator substances which are found in tissue extracts are included as *Gewebshormone*. The work of Rowntree and his collaborators on the thymus is not mentioned.

Land of Ice and Fire

By Hans Wilhelmsson Ahlmann. Pp. xiii+271+16 plates. (London: Kegan Paul and Co., Ltd., 1938.) 12*s*. 6*d*. net.

THE Vatna Jökull of Iceland, with an area of well over three thousand square miles, is larger than any other glacier in Europe. It is rugged, crevassed and even chaotic in parts, and is associated with an undue share of fog, wind, snow and rain. The heavy precipitation and the extensive ablation make it an area of important investigation into the relations between the growth and wastage of glaciers. From time to time it has been crossed, notably in 1932, when the Cambridge expedition, which is not mentioned in this book, made a double traverse.

Prof. Ahlmann's Swedo-Icelandic expedition of 1936 was designed to penetrate the eastern interior of the ice sheet, chiefly in order to measure growth and wastage. This entailed the digging of pits in which the thickness of each year's accretion could be seen and the planting of surface posts against which wastage could be noted. It is not an easy area in which to travel, and in Prof. Ahlmann's book the task loses nothing of its reputation for difficulty, but there were some fine days and on the whole the expedition achieved its aims, though this book does little more than touch on the conclusions.

However, the work of the expedition was not confined to Vatna Jökull. Several other parts of Iceland were visited, and there is much of interest in the account of peasant life in Iceland and the struggle with adverse soil and climate that Icelandic agriculture and stock raising have to face. These chapters give a good picture of modern Iceland. It is a pity that the translation from the Swedish is somewhat laboured and in places lacking in idiomatic English usage. The photographic illustrations are excellent, and the map, though rather meagre, serves its purpose.

R. N. R. B.

The Dissection and Study of the Sheep's Brain:

as an Introduction to the Study of the Human Brain. By James Wilkie. (Oxford Medical Publications.) Pp. xvi+95. (London: Oxford University Press, 1937.) 6*s*. net.

THE object of this little work, as stated in the preface by the author, who is attached to the department of biology at Guy's Hospital Medical School, is "to enable the student of comparative anatomy to use the text books of human anatomy; and to help the medical student who wishes to improve his knowledge of the anatomy of the brain, or to begin the study of the human brain with a certain background of comparative anatomy".

The book is divided into five chapters, devoted respectively to removal of the brain, its general anatomy, the first dissection in which a general study is made of the cerebral hemispheres, cerebellum and brain stem, the second dissection, and hand sections.

The text is liberally interspersed with diagrams of the human brain as well as that of the sheep, and is provided with a full index.

Disorderly Molecules and Refrigerating Engineering*

THE many facets of the jewel of truth are only too often exposed in a sequence that is bewildering but, even so, it is not often that succeeding facets reflect such dissimilar beams as at first sight to seem to demand the ascription of conflicting virtues to the body of the jewel behind. Sir William Bragg, giving the James Forrest Lecture last year, dealt with the orderly arrangement of the atoms within crystals: Sir Frank Smith, the lecturer for this year, was concerned to demonstrate how the disorderly or random nature of the molecular motions within a substance make it possible for chemical actions on one hand, and the refrigeration industry on the other hand, to exist.

Accepting the identity of the motion of molecules with heat and the corollary that the temperature of a body is a measure of the intensity of their translatory movement, Sir Frank pointed out, in illustration, that if at a given moment the molecules in the air in the lecture theatre were all to be in simultaneous collision with each other, the temperature of the air would drop to absolute zero. Incidentally, under the influence of the gravitational pull, they would fall to the floor. With his assertion that the attainment of very low temperatures has been one of the great scientific advances in recent years, few—and certainly no engineer—would disagree: the knowledge gained of the motion of liquid molecules and of the evaporation of liquids has found widespread application at more elevated temperatures in many fields, of which refrigerating engineering in particular is the obvious example.

Sir Frank Smith purposely refrained from embarking on a historical résumé of low-temperature work, and from employing a mathematical treatment or the empiricisms of Boyle's Law or its various refinements to explain the phenomena he was considering. Instead, he tried to make his approach solely from considerations of the general nature of atoms and molecules, their movements and their interactions. Assuming only that atoms consist of charged nuclei surrounded by electron shells, he proceeded to consider in general terms what might be expected to happen in a collision between two similar atoms. The collision would inevitably set up some, probably electromagnetic, stress and if the collision were such that, for a moment of time, both were brought to a standstill, then the kinetic energies of each of the atoms would disappear and the electromagnetic stresses would simultaneously reach their maximum values. Afterwards, the stressed systems would cause repulsion to take place and the atoms would then move away from one another. However, in addition to this force of repulsion effective at distances comparable with molecular diameters, there is a general force of attraction between atoms and molecules which he suggested might be of the nature of electromagnetic induction. These forces and their resultant were shown graphically, plotting nuclear distances against the force exerted, and it was shown that the curve embraces the solid, liquid and gaseous states and that it indicates that increase in the temperature of a substance will cause expansion. The slope of the curve at zero force is a measure of the elasticity of the material, and the maximum value of the 'resultant' force indicates the maximum force which can be applied without rupture to the substance in the solid form. The value of the nuclear distance at this point represents the ideal elastic limit of the substance; but, in practice, factors introduced by the presence of impurities or other causes modify the attainable elastic limit and rupturing force.

Attention was then directed to a consideration of the Joule-Thomson effect. In every gas there are two effects on expansion, one tending to lower and the other to raise the temperature. The cooling effect depends on the degree of separation of the molecules, and the heating effect depends on molecular collisions, increasing with increase of temperature. At sufficiently high temperatures the net effect is to produce a rise in temperature, at the inversion point there is no change and below it there is a fall in temperature on expansion. Liquefaction of air by compression alone is impossible at ordinary temperatures, and preliminary cooling to below the critical temperature is necessary, although by the use of a cold regenerator or heat-exchanger the need for very high pressures and very low initial temperatures is made unnecessary.

After a brief explanation of the Claude expansion method of refrigeration, Sir Frank Smith passed to the production of relatively pure atmospheric gases by rectification (or the separation of the various constituents of liquid air by making use of their different boiling points) and indicated various commercial uses of the gases so obtained. The same method is applied to water gas and coke-oven gas and can be, and sometimes is, used commercially to produce relatively pure hydrogen.

---

* Account of the James Forrest Lecture delivered by Sir Frank Smith, K.C.B., F.R.S., before the Institution of Civil Engineers on May 3.

These methods have been used under suitable conditions to attain temperatures less than 1° K., but, while it is admitted that it is most improbable that the absolute zero of temperature will ever be reached, advantage has been taken of the magnetic properties of matter to approach it very closely. The phenomena we know as magnetism are due to the existence of atomic magnetic dipoles which, in a magnetic field, are pulled in the direction of that field. The motion of the atoms which is associated with heat resists this pull, and so the resultant magnetic field depends on the temperature as well as on the intensity of the applied magnetic field: the higher the temperature, the less the magnetization. In general, the magnetic dipoles become arranged in orderly fashion at comparatively high temperatures, but there are a few substances, such as iron ammonium alum, in which random orientation still exists at very low temperatures. When such substances are at the lowest temperature attainable by the methods already described, application of a magnetic field modifies the dipole directions and heat is developed. This heat is slowly absorbed by the cold surrounding surfaces, and when the original low temperature has been restored the magnetic field is removed. The dipoles then tend to revert to their previous random orientation and, in so doing, absorb heat, so that the temperature drops. By making use of this effect, a temperature as low as 0·003° K. has been reached.

Turning back from very low temperatures, a pause was made to consider in some detail the mechanism of the evaporation of liquids. Maxwell's law of distribution shows that at any time some molecules are moving with a velocity ten or twenty times greater than that of others. Such fast-moving molecules are the ones which escape from a liquid, and in so doing they tend to lower the average velocity, and hence the temperature, of the remainder. Equally, it is the fast-moving molecules of vapour which tend to re-enter the liquid and increase the average velocity of the molecules there. This counter-effect produces a heating of the liquid. The actual temperature of the liquid will thus be determined by an algebraic summation of these two effects and in order, on balance, to produce cooling it is necessary to eliminate the 'counter-effect' by removing the molecules of vapour as soon as they leave the liquid. By this device, quite low temperatures may be attained.

This effect is the basis of most modern commercial refrigeration machines. Even a century ago, Faraday reached a temperature of 160° K. by evaporating a liquid under an air-pump and to-day, by using helium, a temperature of 1° K. may be attained. Present refrigerating practice utilizes substances (principally ammonia and carbon dioxide) which are vapours at ordinary temperatures and pressures and can be liquefied by subjection to increase of pressure but without preliminary cooling: atmospheric temperature is well below their critical temperatures. It is necessary, therefore, that any pumping mechanism should not only exhaust the vapours from the upper surface of the liquid but should also be able to compress them. When compressed, the gas molecules are brought closer together and the heat produced is extracted by cold water surrounding the compression chamber. The attractive force between the gas molecules becomes greater and greater as the pressure is increased and eventually the substance liquefies. This cold liquid is passed through an expansion- or throttling-valve, and at the same time the pressure to which the liquid is subjected on emergence from the valve is so reduced by suction that the liquid boils. Brine which is circulating around this chamber is therefore cooled and then passes through pipes and tanks as may be desired. It is part of the process to collect the vapours removed from the expansion chamber and to recompress them so that they undergo a continuous process of compression and expansion, liquefaction and evaporization.

Refrigeration engineering now finds application not only to the production of ice and, extensively, to the transport and storage of food of many kinds, but also to the cold storage of bulbs, the conditioning of air for public rooms, cold depositories for furs, carpets and many textile goods, the production of ice in skating-rinks and the freezing of ground for shaft-sinking and tunnelling in water-logged strata.

Whereas, sixty years ago, there was no refrigerating machine and certainly no cold storage provided in ships, to-day the refrigerated space in ships bringing food to Great Britain alone amounts to not less than 100 million cubic feet, equivalent—as it was rather strikingly put—to a single cold store as wide as Victoria Street, London, 20 feet high and 13 miles long. No fewer than thirty countries contribute to our food supply by the help of refrigeration, and it may truly be said that our food can now be practically independent of the seasons.

In very low temperature work, however, progress has not been so rapid, and Sir Frank Smith confessed to a hope that engineers might be persuaded to take an active interest in the problems involved, and commended to his audience the work in progress in the laboratories at both Oxford and Cambridge.

H. W.

Some Aspects of Chemical Kinetics in Gaseous Reactions*

By Dr. H. W. Melville

SINCE the realization, half a century ago, that free energy furnishes an exact criterion for the direction in which chemical changes occur, the control of such processes to the desired end-point is easily accomplished. Indeed this is one of the main functions of chemical thermodynamics. That knowledge, however, provides absolutely no information about the nature and speed of the interactions between molecules. Moreover, in view of the fact that the control of reaction rate is not less important than the production of the specified products, an understanding of the mechanism of reaction is an essential complement to a knowledge of free energy change.

Although chemical kinetics and thermodynamics both came into being practically simultaneously, the latter science soon forged ahead. The reason is not far to seek. Most reactions were studied in the liquid phase, in spite of the fact that there was and still is no satisfactory kinetic theory of liquids. But when an intensive study of gas reactions was commenced about ten years ago, aided by the kinetic theory of gases, material progress soon became evident. Although the subject is still in active state of development[1], it would appear that the broad principles are now firmly established.

No matter how complicated a gaseous reaction may be, it consists essentially of a very few collision processes. For purposes of classification four such processes may be distinguished, namely, unimolecular, bimolecular, trimolecular reactions and collisions in which there is a specific transfer of large amounts of energy between dissimilar molecules. The relationship between the absolute velocity of these reactions and the energy changes involved is now sufficiently well understood to enable predictions to be made regarding new reactions falling into one of the several classes. Thus by suitably altering the conditions under which the reaction takes place, it is possible to isolate and identify the elementary processes, so that some conclusions may be drawn about the chemical constitution of the entities taking part. The greater volume of current work in kinetics is directed towards this goal, thereby making the subject extensive. Only a few of the more recent developments can be mentioned in this article.

One of the most important developments is the use of isotopes of the common elements in tackling certain problems unassailable by conventional methods. For example, if phosphine is irradiated with ultra-violet light, only one molecule is decomposed for every two quanta absorbed, although the absorption spectrum of the molecule indicates that each quantum on absorption dissociates the molecule thus: $PH_3 \rightarrow PH_2 + H$. It was suspected that the recombination $PH_2 + H \rightarrow PH_3$ was responsible for the low quantum yield. This was at once proved[2] by adding deuterium to the phosphine, when deuterium atoms are produced by the reaction $H + D_2 \rightarrow HD + D$, followed by $D + PH_2 \rightarrow PH_2D$, the phosphine thus becoming 'heavy'. The question then arises about the fate of the PH_2 radical. It may decompose to a P atom and an H_2 molecule or it may interact with another of its kind, thus $H_2P + PH_2 \rightarrow P_2 + 2H_2$. If a mixture of PH_3 and PD_3 is decomposed, H_2 and D_2 molecules will be produced in the first mechanism, whereas in the second H_2, HD and D_2 molecules will appear. In point of fact HD molecules are present in their equilibrium amount in the hydrogen gas. Similar experiments give a clue to the mechanism of the photodecomposition of ammonia.

Likewise the possibility of following exchange reactions, such as the rate of formation of HD molecules from $H_2 - D_2$ mixtures or the rate of conversion of para to normal hydrogen, provides important evidence about the nature of the rate-determining step in heterogeneous reactions involving hydrogenation and dehydrogenation. For example[3], in the hydrogenation of ethylene to ethane on a nickel catalyst, a purely kinetic analysis cannot provide any indication whether the dissociation of hydrogen is the rate-determining step. Actually, in absence of ethylene the hydrogen is dissociated far faster than the ethylene is hydrogenated, whereas in presence of ethylene at temperatures around 100° C., dissociation is inhibited altogether. In other words, the hydrogen probably gains access to those parts of the nickel surface not covered with ethylene, is dissociated there and immediately hydrogenates the ethylene. At higher temperatures, the surface becomes denuded of ethylene, when dissociation of hydrogen proceeds more quickly than hydrogenation, owing to the fact that hydrogen atoms then have an opportunity of recombining and so returning to the gas phase. Again, in the exchange reaction, $D_2 + CH_4 \rightarrow CH_3D + HD$[4], a similar technique showed that the dissociation of hydrogen was not the rate-determining step. The following alternatives are open: (*a*) the reaction of a D atom with a methane molecule adsorbed as such, $D + CH_4(ads.) \rightarrow CH_3D + H$, or (*b*) the dissociation of methane followed by the reaction $CH_3 + D \rightarrow CH_3D$. The decision in favour of the second alternative was reached by measuring the rate of interaction of CH_4 and CD_4 molecules to give methanes of intermediate D-content, CH_3D, CH_2D_2, CHD_3, when it was found that the latter reaction went at approximately the same speed as the exchange reaction.

---

*Substance of a series of afternoon lectures delivered at the Royal Institution on February 17 and 24 and March 8.

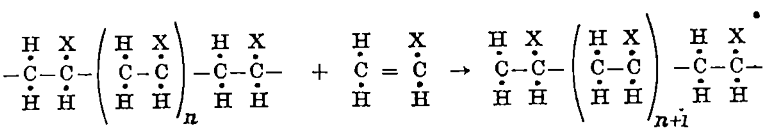
The homogeneous exchange reactions of deuterium atoms with hydrides have also brought under discussion a number of points regarding interactions in simple systems. Here there are two possibilities: (*a*) a simple exchange reaction, $D + HX \rightarrow DX + H$ or (*b*) a dehydrogenation reaction $D + HX \rightarrow HD + X$. Examples of both types are known and appear to fall into a general classification[5]. The simple hydrides of the fourth group are all dehydrogenated, namely, CH_4, SiH_4, GeH_4, whereas NH_3, PH_3, OH_2 and probably ClH exchange atoms without dehydrogenation. With the more complicated hydrides such as C_2H_6, Si_2H_6, N_2H_4, decomposition to simpler fragments CH_4, NH_3 appears to be the general rule. Recent theories[1] of reaction rates have shown that the activation energy required is controlled by the dissociation energies of reactants and products, the internuclear distances, the anharmonic constants of the molecular vibrations and the ratio of Coulombic to exchange forces between the atoms. Hence it is extremely difficult even to predict whether exchange or dehydrogenation will take place in any given instance. The behaviour of CH_4 on one hand and NH_3 on the other might, however, be accounted for in the following way. NH_3 may form a complex NH_3D, such as is supposed to exist in ammonium amalgam. This complex, although of transitory existence, as is known from the fact that ammonia has no influence in reducing the stationary concentration of atomic hydrogen, afterwards decomposes, when any one of the four bonds may break. With methane there is no possibility of forming such a complex; hence if the deuterium atom is to react at all, it can only do so by abstracting a hydrogen atom from the molecule.

It is to be emphasized that the activation energies of the exchange reactions range from about 7 to 14 k.cal., whereas the energy required to sever a hydrogen bond in the hydride is of the order of 100 k.cal. The difference in the two values must be ascribed to what has been termed 'driving force' in chemical reactions[6]. Consider the simple interchange $D + XH \rightarrow DX + H$, then the maximum possible activation energy, that is, the potential energy which the system has to acquire, is the energy dissociation of HX. When a D atom is pushed up towards HX, repulsive forces come into play while there is a simultaneous increase in nuclear separation of HX. On continuing the process, however, a stage or transition state is reached when the attraction between X and D is equal to that between X and H. The system may then revert to its original or final state without having to acquire further potential energy. The rate of this latter process, multiplied by the number of systems in the transition state, determines the rate of reaction. Although the state is essentially one of unstable equilibrium, many attempts[1] have recently been made to compute by the methods of statistical mechanics the concentration of systems in this state. While the results are often roughly in quantitative agreement with experimental measurements, it seems that, owing to lack of precise data, the method is not more accurate than that of the classical collision theory of reactions. What it does provide, however, is a picture of the more intimate details of a chemically effective collision—a process necessarily neglected by the older theory.

Another important outcome of the study of isotopic reactions is the estimation of the part played by the half quantum of residual vibrational energy postulated by quantum theory. All reactions of deuterides are slower than the corresponding changes with hydrides, owing mainly to the lower energy of activation of the latter reaction[5]. Since the vibrations of such molecules are not appreciably excited at reaction temperatures—20°–600° C.—the vibrational energy of molecules consists only of residual energy. In deuterides the vibration frequency is lower than that in hydrides, hence the residual energy is lower. Consequently, in order that the system should reach the transition state, a larger energy is required for the deuterium reaction with a corresponding decrease in reaction velocity. Again, theory and experiment are in qualitative agreement, although an increase in accuracy on both sides is to be desired.

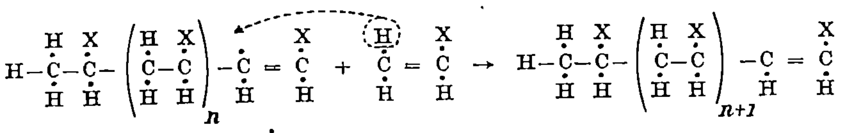
On the more strictly classical side, methods of reaction kinetics are being applied to study polymerization reactions in the gas phase. Suitable examples are difficult to find. In fact there are scarcely any true thermal gas polymerizations known, and it is consequently necessary to start the reaction catalytically or photochemically. At present the latter method is the more useful and has been employed in investigating the mode of growth of polymers from ethylene derivatives The conditions under which polymerization occurs are well defined. Ethylene and all monosubstituted ethylenes of the general formula $CH_2 = CHX$, where X may be halogen, C_6H_5, CN,

$COOCH_3$, etc., polymerize. Likewise, disubstituted derivatives $CH_2 = CXY$, where X is similar to or identical with Y also aggregate readily, but if X or Y is transferred to the other carbon atom, thus $CHX = CHY$, polymerization is completely prevented. For example, methyl methacrylate $CH_2 = C.(CH)_3COOCH_3$ readily polymerizes; methyl crotonate refuses to do so[7]. The precise explanation of these facts has not yet been discovered. When polymerization is initiated photochemically, the radiation invariably enters the molecule by the X or the Y group and thereby renders the double bond reactive. If a short enough wave-length is employed—around 2000 A.—where the double bond itself exhibits absorption, then the energy of the quantum is so big that the molecule is often broken up and very little polymerization can be detected. The nature of the initiation process also raises the question of the mechanism of growth. In view of the fact that one quantum will polymerize, in some instances, a thousand molecules of monomer, it is evident that, once a molecule is activated, monomer molecules add on comparatively readily. The question which arises is whether the growth occurs through (*a*) the intermediacy of a free radical, or (*b*) by the so-called double bond mechanism.



$$-\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}-\left(\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}\right)_n-\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}- \;+\; \overset{H}{\underset{H}{C}}=\overset{X}{\underset{H}{C}} \rightarrow \overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}-\left(\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}\right)_{n+1}-\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}-$$

(*a*)

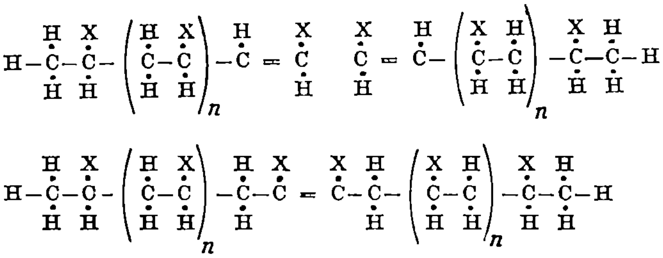


$$H-\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}-\left(\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}\right)_n-\underset{H}{C}=\overset{X}{\underset{H}{C}} \;+\; \overset{H}{\underset{H}{C}}=\overset{X}{\underset{H}{C}} \rightarrow H-\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}-\left(\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}\right)_{n+1}-\underset{H}{C}=\overset{X}{\underset{H}{C}}$$

(*b*)

A method of discriminating between the two mechanisms is by intentionally making a free radical by generating, photochemically, H atoms or methyl radicals. These react with the monomer to form $CH_3-\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}-$. With some molecules, for example, methyl methacrylate, $CH_2 = C.(CH)_3.COOCH_3$, the normal photopolymerization and the radical-induced polymerization have quite different characteristics. In the radical polymerization, the reaction occurs wholly in the gas at a rate proportional to the square root of the intensity of the light and is completed within 10^{-3} sec. when two growing polymers come into collision. On the other hand, in the normal reaction the polymerization certainly starts in the gas phase but continues on the walls of the reaction vessel, when the light is switched off, for hours and even days. The maximum dark rate is proportional to the area of the vessel illuminated and is independent of the intensity of illumination. There can therefore be no doubt that the normal growth occurs by the double bond mechanism.

This does not explain why the molecule keeps on growing indefinitely. An explanation for the reason of this behaviour is obtained when methyl acrylate is examined. This polymer does not grow indefinitely. It dies soon after polymerization has proceeded to some considerable extent in the gas phase. Its death is due to a collision between two growing polymers thus:



$$H-\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}-\left(\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}\right)_n-\overset{H}{C}=\overset{X}{\underset{H}{C}} \quad \overset{X}{\underset{H}{C}}=\overset{H}{C}-\left(\overset{X}{\underset{H}{C}}-\overset{H}{\underset{H}{C}}\right)_n-\overset{X}{\underset{H}{C}}-\overset{H}{\underset{H}{C}}-H$$

$$H-\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}-\left(\overset{H}{\underset{H}{C}}-\overset{X}{\underset{H}{C}}\right)_n-\overset{H}{\underset{H}{C}}-\overset{X}{C}=\overset{X}{C}-\overset{H}{\underset{H}{C}}-\left(\overset{X}{\underset{H}{C}}-\overset{H}{\underset{H}{C}}\right)_n-\overset{X}{\underset{H}{C}}-\overset{H}{\underset{H}{C}}-H$$

involving the simultaneous migration of two hydrogen atoms. If two methacrylate polymers were to interact in this way, two methyl groups would have to migrate—a rather improbable process. The long life of the methacrylate polymers is apparently due to the immobility of a methyl group. The methacrylate polymer can, however, be stopped growing by hydrogenating the end of the molecule by atomic hydrogen.

Kinetic methods also permit of the determination of the molecular weight of a polymer produced photochemically. The obvious method of computing the molecular weight by multiplying the number of molecules polymerized per quantum absorbed by the molecular weight of the monomer is based on the unjustifiable assumption that each quantum absorbed starts off a chain. A more satisfactory method consists in discovering a suitable inhibitor, one molecule of which (in the inhibited photo-reaction) adds on to each chain started, thereby stopping growth. The ratio of molecules polymerized to molecules of inhibitor consumed then gives the chain length of the inhibited and therefore that of the normal reaction Butadiene has been used in this way for methyl acrylate polymers.

The question of the estimation of the cross-linking of polymer chains is still an outstanding problem in this branch of the subject, as the method hitherto available for computing branching in ordinary explosive chain reactions is not applicable in the present instance.

The Spring Drought in the British Isles

By E. G. Bilham

THE spring of 1938 has been rendered memorable in the British Isles by a remarkable sequence of meteorological events, the results of which have been disastrous to the horticultural and farming sections of the community. The main purpose of this article is to furnish data in regard to the drought, but it is important to realize that the deficiency of rain, unprecedented as it has been, is only one aspect of a singularly unfavourable meteorological complex. Thus the fruit growers would probably have made little complaint about the drought if they had been spared the frosts of April and early May, following upon an exceptionally mild March in which all vegetation made rapid growth. Incidentally, March and April have provided an example of the untrustworthiness of the generalization that the rainfall of the British Isles is related to the direction of the prevailing wind; in March we had a great shortage of rainfall and the winds were persistently south-westerly; in April we also had a very dry month and the winds were persistently north-easterly.

The period of exceptional rainfall deficiency began in February, following upon a wet January. In February pressure exceeded the normal by about ten millibars in all parts of the British Isles, and as is usual when anticyclonic conditions predominate, rainfall was markedly below normal, though there was an excess in the west and north-west of Scotland, and in small areas in Yorkshire and south-west Ireland. At Kew Observatory the total fall for the month was only 0·31 inch, or 20 per cent of the normal. The general fall over England and Wales, deduced from the observations at a selection of representative stations, was 1·34 inches, or 52 per cent of the normal. For Scotland, the percentage was 80, for Ireland 66, and for the British Isles as a whole, 62.

The corresponding values for March and April, and for the whole period February to April, are included in the accompanying table. It will be seen that March was very decidedly drier than February in England and Wales, though Scotland had nearly the normal rainfall. The drought was particularly severe in the western Midlands, and at Ross-on-Wye the total for the month was no more than 0·02 inch, the smallest total for March in records going back to 1859. On the other hand, exceptionally heavy rains occurred in parts of western Scotland. At Loan (Loch Quoich), in Inverness-shire, the total for March was no less than 50·03 inches, one of the largest monthly totals ever recorded anywhere in the British Isles.

GENERAL RAINFALL OF THE BRITISH ISLES, FEBRUARY TO APRIL, 1938

	England and Wales	Scotland	Ireland	British Isles
February Per cent of normal	1·34 in. 52	3·34 in. 80	2·33 in. 66	2·02 in 62
March Per cent of normal	0·72 in. 27	3·93 in. 97	2·18 in. 65	1·67 in 52
April Per cent of normal	0·28 in 13	1·02 in. 34	0·20 in. 7	0·43 in. 17
Total Per cent of normal	2·34 in. 32	8·29 in. 74	4·71 in 49	4·12 in. 45

Although the total fall for February and March was exceptionally small in many areas, the drought had not achieved a record-breaking character at that stage. For England and Wales, the general fall in the two months was 2·06 inches, and we only have to go back ten years to 1929 to find a substantially smaller fall, 1·60 inch, in the same two months. April, however, brought a very great and general intensification of the shortage. With a general fall of no more than 0·43 inch over the British Isles as a whole, it was not only the driest April in our annals, but also the driest month of any name of which we possess records. The general rainfall was, however, only slightly exceeded in February 1891, June 1925 and February 1932.

For England and Wales the percentage of normal was 13. So far as our information goes, only three previous Aprils have yielded percentages less than twenty; namely, those of 1817 (16 per cent), 1893 (18 per cent) and 1912 (15 per cent). April 1893 was remarkable for having yielded no rainfall at all over a large area in south-east England. April 1938 achieved that distinction at only a few stations; the main feature was the widespread distribution of the drought. The very small percentage of normal, 7, in Ireland is particularly striking. No previous April has produced anything like such a deficiency in that area.

The total rainfall of the three months February to April 1938 amounted in England and Wales to 2·34 inches, or 32 per cent of the normal. No previous combination of three successive months has yielded so small a total since comparable evaluations began in the year 1870. It is possible to carry the comparison back for more than another century, with some approach to certainty, by referring to a series of estimates of general rainfall percentages by Dr. J. Glasspoole and Miss F. J. Nicholas published in *British Rainfall*, 1931. From these estimates it appears that a comparable period occurred in 1785, when the combined total for February to April amounted to about 2·1 inches. No more recent sequence of three months has been drier than that experienced this year.

To the natural question "why?", we can only reply at the moment that the dry weather was due to an exceptional persistence of anticyclonic conditions, combined in April with a prevalence of north-easterly winds. At the present stage of our knowledge of the causes of seasonal weather changes, the reasons for such persistence cannot be clearly made out; still less can they be foreseen. It has long been realized that the investigation of such problems demands a study of meteorology on a world-wide scale, and we may recall that the exceptional summer of 1911 provided the initial incentive which led to the regular publication of the collection of world weather statistics known by the name of the *Réseau Mondial*. If the harvest has not yet been garnered, we may, however, derive some satisfaction from the fact that there are many workers in the field, and also from the fact that some degree of success has rewarded the essays in 'seasonal foreshadowing' made in India and elsewhere.

Obituary Notices

Mr. J. E. Marsh, F.R.S.*

THE numerous friends and old students of James Ernest Marsh will have learned with regret of his death on April 13 at the age of seventy-seven years. He was one of the few remaining chemists whose most active period of work belongs to last century, having been University demonstrator in chemistry at Oxford from 1886. In my undergraduate days, 1896–98, Marsh in organic chemistry and V. H. Veley, who died at just the same age in 1933, in inorganic chemistry, were almost the only ones in Oxford keeping the flag flying as regards original work in the subject.

Marsh's influence on me started, indeed, at school, under R. E. Hughes, science master at Eastbourne College, who, whilst at Jesus College, had worked with Marsh, and was still being provided by him with materials and help in its continuation. Few schoolboys certainly can have prepared camphoryl chloride. But I still have a vivid recollection of carrying out this preparation on a large scale in the open playing field, adjoining the school laboratory, from camphoric acid and phosphorus pentachloride, and of the traditional 'torrents' of hydrochloric acid gas evolved. That, to a schoolboy, was the joyous beginning of a lifetime admiration.

At that time Marsh was deeply immersed in the study of camphor and the related group of terpenes. The problem of the constitution and synthesis of camphor was then very much to the fore, and some of the most eminent chemists, including the late Prof. W. H. Perkin, were engaged on it. In conjunction with his students, notably J. A. Gardner and A. Hartridge, Marsh published about twenty important papers in this field between 1889 and 1910, in the first of which he had suggested for camphor a highly original structural formula. Although this was ultimately disproved in favour of one propounded by Bredt in 1893, he made, in the course of the work, many interesting and important discoveries. The stereochemistry of this group led to great advances in our knowledge of that subject, and Marsh himself was the first to obtain, for the case of camphoric acid, *optically active* stereo-isomers of the *cis* and *trans* variety associated with the ring structure.

At this time Marsh was an acknowledged leading authority in the field of stereochemistry, and his lectures on the subject, drawing his illustrations and examples from this field, and many others such as the sugars, then undergoing intensive study, were most inspiring and threw an interesting light over the whole field of organic chemistry. Another topic on which he used to lecture regularly was the history of chemistry. In 1929 he collected in a book entitled "The Origins and the Growth of Chemical Science" his main conclusions, the chief of which was that the earlier work on salt formation and the fixation of gases by the British chemists, Boyle and Black, were the real beginning of the subject as a science rather than the later work of Lavoisier on combustion to which it is often ascribed.

In later years, largely with R. de J. F. Struthers, Marsh worked much on the numerous curious and interesting complexes formed by certain compounds of mercury with organic solvents and radicals, now ascribed, in the modern theory of valency, to the unique character of mercury among the metals and its power of forming covalent linkages of unusual type.

* Reprinted by permission of the editor, from the *Oxford Magazine*.

Another subject that attracted Marsh was the preservation of stone from decay, and in 1926 he wrote a highly original little monograph on the subject entitled "Stone Decay and its Preservation". Finding in decayed stone from diverse localities the presence of nitrates, he concluded that the decay was due to forms of life in the stone, such as the micro-organisms known to exist in it. The treatment to preserve it should aim at sterilizing it and keeping it sterile. The book concludes : "All that is recommended is to keep the walls of a building clean and thus prevent them from becoming nests of living organisms". In the last conversation I had with him, he discussed the chemistry of taste and was then working upon it.

Marsh was educated at Rugby and Balliol, studied also both in Germany and Paris, and for a short time was lecturer in materia medica in Oxford. He was made a fellow of the Royal Society in 1906, and served on the council of the Chemical Society in 1902–7. He was married in 1903 and leaves a widow and five daughters. In 1906, when forty-six years old, he astonished everyone by winning by examination an open prize fellowship at Merton College, which he held up to 1930, and during it filled for a time the office of sub-warden.

In his younger days Marsh was an intrepid yachtsman, and in company with one of the three Lynam brothers used to take long voyages in their small yacht among the Hebrides and even out into the open Atlantic. Inquiring for him in 1901 at Oban, knowing his intention of attending the British Association meeting at Glasgow that year, I found the local waterman in considerable anxiety, as nothing had been heard of the yacht or its crew for many weeks. He loved the Scotch crofters and liked to get right away among them and to share their mode of life. Though to unsympathetic people he may not have troubled much to make himself agreeable, he was essentially very human and lovable, and those who worked with him and were admitted to his friendship will cherish his memory with deep affection and loyalty. FREDERICK SODDY.

Captain R. S. Rattray, C.B.E.

We record with deep regret the death of Captain R. S. Rattray, distinguished as an anthropologist and authority on the native peoples of West Africa, who was killed in an accident while gliding at Farmoor, near Oxford, on May 14, at the age of fifty-six years. Captain Rattray was acting as pilot of the Oxford University and City Gliding Club, which he himself had founded only a week before.

Robert Sutherland Rattray was son of the late Mr. A. Rattray of the Indian Civil Service, and grandson of the late Robert Haldane Rattray, Chief Justice of Bengal. He was educated at Stirling High School and Exeter College, Oxford, holding the diploma of his University in anthropology, and the degree of D.Sc. He was *Officier d'Académie* of France, and was called to the Bar by Gray's Inn in 1914. In the South African War he served as a trooper, receiving the Queen's medal with five clasps. In 1902 he entered the service of the African Lakes Corporation, British Central Africa, serving until 1907, when he entered the Colonial Civil Service on the Gold Coast. He became an assistant district commissioner in 1911, and thereafter held various administrative appointments, until in 1920 he was acting senior assistant Colonial Secretary and clerk to the Legislative Council. During the Great War he served in Togoland, being district political officer during the Anglo-French occupation in 1914–17. For his services he received the M.B.E. and was advanced to C.B.E. in 1929.

In 1924 Rattray was made head of the recently formed Anthropological Department in Ashanti. It is in connexion with Ashanti that Rattray's name will longest be remembered. He had already made some notable contributions to the study of the customs and folk-lore of West Africa, when soon after his appointment as Government anthropologist he published his "Ashanti" (1924). This was the first of a series of volumes, in which he made a comprehensive and detailed study of Ashanti social organization and law, art and religion. Much interest was aroused by his unravelling of the story of the Golden Stool of the rulers of Ashanti, which, long familiar to the British public, had been a mystery completely misunderstood, even by many whose position demanded more accurate information. This matter was certainly not without interest—great interest indeed—for the anthropologist, but the overwhelming value of Rattray's studies for his fellow workers lay in his accurate observation, his clear, precise statement, and his restrained, but illuminating, power of interpreting his facts in relation to their cultural environment. To a wider public, the volume containing his study of Ashanti art is made a standard work of reference by the inclusion of a contribution from Vernon Blake discussing the place of African art in relation to the principles of æsthetics.

One of Rattray's duties not long before his retirement was to make a survey of tribes of the hinterland brought under British control by mandate, but as little known to anthropological science as they were to the administration. This survey was made with a view to the introduction of some measure of indirect rule ; and a record of the observations then made was published by him in his book "The Tribes of the Ashanti Hinterland" (1932). Its essential completeness, when considered in relation to the rapidity with which the work had to be carried through, is a lasting memorial of Rattray's quickness of observation and grasp of detail. On his retirement Rattray was a frequent lecturer on anthropological topics at Oxford and elsewhere ; and it may be noted that he was then one of the first to point out that indirect rule is not a complete panacea for the difficulties of native rule, not the least of these,

Reversibility of the Equations of Classical Dynamics

IN a recent series of papers, one of us has derived the equation of motion[1] of a free particle in the presence of the expanding universe by *a priori* methods, and constructed an associated dynamics. The observers' clocks were supposed so graduated[2] that the expansion appeared *uniform*, and the resulting scale of time was called the t-scale. But the equations of motion reduced to their classical form[3] only if observers' clocks were regraduated from t to τ where

$$\tau = t_0 \log (t/t_0) + t_0,$$

and all derived measures correspondingly changed. Accordingly, the 'uniform time' of mechanics was identified as τ-time. In this measure of time, the universe appears as a stationary, non-expanding system, and the red-shift is shown[4] to be attributable to an acceleration of atomic absorption- or emission-frequency with time in τ-measure, so that the light, emitted long ago by a distant nebula, appears relatively displaced to the red. In a joint paper about to appear in *Zeitschrift für Astrophysik*, we have analysed generally all monotonic graduations of our temporal experience, that is, all possible modes of clock-graduation, and shown that of these there is just one, τ-measure, which reduces the members of any 'linear equivalence' to relative rest. This again we have identified as the time of mechanics.

The object of the present communication is to point out that this identification can be at once confirmed from Mach's principle and the well-known fact of the reversibility of the classical mechanical equations—the fact that they are unaltered in form on replacing $d\tau$ by $-d\tau$. For, by Mach's principle, the equations of motion of a free particle express the relation of the particle-in-motion to the general distribution of matter and motion in the universe. Suppose we reverse the velocity of a free particle. Then it can only reverse its trajectory if the motion of all the other particles in the universe is reversed at the same time, and this will not actually occur unless these other particles are on the whole relatively *stationary*, when the reversal of *their* relative motion makes no difference. Accordingly, the equations of motion of a free particle may be expected to be unaltered in form on reversing the differential of time only when the scale of clock-graduation is so chosen that the fundamental particles appear as relatively stationary. Since the equations used in ordinary mechanics *are* unaltered in form by this transformation, it follows that the scale of clock-graduation they imply is the τ-scale, namely, that for which the universe is stationary, that is, non-expanding. In confirmation, it is at once found that the equations of motion in any other scale, in particular the well-discussed t-scale equation,

$$\frac{dV}{dt} = -(P - Vt)\frac{Y}{X},$$

are altered in form on reversing V and dt.

Since a red-shift is observed to exist, and since the universe is non-expanding in the ordinary mechanical or τ-scale, it follows at once that as regards the emission or absorption of radiation atoms cannot keep the τ-scale. Closer discussion has shown that the frequency of the photon emitted must be constant on the t-scale[5].

These considerations throw a flood of light on what used to be regarded as a grave difficulty: How can the secular increase of entropy be reconciled with the reversibility of the Hamiltonian equations ? It now appears that the reversibility of the Hamiltonian equations is a peculiar property due to the particular choice of the scale of time in which the universe is relatively stationary. In general, for an arbitrary choice of clock-graduations, the dynamical equations are not reversible. Reversibility of equations of motion is therefore to be considered as irrelevant to the onward march of entropy, which simply expresses the tendency towards a state of greater probability independent of the scale of clock-graduation adopted.

Eddington has directed attention[6] to three time-direction sign-posts: (1) our consciousness of the temporal sequence; (2) the expansion of the universe; (3) the increase of entropy. We now see that by suitable choice of clock-graduation the second is abolished and replaced by a statement about the acceleration of 'atomic clocks'. The first is basic and given, and is so used in our analysis. The third is not therefore 'the barb on time's arrow'—time's arrow is already barbed in the statement of the before-and-after relation in the observer's experience; the increase of entropy must therefore be a theorem, or consequence of the existence of the temporal sequence.

It is perhaps scarcely necessary to add that when in the above we use the term "relatively stationary", we are not appealing either to material measuring rods or to the indefinable 'rigid' length-measure. We mean simply that the light-time difference for a to-and-fro signal, measured on the appropriately graduated clock, is a constant.

A New Boundary Condition and the Geodesic Postulate

Einstein and Rosen[1] have admitted that the geodesic postulate is an extraneous one and that the field-equations of gravitation must give both matter and motion independently of such a postulate. It has not been rigorously proved yet that the geodesic postulate is implicit in the field-equations[2]. A new boundary condition is stated here, couched in invariant terms; it is found to be satisfied by the Schwarzschild solution, and the content of the geodesic postulate that a test-particle describes a geodesic is shown to be implied by this condition. No extraneous postulate is necessary to account for the motion if the new boundary condition is accepted.

The inner and outer fields of an isolated spherical mass are given by the line-elements,

$$ds^2 = -\sec^2 x\, dr^2 - r^2(d\theta^2 + \sin^2\theta\, d\varphi^2) + (A - B\cos x)^2 dt^2, \quad . \quad . \quad . \quad (1)$$

where $R \sin x = r$ and

$$ds^2 = -\left(1 - \frac{2m}{r} - \frac{\lambda r^2}{3}\right)^{-1} dr^2 - r^2(d\theta^2 + \sin^2\theta\, d\varphi^2) + \left(1 - \frac{2m}{r} - \frac{\lambda r^2}{3}\right) dt^2 \quad . \quad . \quad . \quad (2)$$

The boundary conditions that are satisfied at the common surface, $r = r_0$, are two, as usually stated: (i) the pressure $p = 0$ and (ii) $g_{\mu\nu} = g'_{\mu\nu}$, the dash indicating the external field. The boundary conditions in the corresponding problem of Newtonian gravitation suggest that there is one more condition satisfied by (1) and (2) at $r = r_0$; and that is found to be that the laws of mechanics, namely,

$$(T^{\nu}_{\mu})_{\nu} = 0, \qquad (3)$$

hold good whether we use the three-index symbols for $g_{\mu\nu}$ or for $g'_{\mu\nu}$ at the common surface. In other words, this boundary condition is $(T^{\nu}_{\mu})_{\nu} = (T^{\nu}_{\mu})'_{\nu} = 0$. In the one-body problem considered above, this merely demands $\Gamma^{4}_{r4} = \Gamma'^{4}_{r4}$ ($r = 1, 2, 3, 4$), which condition is found to be satisfied at the boundary..

For a perfect fluid for which the condition of continuity holds good in the form $[(p+\rho)v^i]_i = 0$, if, at the boundary, the pressure-gradient is supposed to be negligible compared to the density, (3) reduce to the equations of geodesics[4],

$$(v^{\mu})_{\nu} v^{\nu} = 0. \qquad (4)$$

By the new boundary condition, (4) become geodesics not only of the inner but of the outer field also. Thus at the surface a fluid runs in geodesics of the external field. A particular case of this general result for a finite fluid mass is provided by a test-particle which, if treated as of negligible dimensions, traces a geodesic.

Distortion of Mountain Strata, Isostasy, and Glacial Periods

THE connexion of the distorted mountain strata with isostasy has been examined in NATURE of April 2, p. 603. The foundation of the argument was that the strata were originally deposited horizontally at the bottom of the sea. It is, however, necessary to go further back, for they must have been lifted to a great height before isostatic influences could begin to operate. There is here a problem of flow in a medium of extremely viscous type, namely, the outer region of the earth beneath, which can scarcely be avoided. If anywhere the horizontal drift beneath is from both sides towards the same centre the lighter material above it will be pushed up as is required, and in part also pushed down, but the resulting displacement need not at first be isostatically distributed. So also at ocean deeps the underlying drift away from the centre may carry along the more solid upper strata, thinning them out: anyhow a problem presents itself there. Moreover, in all internal motions the drift relative to the surface is necessarily tangential. The analogy of the sideway shrinking up of a flat roll of cloth has been employed.

The process here described would be remote in time. It can scarcely be going on now to any sensible degree, *unless isostatic conditions prevail*; for it would gradually alter the period of the earth's rotation, which is known for astronomical reasons to have been extremely steady for some thousands of years. This consideration also excludes any hypothesis of great accumulation of ice in the Arctic regions; for it would lower the general level of the oceans and a change of level of more than a few centimetres is not permitted. So too the land must have not altered its *mean* level more than this in historic times. But in times beyond historical record this restriction does not apply. (These considerations favour the Darwin theory of the origin of coral reefs.)

This astronomical limit appears to be fundamental for geophysics. It asserts that change of level of the ocean of one centimetre is not permitted, unless the day was exceptionally longer in the glacial periods : if the water were removed to this depth and piled up uniformly on ice-caps within 5° or 350 miles of the poles, the resulting thickness would be only about 130 cm. or 50 inches, and if within 10° only 12 inches. Within such narrow limits are accumulations of ice now restricted. Sir George Simpson (NATURE, April 2) advances the view that recent ice ages may be due largely to change of temperatures of the Atlantic produced by drift of ice in it down into temperate latitudes ; and here question arises as to the permanent source of supply of the ice. A different mode of origin which has found some favour with the writer is the temporary diversion of ocean currents on a large scale by ice piling up in the narrower parts of their channels and so blocking the flow. Both causes might operate. But the recent glacial period on the central Indian plains appears to be a more intractable proposition.

Maxwell's Equations and the "Flux-Cutting" Principle

IN NATURE of February 5, Dr. C. V. Drysdale attempts a simplification of Maxwell's electrodynamic equations, on the grounds that these in their original form are difficult to comprehend and to apply, and not completely fundamental. As regards the latter criticism, it must be admitted that Maxwell rarely leaves much scope for improvement in his mathematical statements of physical laws, and so far as the complexity is concerned, many years' lecturing experience have convinced me that the average electrical engineering student of pass degree standard finds little difficulty in understanding and appreciating the concise and elegant expression of the laws of induction, which he has had ample opportunity of testing experimentally in his laboratory work, and usually finds the wider applications, to transmission, skin effect, and metallic reflexion, both easy and interesting.

A closer examination of Dr. Drysdale's argument leaves my opinion of Maxwell's achievement unshaken.

The first modification is introduced rather abruptly with the words : "if we write $j\frac{\partial E}{\partial x}$ for curl E in the equation $-$ curl $E = \dot{B}$ . . ." It is not easy to see any justification for this suggestion. It is true that the components of the vector curl E may be obtained by applying the differential operator $\mathbf{i}\frac{\partial}{\partial x} + \mathbf{j}\frac{\partial}{\partial y} + \mathbf{k}\frac{\partial}{\partial z}$ in a vectorial manner to the vector E, where **i**, **j** and **k** are the unit vectors along the axes X, Y and Z, respectively, that is, by developing the determinant $\begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ E_x & E_y & E_z \end{vmatrix}$. But here the scalar products $\mathbf{i}\times\mathbf{i}=\mathbf{j}\times\mathbf{j}=\mathbf{k}\times\mathbf{k}=1$, and the vector products $\mathbf{i}\wedge\mathbf{i}=\mathbf{j}\wedge\mathbf{j}=\mathbf{k}\wedge\mathbf{k}=0$, whereas Dr. Drysdale later asserts that $\mathbf{j}^2= -1$, and thus confuses the unit vector **j** with the electrical engineer's phase rotating operator and tempts the reader to suspect that the relation $E=jVB$ expresses a quadrature phase difference between E and B.

The next step is equally sweeping and illegitimate : it consists in "writing" $\frac{\partial B}{\partial t} = \frac{\partial B}{\partial x}\frac{dx}{dt}$.

It is now obvious, however, that the original equations have been reduced by making some very special assumptions, namely, that $E_x=E_y=0$, and $B_x=B_t=0$, leaving

$$\frac{\partial E_z}{\partial x} = \mu\frac{\partial H_y}{\partial t} \text{ and } \frac{\partial H_y}{\partial x} = \varepsilon\frac{\partial E_z}{\partial t},$$

and by this specialization a set of equations has been obtained which *ipso facto* is less general, that is, less completely fundamental, than the original system.

It is, of course, easy to obtain a simple wave equation from the above two equations, and the solution and discussion would seem fairly simple, but Dr. Drysdale prefers to introduce a magnet which is moved transversely through a non-conducting medium with a velocity V, inducing an E.M.F. $E= -j\mu VH$, this E.M.F. in turn inducing a magnetic force $H^1=\varepsilon\mu V^2H$, etc. It is asserted that thus an electromagnetic wave is generated, though it is not easy to trace any connexion with wave motion in the ordinary sense. It is further pointed out that, as the velocity increases, the fields will increase, unless H is diminished to $H-H^1=(1-\varepsilon\mu V^2)H$, and it is concluded that when $1-\varepsilon\mu V^2=0$, H is also 0. This is tantamount to a statement, that when one factor in a product is 0, the other factor is also 0.

The extension of this argument to the case of semiconductors shows an equal disregard for elementary rules of ordinary, partial and total differentiation and leads to yet another curious equation,

$$\frac{d^2E^1}{dt^2} = V^2\frac{\partial^2E^1}{\partial t^2}.$$

Dr. Drysdale's main contention is that flux-cutting is more fundamentally correct, as an E.M.F. inducing agent, than flux variation, but it is well to remember that when the dynamo designer speaks of a conductor, he is at the moment concentrating his attention on one side only of a complete armature coil—if the other side were not there, his dynamo would scarcely be a success. It is, of course, the flux variation through the armature *coil* which generates the E.M.F. Dr. Drysdale himself admits that, in the case of a transformer, the flux variation principle is correct (and even "more convenient"), and the attempt at saving the flux-cutting principle, by invoking some mysterious and incomprehensible "cutting" by a stationary coil, can scarcely be taken seriously.

Yet Dr. Drysdale claims to have rendered Maxwell's equations more completely fundamental and more intelligible, and urges that his representation "should be adopted". It might well be asked—by whom ? If text-book writers were to adopt this kind of argument, it could only add to the confusion.

J. A. WILCKEN.

13 Welbeck Street,
London, W.1.

No one has a greater admiration for Maxwell's magnificent achievements than I have, and so far from wishing to decry them, my main object has been to help to restore them to their rightful place as the greatest scientific generalization we have seen. But there has been a decided tendency to neglect them of late, and I am convinced that this has been due to the complexity of the mathematical processes associated with Maxwell's equations, which has obscured their simple physical basis and conclusions. Dr. Wilcken is to be congratulated on being able to make them easily intelligible to students, but quite recently a professor of physics at a leading London college told me frankly that he had never been able to understand Maxwell's electromagnetic theory of light, and I have found that considerable confusion exists among all with whom I have discussed it. The simplified treatment has given me a much clearer realization of the physical processes involved and has convinced me that Maxwell's conclusions were entirely sound although his equations were not completely fundamental.

Dr. Wilcken commences by objecting to my "abrupt" substitution of $j\frac{\delta}{\delta x}$ for Maxwell's curl function, and suggests that it was introduced as a quasimathematical device to give colour to a preconceived bias in favour of the flux-cutting principle. I admit and am sorry for the abruptness, but my article was a highly condensed epitome of a long unpublished paper and was intended merely to give an outline of the theory in the shortest possible space. According to my recollection and notes, the inspiration for the modified (apparently I must not say "simplified") equations arose from wrestling with the array of differential equations in Drude's "Theory of Optics"; and becoming tired of the effort I decided on examining the problem of electromagnetic wave propagation from first principles. The most simple way of doing so was to consider a forced electromagnetic disturbance created by moving a magnet with wedge-shaped gap with velocity V in a direction transverse to its magnetic field B and in a plane containing the normals to its plane faces; and it was easy to see that in this case curl $E = \frac{\delta E}{\delta x}$ as regards magnitude and that $\dot{B}\left(=\frac{dB}{dt} = \frac{\delta B}{\delta t} + \frac{\delta B}{\delta x}\frac{dx}{dt} + \frac{\delta B}{\delta y}\frac{dy}{dt} + \frac{\delta B}{\delta z}\frac{dz}{dt}\right) = \frac{\delta B}{\delta x}\frac{dx}{dt} = V\frac{\delta B}{\delta x}$; so that Maxwell's third equation-curl $E = \dot{B}$, becomes $-\frac{\delta E}{\delta x} = V\frac{\delta B}{\delta x}$, or $E = -VB$, if $E = 0$ when $V = 0$. Similar treatment of Maxwell's fourth equation, curl $H = 4\pi\dot{D}$, of course gave $\frac{\delta H}{\delta x} = 4\pi V\frac{\delta D}{\delta x}$, or $H = 4\pi VD = VJ$ if $H = 0$ when $D = 0$, and $J = 4\pi D$. As x disappears in the integration, the equations $E = -VB$ and $H = VJ$ are independent of the direction of propagation.

Up to this point, I had not considered the flux-cutting principle, but the correspondence of the equation $E = -VB$ with the dynamo designer's or flux-cutting formula of course struck me, and as I had long ago come to the conclusion that Faraday's rotating disk experiment showed that the induced E.M.F. was due to the cutting of the magnetic flux, it was apparent immediately that the equation $E = -VB$ was not a mere transformation of Maxwell's third equation but an expression of an independent experimental fact. Similarly Rowland's demonstration that a magnetic field was induced by the rotation of two oppositely charged disks or the cutting of an electrostatic field afforded experimental verification of the formula $H = VJ$. The two equations $E = -VB$ and $H = VJ$ may therefore be regarded simply as direct expressions of the results of Faraday's and Rowland's rotating disk experiments, and my original derivation of them by transformation of the Maxwellian equations, which I quite admit was not general, is of no importance except as showing a connexion between them. The equations $E = -[VB]$ and $H = [VJ]$ are completely general, and I hope to show that they are more fundamental.

As Dr. Wilcken does not like my employment of the quadrantal versor $\mathbf{j} = \sqrt{-1}$ to indicate the directions of the induced forces, on the grounds that it leads to confusion with its use in alternating current theory and with vector analysis, there is no objection to writing the four equations for an isotropic dielectric as $J = \varepsilon E$, $B = \mu H$, $E = VB$, and $H = VJ$, and leaving the directions to be determined by the ordinary rules. I fail to see, however, why students who are familiar with the use of $\mathbf{j}$ for alternating current vectors should be confused by its application to any other vectors.

I dissent entirely from Dr. Wilcken's remarks concerning the flux-cutting principle, but to deal with them and his complete misapprehension of my method of explaining the generation and propagation of an electromagnetic wave would take too much space for a note; and I propose shortly to submit a further article, which I hope will make the flux-cutting principle and its application quite clear and indisputable.

C. V. Drysdale.

Why do we have Winter Heating?

The layman will answer: "To make the room warmer." The student of thermodynamics will perhaps so express it: "To import the lacking (inner, thermal) energy." If so, then the layman's answer is right, the scientist's wrong.

We suppose, to correspond to the actual state of affairs, that the pressure of the air in a room always equals that of the external air. In the usual notation, the (inner, thermal) energy is, per unit mass,

$$u = c_v T.$$

(An additive constant may be neglected.) Then the energy content is, per unit of volume,

$$u^1 = c_v \rho T,$$

or, taking into account the equation of state,

$$p/\rho = RT,$$

we have

$$u^1 = c_v p/R.$$

For air at atmospheric pressure,

$$u^1 = 0 \cdot 0604 \text{ cal. cm}^{-3} = 60 \cdot 4 \text{ Cal. m.}^3$$

The energy content of the room is thus independent of the temperature, solely determined by the state of the barometer. The whole of the energy imported by the heating escapes through the pores of the walls of the room to the outside air.

I fetch a bottle of claret from the cold cellar and put it to be tempered in the warm room. It becomes warmer, but the increased energy content is not borrowed from the air of the room but is brought in from outside.

Then why do we have heating? For the same reason that life on the earth needs the radiation of the sun. But this does not exist on the incident energy, for the latter apart from a negligible amount is re-radiated, just as a man, in spite of continual absorption of nourishment, maintains a constant body-weight. Our conditions of existence require a determinate degree of temperature, and for the maintenance of this there is needed not addition of energy but addition of entropy.

As a student, I read with advantage a small book by F. Wald entitled "The Mistress of the World and her Shadow". These meant energy and entropy. In the course of advancing knowledge the two seem to me to have exchanged places. In the huge manufactory of natural processes, the principle of entropy occupies the position of manager, for it dictates the manner and method of the whole business, whilst the principle of energy merely does the book-keeping, balancing credits and debits.

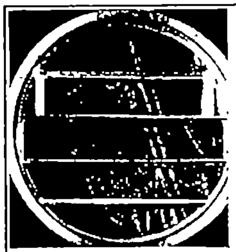
Secondary Effects of the Hard and Soft Components of Cosmic Rays

It has been shown in a previous paper[1] that the major part of the electron showers produced in a lead plate are formed by a 'cascade process' in accordance with the shower theory proposed by Bhabha and Heitler[2] and Carlson and Oppenheimer[3]. Our experiments have been made with an automatic cloud chamber. Four lead plates of 3 cm. thickness are placed inside the chamber in a distance of 5 cm. A cloud chamber divided up in this way offers good opportunity of studying the way in which the showers are generally produced.

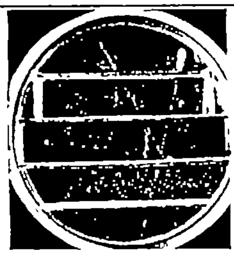
Fig. 1 shows a typical 'cascade process'. In later experiments two counters were used to detect the passage of the particles through the cloud chamber. One was placed above and the other below the chamber in such a position that any ray passing straight through both must also go through the chamber and the four lead plates. The intention was to study the production of secondaries when the primaries pass the lead plates and to make statistical investigations of their frequency in the various sections. Figs. 2 and 3 show some track photographs made in this way. Secondary, not ionizing, light quanta are here seen to have produced ionizing particles near the main ray.

A statistical examination of results, obtained without screening the chamber, gives the following result. Out of every 100 particles (hard plus soft radiation) passing the chamber, 30 were without visible secondary effect. 26 tracks were found in section I, 35 in II, 44 in III, and 45 in IV, the sections being numbered from above. The cloud chamber was then screened with an iron filter of 33 cm. in order to absorb the soft radiation. In this way it was possible to ascertain whether the hard radiation gave the same statistical results as the hard plus soft radiation. The following result was obtained: Out of every 100 particles of the hard radiation, 41 give no visible effect. 18 tracks were found in section I, 21 in II, 22 in III and 23 in IV. Thus the hard radiation gives considerably less secondaries than the hard plus soft radiation. Assuming now that the 30 particles without visible secondary effect in the first experiment all belong to the hard component, we shall find, in agreement with experiments, that the soft component amounts to about 27 per cent of the total radiation at the earth's surface.

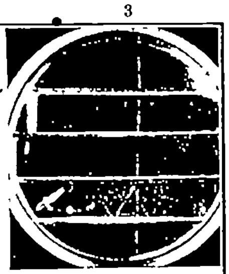
1

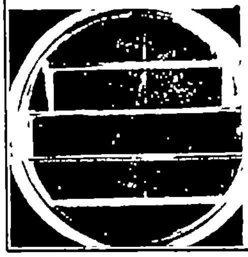


2

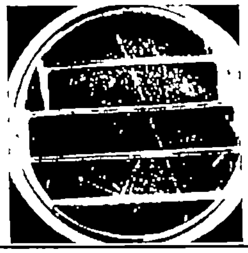


3

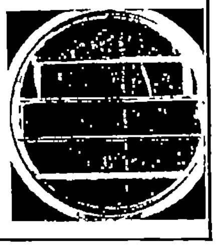




4



5



6

In order by these calculations to get a correct value of this distribution factor, we are furthermore forced to assume that the quantities of hard particles being transformed into soft particles in the filter are negligible. On this assumption, we can now calculate the statistical distribution of secondaries for soft rays alone. We will find that practically all the soft rays give visible secondary effects, and as distinct from the hard rays the number of secondaries increases rapidly from one section to the other in the downwards direction. The number of secondaries stated in this way seems to be in good agreement with the electron absorption theory of Bhabha and Heitler.

The theory has been proposed that the hard rays are electrons having an energy higher than some critical energy above which the quantum absorption theory is not valid. If this be correct, we shall have to assume that the iron filter will decrease the energy of some of the hard particles and in this way produce a new soft radiation component. Our experiments seem, however, to show that this cannot be the case, and consequently we shall have to conclude that the hard particles cannot be electrons.

As to the secondary effect of the hard rays, it might be mentioned that the secondaries most frequently form a branch of the main rays, as shown in Fig. 4. Secondaries—electron pairs and single rays—among which are found strongly ionizing nuclear particles, may, however, also appear at some distance from the main ray according to the effects shown in Figs. 5 and 6. Such cases show that the hard radiation also may be accompanied occasionally by hard light quanta, which are thus able to produce cascade processes. The processes producing these secondaries may be of various kinds, such as nuclear reactions and head-on collisions with subsequent production of light quanta and pairs of the fast secondaries.

A fuller account of these and further investigations will be published elsewhere.

High-Altitude Cosmic Radiation Measurements near the Magnetic Axis-Pole

THE Wordie Expedition of 1937 to Baffin Bay[1] gave us an opportunity of making measurements of cosmic radiation at great heights in the atmosphere near the magnetic axis-pole. Free balloons were used, the method employed being that of Prof. E. Regener, to whom we are very much indebted for invaluable help. Our two most successful flights were made within 5° of the pole, one with an ionization chamber and one with a triple counter set giving coincidences for vertical rays. The result of the ionization chamber flight is shown in Fig. 1 and that of the counter flight in Fig. 2.

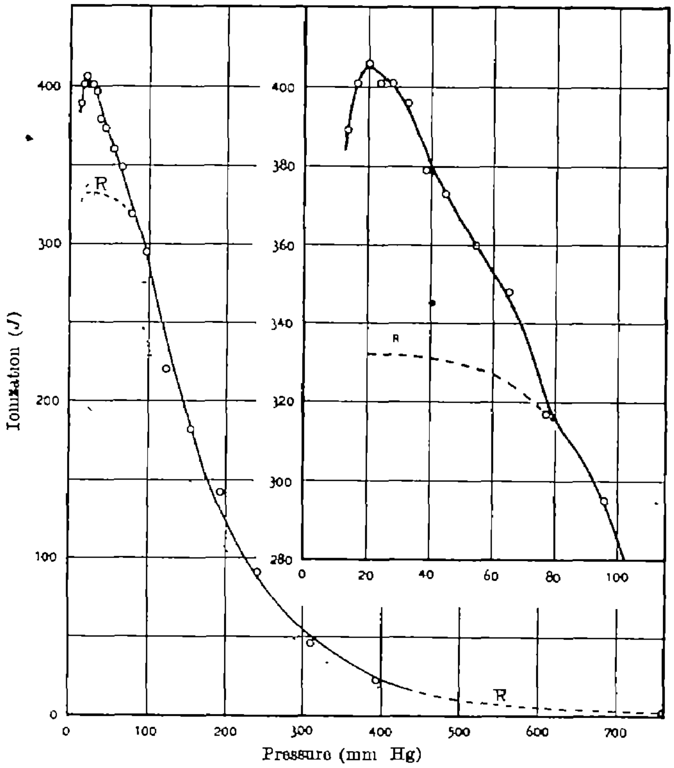

Fig. 1

IONIZATION CHAMBER MEASUREMENTS. .. ... ACTUAL RESULT λ 85°; - - - - - REGENER, λ 49°; ——— λ 85° CURVE INCREASED BY 20 PER CENT.

The ionization chamber was a steel sphere of wall thickness 0·5 mm. and collecting volume 3 litres. It was filled with argon at a pressure of about 6 atmospheres, and the collecting field was everywhere greater than 30 volts per cm. The electroscope was similar in construction to that of Neher[2], but in addition it was made to recharge itself automatically, after the manner of the ticking electroscope of Zeleny. The rate of leak of the electroscope was recorded, along with the pressure of the air and the temperature of the apparatus, on a moving photographic film. Relative values of the cosmic ray ionization are proportional to the rate of leak of the electroscope system and were found directly from the film record. Absolute values in ion pairs per c.c. per sec. in normal air were obtained by measuring the capacity of the electroscope system and converting the ionization in argon so found to that in air. The conversion factor 0·72 was used[3], after it had been checked by experiment with γ-rays. The probable error of the absolute magnitude of the ionization is greater than that of the relative values, except in the lower parts of the atmosphere, and may be taken as ± 5 per cent. The probable error of the pressure measurements is ± 1 mm. mercury, the lowest pressure reached being 12·5 mm. mercury.

The coincidence counter apparatus consisted of three Geiger-Muller alcohol-filled tubes[4] coupled through a conventional Rossi circuit to an 8-metre oscillator designed for the purpose by J. A. Ratcliffe. In order to actuate all three counters, a particle must traverse 0·3 mm. of brass and 4·25 mm. of pyrex. Each particle vertically directed within a cone of semi-angle 20° gave rise to a radio pulse which was received at ground-level by a commercial superheterodyne receiver, and the impulses were counted on a three-stage scale of a two vacuum tube counter. The air pressure was recorded by variation of the wave-length of transmission. This was checked by direct measurement of the height of the apparatus by means of theodolites, and in one flight, when the apparatus was recovered, by a recording meteorograph. The most valuable counter observations were made on this flight at magnetic latitude λ 88°.

The curve *R* in Fig. 1 is that of Regener[5] for λ 49°. It is to be expected that in the lower atmospheric levels the ionization curve near the pole should be identical with that of Regener, and when our curve is increased by 20 per cent, good agreement with Regener is in fact obtained for pressures above 90 mm. mercury. Our experimental points are shown on this adjusted curve. Similar agreement with Millikan and Neher[6] in λ 52° for pressures above 50 mm. (that is, for the whole range of their curve) can be obtained by increasing our results by 60 per cent. It is reasonable to conclude that these differences of absolute value are due chiefly to differences of the wall effect of the ionization chambers used.

The curve obtained near the magnetic pole, if the adjustment of the absolute results is valid, shows larger ionization near the top of the atmosphere than Regener's curve at λ 49°, and at 20 mm. mercury shows a well-defined maximum. It is not possible to say whether the radiation producing this increase reaches the earth at about λ 50° or nearer the pole. The available measurements of Millikan and Neher at λ 52° do not extend quite high enough to decide this point. We hope, however, soon to have flights in Great Britain with the same apparatus.

The coincidence counter results in Fig. 2 are compared with those of Pfotzer[7] taken at λ 49°. The curves are fitted at ground-level and are seen to agree closely at low pressures. At intermediate pressures Pfotzer's curve lies below ours. It should be noted, however, that Johnson[8] at approximately the same latitude as Pfotzer finds a similar deviation. If real, its origin is not clear.

The general conclusion reached by both types of measurement is that the radiation intensity at the pole is approximately equal to that at λ 50°. This is in agreement with the indications given by the results of Cosyns[9] between λ 47° and λ 51°. It is probable, consequently, that the radiation intensity at high altitudes, which increases markedly from the equator to λ 50°, remains thereafter constant to the pole. These experiments indicate, therefore, that cosmic rays of energy less than about 3×10^9 e.-volts either do not exist in space or are prevented from reaching the earth by an agency other than the terrestrial magnetic field. Janossy[10], on the basis of Cosyns's results, has shown that a solar magnetic field of reasonable magnitude will cut off rays of energy less than 3×10^9 e.-volts.

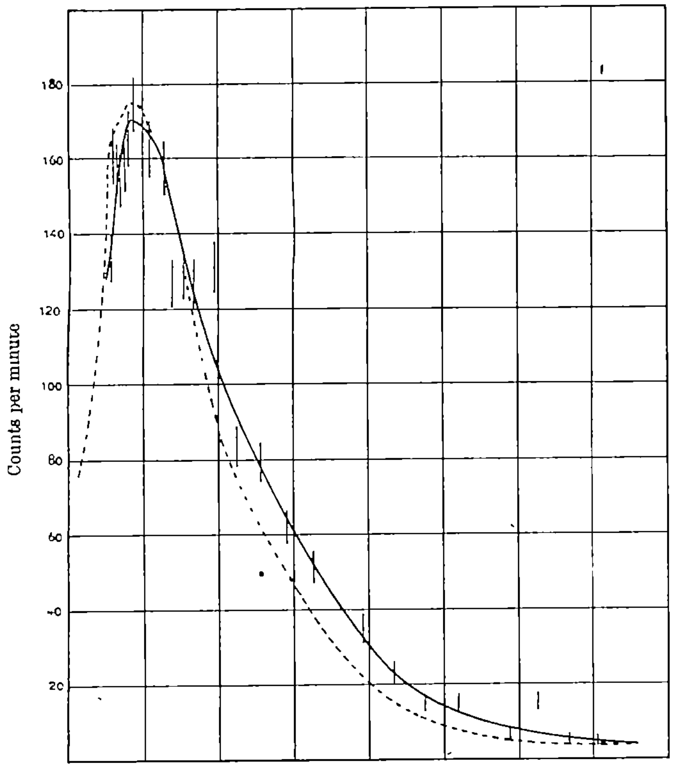

Fig. 2.

Coincidence counter measurements. ——— λ 88° ; – – – – Pfotzer, λ 49°.

We are deeply indebted to Mr. Wordie for providing the opportunity for this work, to all the members of the expedition and of the ship's crew for their help with the flights, and especially to Mr. I. M. Hunter for his work with the radio technique.

Transfer of Helium II on Glass

Kamerlingh Onnes[1] observed in 1922 that the surfaces of two volumes of liquid helium II, that is, helium below the λ point, in two concentric vessels adjusted themselves automatically to the same level. No further observations of this strange 'distillation' phenomenon appear to have been made in Leyden or elsewhere. Rollin[2], however, found that the loss from vessels containing liquid helium II is exceptionally high, and he attributed this to some effect connected with the formation of a thin layer of helium II on the inner walls of the connecting tube. This, he suggested, might be connected with the above-mentioned phenomenon. We have lately carried out experiments with various arrangements of vessels in order to reproduce the effect observed by Kamerlingh Onnes and to investigate it systematically.

In one very convenient apparatus we utilized a small glass beaker suspended on a thin glass fibre which could be lowered into a bath of liquid helium II or raised out of it. The heat influx was reduced to a minimum, 0·5 c.c. of liquid at 1·5° K. evaporating per hour. As it was found that light from an ordinary incandescent filament lamp was absorbed (probably on the glass wall) and disturbed the effect, our observations were carried out with a neon lamp. The following phenomena were observed:

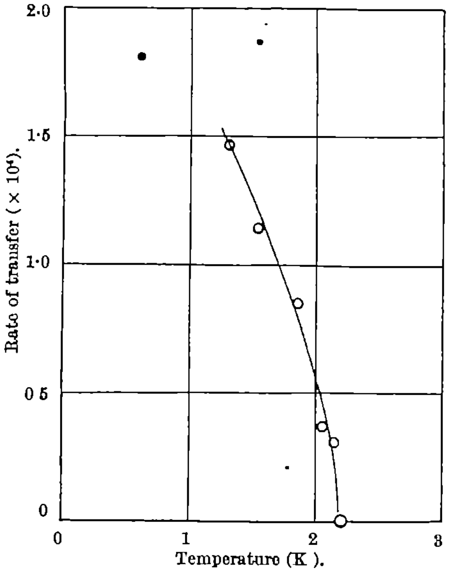
(*a*) When the empty beaker was lowered into the liquid, it filled up to the level of the bath although the rim of the beaker was everywhere above the level of the liquid.

(*b*) When the beaker was partly lifted out of the bath, the level of the liquid in the beaker fell at the same rate as it rose in (*a*), and the level of the bath rose until both had reached the same height.

(*c*) In order to establish whether the transfer took place by distillation through the gas phase or by transfer over the surface, the effect was examined of introducing 'wicks' of twisted copper wire which increased the surface leading from one level to the other. It was found that this increased the rate of transfer to several times the previous rate so long as, but only so long as, the wick reached into the liquid at the higher level.

(*d*) When the beaker (without a wick) was lifted completely out of the bath, it was found that the liquid vanished at the same rate as when it was still partly dipping into it. This was accounted for when it was observed that the liquid collected in drops at the bottom of the beaker and dripped into the bath.

(*e*) The rate of transfer did not appear to differ very greatly whether the beaker was almost full or nearly empty, the rate decreasing only by 20 per cent when the level had dropped from within 0·5 mm. of the rim to some 20 mm. from the rim.



(*f*) As shown in the accompanying figure, the rate of transfer increased rapidly with decreasing temperature. The rate is given in cubic centimetres of liquid per second per centimetre of glass surface cutting the surface of the liquid.

(*g*) If any of these phenomena occur above the λ point, the rate is so slow that they could not be observed in our experiments.

These experiments appear to show that the surface of a solid in contact with liquid helium II is covered with a helium film through which the liquid is transferred to the lowest available level. The rate of transfer on glass (it was found to be much higher on copper) appears to be of the order which one would expect if a monatomic layer were to move with the average kinetic velocity of the molecules. But the fact that the rate of transfer increases rapidly with falling temperature seems to indicate that the phenomenon depends not so much on the molecular velocity as on the viscosity, which decreases[3] as the temperature falls. Whether this is to be attributed to the obvious explanation that the de Broglie wavelength increases with falling temperature is a question which must be left until further experiments have enabled a more complete theory of the two phases of the liquid state of helium to be evolved.

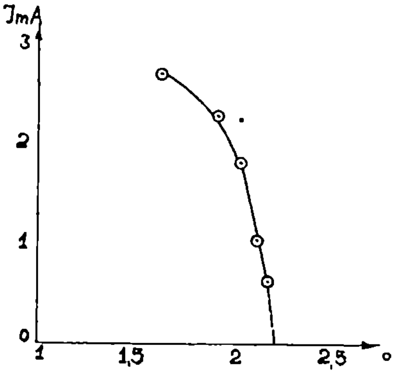
Experiments with Liquid Helium II

N. Kürti, B. V. Rollin and F. Simon[1] found that below the λ-point liquid helium slips over the surface of the tube lowered into it. They observed this phenomenon by increasing the flow of heat along the tube. We have made a more detailed investigation in order to obtain some quantitative characteristics of this phenomenon. We used the following method.

A glass tube 4 mm. in diameter, insulated by a vacuum vessel, is immersed in liquid helium with only its lower part surrounded by the liquid ; and the remainder is allowed to project above the level of the liquid helium bath. On the upper parts of the glass tube a copper tube is soldered, on to which a heating coil of constantin wire (0·1 mm.) and a resistance thermometer of phosphorbronze wire (0·1 mm.) are wound.

When the lower part of the tube is surrounded by liquid helium II, its upper part has the same temperature as the lower part, that is, the temperature of the liquid helium in the Dewar vessel. When heat was introduced electrically by means of the heating coil, almost no heating is observed (the temperature gradient in this case is approximately 2×10^{-4}° K.). At a fixed value of the current, intensive heating begins. The value of this limiting current depends on the height of the thermometer above the level of the liquid helium in the bath and also on its temperature ; it increases with decreasing height and with the decrease in temperature of the liquid helium. The dependence of the limiting currents upon the height is, however, very weak. In the accompanying graph, the values of the limiting current are plotted against the temperature. When the current in the heating coil is switched off, the upper part of the tube very rapidly (in a few seconds) acquires the same temperature as that of the lower part.

When the Dewar vessel is filled with liquid helium I, this phenomenon does not occur ; with the smallest values of current in the heating coil, the upper part of the tube is warmed, and on switching off the current the temperature equalizes very slowly (because of the heat conductivity of the tube and of the wire).



It appears that over the surface of the tube a fine film of liquid helium II is formed, which, owing to its abnormally high heat conductivity, equalizes the temperature of the upper and lower parts of the tube, even although the height of the thermometer above the level of the liquid is comparatively great (about 150 mm.). This film at the limiting value of the current evaporates, and only then does the heating begin. The phenomenon takes place even with a metallic tube.

From the values of the limiting current and that of the heat of evaporation of liquid helium, it is possible to estimate very roughly the thickness of the film. It appears to be of the order 10^{-5} cm. We obtained the same value when we determined the thickness from the value of the temperature gradient along the film, if we assume the heat conductivity of liquid helium to be 10^4 cal./gm.cm.sec., as found by Allen, Peierls and Zaki Uddin[2]; in their experiment the temperature gradient was of the same order as ours.

Kapitza recently supposed that the abnormally high thermoconductivity of helium II can be explained by the presence of strong convection currents in helium; it is evident, however, that with such extremely thin films as in our case (10^{-5} cm.) such convection currents could scarcely be formed.

At present, experiments on the direct determination of the film thickness are in preparation, and a detailed description of them will shortly be published.

Transport Phenomena in Helium II

F. London[1] has recently proposed a new conception of helium II, according to which this liquid can be regarded as a degenerate Bose-Einstein gas, that is, as a system in which one fraction of the substance—say, n atoms per cm.^{3}—is distributed over the excited states in a way determined by the temperature, while the rest—$n_0 - n$ atoms per cm.^{3}—is 'condensed' in the lowest energy level. If T_0 denotes the temperature of degeneracy, the ratio n/n_0 is given by

$$n/n_0 = (T/T_0)^s \text{ for } T < T_0 \qquad (1)$$

For an ideal Bose-Einstein gas, according to London, $s = 3/2$, but for the real fluid one should rather insert $s = 5$ in order to fit Keesom's specific heat measurements.

The calculation of viscosity of a degenerate Bose-Einstein gas is in progress. A preliminary estimation shows that the atoms belonging to the lowest energy state do not take part in the dissipation of momentum. Thus, the viscosity of the system is entirely due to the atoms in excited states. This simple description allows us to account in a qualitative way for the well-known transport phenomena in helium II, though in the more exact treatment certain modifications have to be introduced, which are to be discussed in a detailed publication.

(1) Measurements of the damping of an oscillating cylinder will show the effect of atoms in excited states only. To a first approximation the viscosity, measured in this way, should be the same as the viscosity of helium gas at the same temperature. The value of the viscosity coefficient of helium gas at $T \sim T_0$ is $\mu \sim 10^{-5}$ c.g.s. units[6], while measurements in helium II just below the λ-point[2] give $\mu = 3 \times 10^{-5}$. Parallel measurements of the viscosity of helium II and helium gas in the corresponding range of temperature would provide us with an indication as to what extent the simple picture adopted here has to be refined.

(2) It is, however, not the viscosity coefficient μ which determines the flow velocity of helium II moving under the influence of a pressure gradient through a capillary. In this case, the fraction of substance consisting of atoms in the lowest energy state will perform—like a 'superfluid' liquid of viscosity $\mu \sim 0$—some sort of turbulent motion the flow velocity of which does not depend on the bore of the capillary. In addition, the atoms in excited states, behaving like a gas of pressure $\sim nkT$, will diffuse in a similar way to, say, molecules in a solution under the influence of a gradient of osmotic pressure. Thus, the total flow represents a rather complex combination of both these effects. It will largely depend on the ratio $(n_0 - n)/n$ and, therefore, on T, in agreement with experiment[3]. According to this interpretation, a temperature gradient should arise during the flow of helium II through a thin capillary.

(3) The so-called fountain phenomenon[4] of helium II is an inverse process to (2). If one maintains a temperature difference between the ends of a capillary, a gradient of density of excited atoms, n, and, thus, of pressure is produced. In consequence, (*a*) the excited atoms will diffuse towards the colder end, and (*b*) the super-fluid fraction of the liquid moves in the opposite direction. In the case of a wide tube, these currents must be equal and no resulting flow will be observed. If, however, the capillary is sufficiently narrow, the rate of the process (*a*) becomes reduced and the temperature gradient causes a surplus convection current opposite to heat flow. This picture can account for the great values of the heating current required to maintain a temperature difference at the ends of the capillary[5]. Simultaneous measurements of the heating current and the total convection of substance could provide us with information about the relative magnitude of the processes (*a*) and (*b*).

A detailed discussion of the problem will be given in the *Journal de Physique*. I am greatly indebted to Dr. F. London for the opportunity of seeing his paper before publication.

A Simple Inexpensive Ultracentrifuge

In designing quantitative ultracentrifuges costing only a few pounds and available for measurements of sedimentation velocity and of sedimentation equilibrium, it is clearly best to adopt the simple modification of the air-driven spinning top of Henriot and Huguenard, in which the essential part of the system is immobilized by mechanical baffles[1]. This dispenses entirely with an optical system and depends upon direct analysis of the liquid after ultracentrifuging, using any suitable chemical, physical or biological method. Such opaque ultracentrifuges possess the further advantage over any transparent ultracentrifuge that the whole of the column of liquid from its upper surface outwards and from the very beginning of the sedimentation is available, without distortion, for exact measurement.

Cells which are ideally radial are made either from circular disks or from circular annular washers. Spacing pieces which leave the cell completely unobstructed are made from disks or washers of less width. The liquid, which may be aqueous or non-aqueous, is rendered so completely convectionless that the rotor may be stopped and dismantled for analysis without appreciable disturbance. The disks or washers may be made of any solid material that holds its form under the experimental conditions. We have found suitable such as can be cut from sheets of coin silver (10 per cent copper) a few thousandths of an inch in thickness.

Washers are suitable immobilizers for sedimentation equilibrium in any system, as described by McBain and Tostado in the accurate determination of the sedimentation equilibrium of sucrose[2]. Since then, Tiselius, Pedersen and Svedberg[3] have communicated an analytical method applied to the contents of their ultracentrifuge, giving their formula for calculating sedimentation velocity.

We now communicate measurements of sedimentation velocity of egg albumin with the disk method[4] in a 37 mm. rotor driven at 120,000 r.p.m. by air of 60 lb. pressure per sq. in. Each of fifteen attempts has been successful. In the last five the ultracentrifuge was held at constant known temperature to within 0·1° C. by the simple device of passing the driving air through a copper coil in a thermostat. Any desired temperature may be selected and held constant to within 0·01° C.

It is obvious that the same result should be arrived at whether the amount of protein leaving the immobilized liquid or arriving in the outer liquid is determined. About 2·2 c.c. of liquid is employed.

The results are expressed as sedimentation velocity in water at 20°. Analysis of the outer liquid gave $s_{20} = 3{\cdot}68$, $3{\cdot}69$, $3{\cdot}40$, $3{\cdot}59$, and $3{\cdot}64 \times 10^{-13}$, respectively; mean $3{\cdot}60 \times 10^{-13}$. Analysis of the inner liquid gave $s_{20} = 3{\cdot}35$, $3{\cdot}61$, $3{\cdot}42$, $3{\cdot}89 \times 10^{-13}$, respectively; mean $3{\cdot}57 \times 10^{-13}$. Svedberg's most recent result[5] is $3{\cdot}55 \times 10^{-13}$.

Similar results have been obtained with the same material by A. H. Lewis using an improved form of the McBain-O'Sullivan transparent ultracentrifuge[1]. Incidentally, these observations show that there is no wall effect upon velocity of sedimentation or diffusion where the spaces are as small as 0·01 mm., as would indeed be expected from hydrodynamic theory. The protein particles or molecules are 20,000 times smaller than the capillary spaces.

Polydisperse systems require that runs be made at several speeds for different times. There is also the advantage that analysis for every constituent may be carried out independently.

Complete details are being communicated elsewhere; the simple equipment was shown at the National Colloid Symposium, Cambridge, Massachusetts, on June 9–11 last year.

Properties of Variable-Width Sound Film as an Optical Diffraction Grating

IN a recent letter in NATURE[1], D. Brown described an ingenious and simple method of obtaining acoustic spectra, namely, by using a strip of 'variable-density' sound film as a diffraction grating for light. If the transparency of the film is modulated by one frequency only, the spectrum obtained will only contain the orders zero and plus and minus one. Higher orders do not occur. If the transparency is modulated by a complicated sound, the place and intensity of the different lines in the spectrum will give immediate visual information on the spectral composition of this sound.

It may be interesting to describe shortly the behaviour of 'variable-width' sound film as an optical diffraction grating.

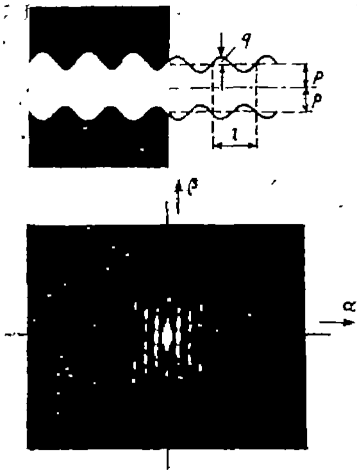

FIG. 1.

The diffraction pattern of a single frequency obtained with a point source of monochromatic light ($\lambda = 5461$ A.) is shown in Fig. 1. The point of symmetry corresponds with the direct image of the light source, the vertical line through it with the order zero, the first vertical line on each side with the order one. It is clearly seen that now higher orders are also present. Visually as many as twenty orders could easily be perceived.

The intensity of the light along a vertical line of order n, apart from an immaterial constant, is given by:

$$\frac{1}{\beta^2} \cdot \sin^2\left(\frac{2\pi\beta p}{\lambda} + \frac{n\pi}{2}\right) . J_n^2\left(\frac{2\pi\beta q}{\lambda}\right) \quad . \quad . \quad . \quad (1);$$

where $2p$ is width of zero track; q is maximum amplitude of modulation on both sides; l is length of period; λ is wave-length of the light; J_n is a Bessel function of order n; β is angle of diffraction in vertical direction; $\alpha = n\lambda/l$ = angle of diffraction in horizontal direction.

It can be easily derived from (1) that the intensity along the α-axis ($\beta = 0$) is identical with the intensity obtained with variable-density film, if the same percentage modulation is used. Thus all orders higher than one vanish, as can be seen in Fig. 1.

The intensity along a line of order n is mainly given by a Bessel function of that order. A Bessel function of order n remains practically zero for low values of the argument and reaches its first maximum for a value of the argument equal to approximately $n + 1$. This accounts for the peculiar cross-like shape of the diffraction pattern. The legs of the cross can be shown to stand perpendicularly to the maximum gradient of the sound track. The intensity is furthermore alternatively given by a sine for even and a cosine for odd orders. This explains the set of equidistant zeros, which may be called p-zeros. An alteration of the modulation q only affects the q-zeros determined by a Bessel function and thus only alters the shape of the cross. Alteration of the width of the zero track $2p$ only affects the distance of the p-zeros determined by a sine or cosine.

The formula (1) given here is the formula for bilateral modulation. If unilateral modulation is used, the trigonometric factor vanishes for all orders but zero, so that the intensity for these orders is given by a Bessel function divided by its argument.

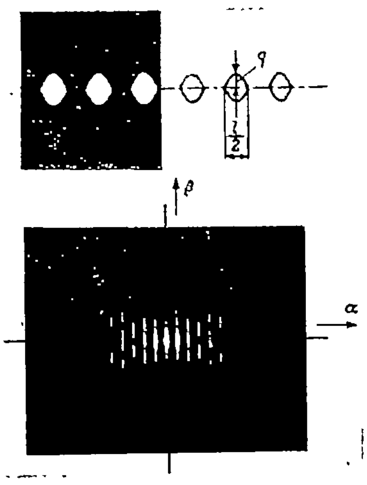

FIG. 2.

If more frequencies are present in the sound, the intensity along the α-axis is again identical with the intensity obtained by variable-density film and thus provides a visual Fourier analysis of the sound.

An interesting example is shown in Fig. 2. The width of the track is $q \sin 2\pi x/l$ from 0 to $l/2$ and zero from $l/2$ to l. In sound film practice this corresponds to zero value of the zero track. The Fourier spectrum only contains the orders 0, 1, 2, 4, 6, 8 . . . Higher odd harmonics should not be present. Fig. 2 confirms this expectation : along the α-axis only even higher harmonics are present.

For odd orders the intensity is given by

$$\frac{1}{\beta^2} \cdot J^2_{2n+1}\left(\frac{2\pi\beta q}{\lambda}\right) \quad . \quad . \quad . \quad . \quad (2);$$

and thus, but for the trigonometric factor, identical with (1). For even orders, however, the intensity is given by

$$\frac{1}{\beta^2} \cdot \Omega^2_{2n}\left(\frac{2\pi\beta q}{\lambda}\right) \quad . \quad . \quad . \quad . \quad . \quad (3)$$

where Ω_{2n} stands for a Weber-Lommel function of order $2n$. For small values of the argument, Weber-Lommel functions of even order can be represented by the first power of the argument. The intensity along the α-axis is therefore different from zero. For higher values of the argument the behaviour of Weber-Lommel functions is very much like that of Bessel functions, appreciable intensities not being reached for values of the argument lower than the order. The observed zeros are in very good agreement with the calculated ones.

The original idea of Brown has hereby been greatly extended. Whereas the behaviour of variable-density film can be deduced immediately from the theory of optical gratings, this is not the case for variable-width film. It would seem that to the two well-known types of optical gratings, modulation of the amplitude and modulation of the phase of the incident light, a third new type, modulation of the width of the grating, is added.

Specific Heat of Carbon Dioxide at Low Temperatures

A NEW Raman line with $\Delta\nu = 58$ cm.$^{-1}$ was observed by us[1] in the Raman spectrum of solid carbon dioxide at − 80° C. Since the heat capacities of solid carbon dioxide at low temperatures are known[2], it may be of interest to examine whether these values agree with those obtained from a corresponding Debye function. If the value of $\Delta\nu$ of the observed new line be taken as 63 cm.$^{-1}$, in view of the fact that this value increases slightly at low temperatures in other cases, the value of $h\nu/k$ is 90·3°. If the line be due to lattice oscillation, the values of C_v should be given by the corresponding Debye function with three degrees of freedom, because the crystal being cubic, ν has the same value for the three degrees of freedom. The calculated values are given in the second column of the accompanying table, and the observed values of C_p are given in the last column. It can be seen that the former are much greater than the latter at low temperatures. This shows that the new line is not due to a lattice oscillation involving translational motions of the molecules.

T	C_v for D.F., $\theta = 90·3$	C_v for two E.F., $\theta = 90·3$	C_v for one E.F., $\theta = 90·3$ and D.F., $\theta = 168·8$	C_p observed
19·4	2·46	0·836	1·08	1·08
22·0	2·91	1·144	1·49	1·46
25·4	3·41	1·524	2·04	2·06
31·8	4·11	2·11	3·04	3·28
37·8	4·55	2·518	3·85	4·38
44·2	4·88	2·838	4·58	5·46

Again, if the new line be assumed to have its origin in angular oscillations postulated by Pauling[3], its contribution to the heat capacity would be equal to that of two Einstein functions corresponding to two degrees of freedom perpendicular to the axis of the molecule. These values, given in the third column of the table, when compared to the observed values of C_p, show that the contribution of some other Debye function, which has to be taken into consideration, becomes superfluous. Hence the new line cannot be due to these angular oscillations.

The contributions to C_v of one Einstein function with $\theta = 90·3°$ and of a Debye function with three degrees of freedom and with $\theta' = 168·8°$ agree fairly with the observed values of C_p, as can be seen from the last two columns of the table. The observed values of C_p at higher temperatures are higher than the calculated values of C_v, probably because the value of $C_p - C_v$, and also the contribution due to angular oscillations, become appreciable. The observed heat capacities therefore show that, besides the lattice oscillations, another oscillation responsible for the origin of the new line takes place at low temperatures, the nature of the oscillation being such that its contribution to C_v is that of the corresponding Einstein function. It appears that this oscillation takes place in pairs of carbon dioxide molecules, the molecules in each pair being connected to each other by a weak electronic bond.

Structure of the Methane Molecule

AN explanation of the complex rotational fine structure of the 1306 cm.$^{-1}$ fundamental vibrational band of methane[1] has been found which is based on a tetrahedrally symmetrical model for the molecule. The cause of the splitting of the rotational lines is a Coriolis coupling between the rotational levels of this threefold degenerate mode of vibration ν_4 and the rotational levels of the infra-red inactive twofold degenerate vibration ν_2 at 1536 cm.$^{-1}$, which lies 230 cm.$^{-1}$ above it. The perturbation is appreciable in spite of the distance between the pairs of levels concerned, because the Coriolis coupling term in question is essentially a first-order term in the Hamiltonian. A general expression for this term in methane was given by one of us in a previous paper[2]. It involves the components of vibrational angular momentum obtained by combining the displacements of ν_4 with the momenta of ν_2 and *vice versa*[3]. It is to be noted that since the two vibrations belong to different symmetry types, the perturbation affects only the rotational levels and leaves the origin of the ν_4 band unaltered.

The perturbation, which produces a splitting as well as a displacement of the rotational levels, has been calculated up to the tenth rotational quantum number. From these perturbed levels a theoretical spectrum has been derived which agrees very well with the observed spectrum, even though we have not taken into account any change in the moment of inertia or any centrifugal expansion of the molecule. These latter effects are therefore probably small. It should be pointed out that theoretical intensities which take into account correctly the nuclear spin weights of the equivalent hydrogen nuclei have not been given before. We have made use of the recent work of Maue[4] to calculate these, and the theoretical intensities agree well with experiment (for example, $R(1)$ and $R(5)$ weak).

It is to be noted that when, as in the low-frequency fundamental of methane, the perturbation comes from above, the levels are all pushed down. This produces, since the perturbation increases with the rotational quantum number, a converging R branch, a diverging P branch and a broad Q branch which extends well into the P branch, thus producing the effects of an apparent increase in the moment of inertia. A perturbation from below would, however, produce just the opposite effect, namely, a divergence in the R branch, a convergence in the P branch and a Q branch extending into the R branch. The fundamental ν_4 of germane (GeH_4) does indeed appear to have this structure[5], and we have here just the required conditions to produce this effect, for the perturbing vibration ν_2 lies below ν_4 (Steward and Nielsen[5] give $\nu_4 = 934$ cm.$^{-1}$, $\nu_2 = 820$ cm.$^{-1}$) (In silane (SiH_4), on the other hand, the Q branch would appear to extend into the P branch[6] and this is in agreement with the assignment of the frequencies ($\nu_4 = 910$, $\nu_2 = 978$) given by Stitt and Yost[7] which makes the perturbation come from above. We would like to believe that the apparent additional Q branch found near 978 cm.$^{-1}$ in the 910 cm.$^{-1}$ band of silane comes from activity being imparted to ν_2 by the perturbation.)

Similar perturbations may be expected in the spectra of all polyatomic molecules possessing a threefold or higher axis of symmetry, for such molecules can have degenerate modes of vibration with a vibrational angular momentum, and if the conditions are fulfilled there may be a large Coriolis coupling between the rotational levels of different bands. Thus, for example, these new effects may be looked for in the perpendicular bands of the methyl halides and ammonia and possibly in the deformation bands of linear molecules.

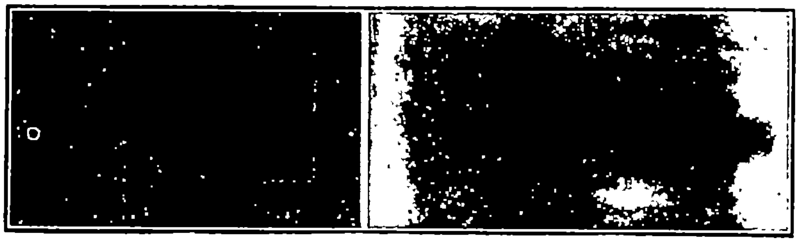
Photographic Action of Artificial Radio-Elements

IN the literature concerning artificial radioactivity, we find no indication of attempts to show the photographic action of radio-elements. Accordingly we decided to carry out a few experiments, the results of which are given below.



(a) (b)

Fig. 1.

It is known that iridium irradiated with neutrons slowed down in paraffin shows a strong activity of period 19 hours. We placed an activated sheet of iridium directly on the emulsion of a photographic plate (Gevaert Super-Press 2,000). After 21 hours, development showed a neat photographic blackening (Fig. 1*a*). Similar attempts were repeated, arranging on the plate two similar iridium sheets, one irradiated, the other not so. The blackening was found only under the irradiated sheet. In subsequent attempts, the sheet was separated from the emulsion by interposing thin aluminium screens arranged in steps of increasing thicknesses : a blackening was found again, the intensity of which changes with the interposed thickness.

One of us (J. G.), having obtained a strong source of radio-phosphorus [1], an exposure of this kind of 48 hours was made with radio-phosphorus ; it gave the result shown in Fig. 1*b*. The copper rod covered with radio-phosphorus was about 1 mm. distant from the emulsion.

These first attempts show undoubtedly the photographic action of artificially produced radio-elements.

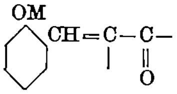
Specificity of the Salicylaldehyde Reaction of Csonka-Straub

A short time ago, Prof. A. E. Braunstein[1] discussed the specificity of the salicylaldehyde reaction proposed by Csonka for the determination of acetone and by Straub for the determination of pyruvic acid, and suggested that a positive reaction is obtained with all compounds containing a CH_3CO group linked directly to a hydrogen or carbon atom, and that the reaction is negative with carbonyl compounds which do not contain the aforementioned grouping. The mechanism responsible for this range of specificity was stated to involve the possibility or otherwise of enolization ensuing in a strongly alkaline medium, leading to the formation of an enolate the colour of which was attributed to a cumulated double bond system.

On this view, ethyl acetoacetate, which gives a positive reaction, must condense through its methyl group and not through its reactive methylene group—a most unlikely occurrence (compare the formation of salicylacetylacetone from salicylaldehyde and acetylacetone). Positive results have been obtained in the salicylaldehyde test with diethyl ketone, propionaldehyde, cyclohexanone and methyl cyclohexanone, all of which on Prof. Braunstein's hypothesis should have given negative results. Prof. Braunstein describes the colours obtained in the test as yellow. While this is true of very dilute solutions, with more concentrated solutions the colours obtained are varying depths of red, changing with dilution through orange to golden-yellow. The limit of detection is attained when the red tint fails to deepen appreciably the lemon-yellow colour given by salicylaldehyde in alkaline solution. Employing a relatively concentrated acetone solution (a few drops in 5 ml. water) in the test, there separate out on prolonged standing dark red prisms with a green metallic lustre, using sodium hydroxide, or glistening bright red leaflets using potassium hydroxide. These have been shown to be the simple alkali salts of salicylacetone (sodium content 12·3 per cent). In very dilute solutions, where there is a large excess of salicylaldehyde, it is, of course, probable that disalicylacetone is also formed.

Similarly, benzalacetone yields a dark red sodium salt giving sodium 8·7 per cent. Acetophenone gives vermilion-coloured needles which on acidifying yield salicylacetophenone. The positive results given in the test by cyclohexanone and 1-methylcyclohexanone are supported by the observations of Borsche and Geyer[2] that the condensation products from salicylaldehyde and cyclohexanone and 4-methylcyclohexanone respectively give red solutions in alkali.

The mechanism of the colour reaction thus involves condensation of the salicylaldehyde with a methylene group in the α-position to an unsaturated group such as carbonyl (CO) and the formation of a simple alkali salt of the resulting compound. The chromophoric grouping is therefore



where M is Na or K. The function of the carbonyl group is to activate the adjacent methylene group. Positive results have been obtained with a 3 per cent solution of cyanacetic acid, in which the methylene group is activated by the unsaturated —C≡N group. Negative results have been obtained with fluorene, the methylene group of which possesses a certain amount of activity, no condensation taking place in this instance.

The range of specificity of the salicylaldehyde reaction is thus by no means so narrow as stated by Prof. Braunstein and the enolization mechanism is untenable. The test is more sensitive for acetone than for any of the other substances examined, which included pyruvic acid, ethyl acetoacetate, acetophenone, benzalacetone, acetaldehyde, propionaldehyde, methyl ethyl ketone, diethyl ketone, cyclohexanone, methylcyclohexanone and cyanacetic acid.

It is hoped to publish full details of the investigation elsewhere in due course.

A New Method of Resolving a Racemic Compound

Since the introduction of Tswett's technique of chromatographic adsorption, this process has been applied successfully to the separation of many isomeric or closely related substances, including the chlorophylls and the components of natural carotene. A few attempts have also been made to employ it for the resolution of racemic compounds by use of an optically active adsorbent, but without positive results.

After examining a number of cases, we have now succeeded in effecting a partial resolution of inactive *p*-phenylene-*bis*-iminocamphor, $C_{10}H_{16}{:}N.C_6H_4.N{:}C_{10}H_{16}$, in the following manner. A weak solution of the compound in petroleum-benzene mixture (8 : 1) was allowed to flow down a tube filled with solid lactose, when the compound was adsorbed forming a broad pale yellow band in the upper part of the tube. The adsorption band was then 'developed' by washing it with the same solvent mixture until the faintly coloured layer practically filled the tube. On pushing the lactose column out of the tube, dividing it into four quarters and recovering the adsorbed material from the top and bottom fourths, respectively, by extraction with chloroform, a partial resolution was found to have occurred. *d-p*-Phenylene-*bis*-iminocamphor is more strongly adsorbed on lactose than its lævorotatory isomeride, and the product recovered from the upper fourth gave after purification from a trace of lactose, $[\alpha]_D + 90°$ (in chloroform): the product from the lower fourth had $[\alpha]_D - 50°$, both values remaining unchanged after further crystallization. As pure active *p*-phenylene-*bis*-iminocamphor has $[\alpha]_D \pm 1{,}500°$, the above process represents a separation of the dextro form in about one sixteenth of its maximum optical purity. Experiments are in progress with the object of increasing this degree of separation. When completed, the details will be published elsewhere.

As is well known, the success of chromatographic adsorption methods rests largely upon the correct choice of solvent and adsorbing medium. The facts recorded above thus open the way to further investigations which may lead to the discovery of cases in which resolution is more readily achieved. The method has the advantage that it is not dependent upon the presence in the asymmetric molecule of a carboxyl, amino or other chemically reactive grouping.

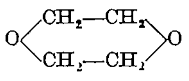
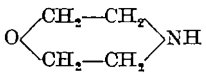
Dipole Moment and Structure of Morpholine

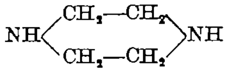
WE have determined the dipole moment of morpholine* in benzene solution at 20° and have obtained a value of 1·48 (Debye units are used throughout). The result is of interest as the structure of morpholine (II) can be compared with those of dioxan (I) and piperazine (III).



I



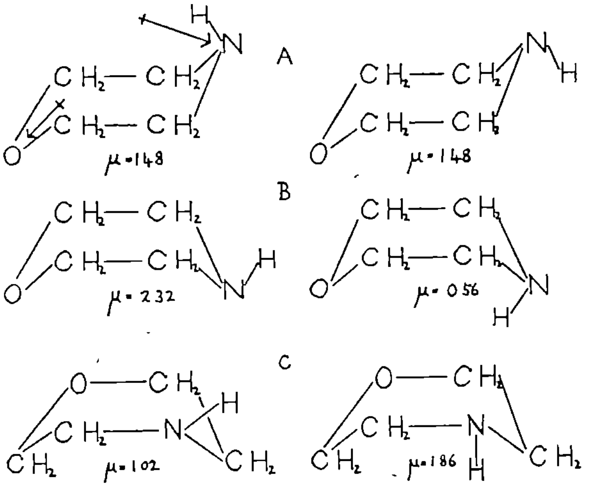
II



III

There are three possible configurations of the six-membered dioxan ring[1]. The Sachse *Z*-form would have zero moment, while the moment of the symmetrical *U*-form would be approximately 2, and that of the unsymmetrical *U*-form would be approximately 1. The experimental value of the moment of dioxan is 0·4–0·5, both in benzene solution and in the vapour state[1,2]. Kubo[1] concludes that dioxan exists in the *Z*-form, but there may be a small amount of either of the *U*-forms present.

In the case of morpholine, there are two possible *Z*-forms and two symmetrical *U*- and two unsymmetrical *U*-forms, because in each case there are two positions which the hydrogen atom attached to the nitrogen can take up with respect to the rest of the molecule. We have calculated the moments of the six forms using atomic distances and angles from recent work on electron diffraction[3]. The moment of ether (average value 1·18) has been used for the $\mathrm{O}\langle^{\mathrm{C}}_{\mathrm{C}}$ group moment and that of diethylamine[4] (1·13) for the $\mathrm{HN}\langle^{\mathrm{C}}_{\mathrm{C}}$ moment. The direction of the latter moment was calculated from those of ammonia and triethylamine, and was found to make an angle of 80° with the CNC plane. The moments of the six forms, that is, the *Z*-forms (*A*), the symmetrical *U*-forms (*B*), and the unsymmetrical *U*-forms (*C*) are shown in the accompanying diagram.



The experimental value of 1·48 agrees with either of the two *Z*-forms, and from the results for dioxan it seems that this is the most probable interpretation. The possibility of small amounts of the four *U*-forms cannot be entirely excluded.

Piperazine, for which a moment of 1·47 has been found in benzene solution by Martin and Partington[5], is an analogous compound for which there is a larger number of possible configurations. Assuming a *Z*-form of ring for this compound, and that all positions of the hydrogen atoms are equally probable, calculation gives a value of 1·52, in good agreement with experiment.

The complete results will shortly be published.

Biological Sciences

Halteres of Flies as Gyroscopic Organs of Equilibrium

IN insects belonging to the group Diptera the second pair of wings is modified into a pair of dumb-bell shaped organs, called halteres or balancers, which consist of a thickened base bearing numerous sense organs, a shaft, and a swollen blood-filled end (Fig. 1, A). During flight the halteres are vibrated rapidly through an arc of about 90° in the vertical plane with a frequency which is almost certainly identical with that of the wing beat. In *Calliphora*, *Lucilia* or *Phormia* this is about 200 times per second.

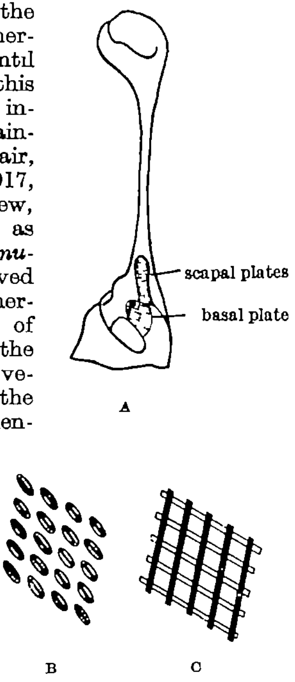

Fig. 1.

It has been known for a long time that without halteres the insect cannot fly, but otherwise behaves normally. Until about twenty years ago, this was attributed to the inability of the animal to maintain its equilibrium in the air, but v. Buddenbrock (1917, 1919[1,2]) rejected this view, and regarded the halteres as "stimulation organs" (*Stimulations-organe*) which served to stimulate the central nervous system into a state of activity indispensable for the execution of the flight movements. We have come to the conclusion that v. Buddenbrock's conception of a purely stimulatory function for the halteres is wrong and that the old balancer theory is in principle correct. The following are the main points of the experimental evidence :

(1) In flies deprived of their halteres, flight can always be induced through the so-called flight reflex, that is, by lifting the fly off the ground and suspending it freely in the air[3]. Certain species (*Phormia terra-novae R.-D.*, *Lucilia sericata* Mg.) fly under these conditions for as long as normal flies.

(2) It is confirmed that immediately after removal of the halteres the flies do not take to flight spontaneously and cannot be startled as readily as normal flies. But they become almost indistinguishable from normal individuals in this respect when tested one day after the operation. This suggests that the temporary loss of spontaneity is caused by a shock effect.

(3) The amplitude and frequency of the wing beat after the operation are identical with those of normal flies.

(4) Flies without halteres show a complete loss of control in the air and often fall on their backs, whereas those which are merely fatigued or have had their wings clipped fly downwards steadily and alight perfectly.

(5) This loss of control is particularly marked with regard to rotations about a vertical axis. Flies suspended freely from a piece of thread in the normal position spin irregularly round this axis.

(6) The loss of equilibrium in a fly without halteres can be almost eliminated by fixing a piece of cotton to the tip of the abdomen. This stabilizes the flight and largely compensates for the loss of equilibrium otherwise observed.

The mechanism by which the haltere acts as an equilibrium organ can be deduced from a study of the anatomical arrangement of the sense organs at its base. The most numerous type of organ present is the campaniform sensillum, the mode of action of which has recently been described by one of us (Pringle, 1937[4]) from experiments on the cockroach. On the legs of that insect the sensilla were found to be sensitive to the shearing strains set up in the exoskeleton by muscular activity, and a theory was developed to relate this behaviour to the structure of the sensillum.

The arrangement of the sense organs of the haltere base has been described accurately by Pflugstaedt (1912[5]). On the basal plate the sensilla, each of which consists essentially of an oval hole in the exoskeleton bridged over the top by a thin membrane, lie in regular rows and show a definite orientation in a direction which is diagonal to the length of the haltere (Fig. 1, B). The cuticle of this plate is so pierced with sensilla that its mechanical properties can differ little from those of a trellis (Fig. 1, C), which is relatively strong or weak in shear according as the resulting lines of compression and extension lie parallel to or diagonal to its component strips.

In flight the vertical vibration of the halteres will produce forces in the skeleton of its hollow base, and these will normally be of the type to which the basal plate is most resistant. Further, the sensilla of the plate, owing to their diagonal orientation, should be insensitive to such forces (Pringle, 1937[4]). If, however, while the halteres are in rapid movement, the whole body of the insect is rotated in any plane not that of the haltere vibration, lateral shearing forces will be set up in the cuticle of the base due to the gyroscopic action of the end knob ; and to these the basal plate should be least resistant and its sensilla most sensitive. The secondary forces due to the rotation will alternate at a frequency related to that of the haltere beat, and the sensilla will be excited at each cycle.

The haltere may thus be regarded as an alternating gyroscope, and the two organs, which are inclined backwards on each side at an angle of about 60° to the long axis of the body, could act together as an efficient equilibrium organ for fore-and-aft and directional stability. The experimental work shows that it is particularly in these planes of movement that balance is impaired by haltere removal.

The substance of this communication will be further discussed in separate papers dealing with its different aspects.

Salinity Tolerance and *p*H Range of *Culex fatigans*

IN a paper on the biology of *Culex fatigans* Wied. in the Belgian Congo, Drs. Wanson and Nicolay[1] state that "at Banana the larval cycle is accomplished normally in concentrations of up to 30 grams of chloride per litre". Taking this figure as representing the total chlorides present, the salinity, $(S^\circ/_{oo})$, expressed as total weight of salts in grams per 1000 gm. of sea water, would be in the vicinity of 33·5. Hamlyn-Harris[2] states that in Queensland this mosquito rarely breeds in brackish water. No other references to *Culex fatigans* Wied. breeding in saline waters have been found, and it is generally regarded as a typical freshwater mosquito.

In a recent series of experiments carried out at Sydney, laboratory cultures of *C. fatigans* were reared in various dilutions of sea water, using tap water as a control.

The general technique of breeding was similar to that previously described by me[3].

It was found that larvæ would not develop normally in water with a salinity greater than 10 gm. per 1000. Where the salinity was very gradually raised during larval development, about 60 per cent of adults emerged from $S^\circ/_{oo}$ 11, about 15 per cent from $S^\circ/_{oo}$ 12, and none from $S^\circ/_{oo}$ 16. When first stage larvæ were transferred directly from $S^\circ/_{oo}$ 0 to $S^\circ/_{oo}$ 12, all died within a few days. Fourth stage larvæ transferred directly from $S^\circ/_{oo}$ 0 to $S^\circ/_{oo}$ 12 gave approximately 1 per cent of adults, and no adults emerged from large series transferred to $S^\circ/_{oo}$ 13·5.

All control series gave 100 per cent adults. Pupæ, on the other hand, transferred from $S^\circ/_{oo}$ 0 to $S^\circ/_{oo}$ 70 gave 100 per cent adults, while from $S^\circ/_{oo}$ 105, 85 per cent adults emerged. It will be seen from this that the pupæ are extremely resistant to high osmotic pressure in the surrounding medium.

With regard to the hydrogen ion concentration, the *p*H was lowered by the addition of dilute acetic acid to tap water, and it was found that 100 per cent of adults would develop from larvæ bred in water the *p*H range of which varied from 3·6 to 4·2. Similarly, by the addition of dilute sodium hydroxide, adults developed normally from larvæ kept in water which varied between *p*H 9·0 and 10·6. It may therefore be concluded that the hydrogen ion concentration in itself has no effect on the development *C. fatigans* within the limits of *p*H 4·2 and *p*H 9.

A detailed account of the experiments on salinity and hydrogen ion concentration will be published shortly.

In view of the importance of *C. fatigans* as a pest species and as a vector of disease, it would be interesting to know whether any other workers have records of it breeding in salt water. Possibly a salt water race of this species occurs on the coast of the Belgian Congo.

Cytology of Metamorphosis in the Culicinæ

PROF. C. A. Berger[1] has apparently overlooked the work of Holt[2], who also investigated the larval gut of *Culex pipiens* during metamorphosis, and described multiple chromosome complexes of 9, 12, 18, 24, 36, 48 and 72 chromosomes. Holt's results do not agree with Berger's conclusion that there is a correlation between chromosome number and cell size in this case, and her illustrations show conclusively that any such correlation is fortuitous. Holt also describes the so-called 'prophase synapsis' of the sister chromosomes of the complex, which pair in three groups ($n = 3$), but she says that the cells with the largest multiples contain vacuoles and show signs of degeneration, and that these cells ultimately degenerate, and are absorbed by the newly formed imaginal cells.

Actually, this synapsis is somatic pairing[3], which was most strikingly shown in Diptera, and especially in *Culex*, by Metz[4], and was first found by Stevens[5]. It is due to attraction between homologous chromosomes, which results in close approximation, but any appearance of fusion is due, Metz showed, to faulty fixation. The chromosomes are not closely coiled round each other, and therefore those torsion stresses which are essential in the production of chromatid breakage and chiasma-formation[3] are not present, and reduction by the ordinary mechanism of meiosis is impossible. Holt believes that the close somatic pairing of the multiple chromosome complexes finishes before the end of prophase, and mitosis is normal. Even were it to persist to metaphase, it would not lead to regular reductional separation, as is demonstrated by the work of Ribbands[6] on the hybrid *Lilium* × *testaceum*, where position correlation of univalents at diakinesis usually leads to their parallel secondary pairing at prometaphase, but nevertheless the distribution of the univalents towards the opposite poles at full metaphase is random.

Bionomics of a Cattle Louse

In the course of a study of the life-histories and bionomics of cattle lice, I have found that the species *Solenopotes capillatus*, End., hitherto considered to be rare in Great Britain, is more common than has been supposed. I found the species first on dairy shorthorn cattle (cows, heifers and calves) at the Cooper Field Research Station, Little Gaddesden, Herts, and further investigations in the neighbourhood revealed the presence of this louse on three other farms. It thus appears that there is a high incidence of *S. capillatus* in Hertfordshire.

While engaged on field work in Scotland in April of this year, I was able to find these lice on cattle at three out of a total of seven farms, where I made examinations. This, I believe, is the first record of the occurrence of *S. capillatus* in Scotland. The localities of the three farms were Strathyre, Perthshire, and Bentpath and Langholm, Dumfriesshire.

These records prove to be more interesting when it is added that examinations conducted on thirteen farms disclosed the presence of *Bovicola bovis* on eleven, *Hœmatopinus eurysternus* on eight, *Linognathus vituli* on five and *Solenopotes capillatus* on seven. The species of sucking lice were confined to nine only of the thirteen farms, which fact signifies a relatively high incidence of *S. capillatus*. With a single exception, the infested cattle were all dairy shorthorns, and the parasites were found on both sexes of all ages, that is, bulls, cows, heifers, bullocks and calves.

The original record and description of *S. capillatus* was made by Enderlein[1] in Germany. Bishopp[2] recorded the species in the United States, where this louse appears to be widely distributed. The earliest record of the occurrence of the species in England (Cornwall) appears to be that of Noel Pillers[3]. Australian records are those of O'Connor[4] (Perth, W. Australia) and McCulloch and Noble[5] (New South Wales). Freund[6], who redescribed this insect in Germany, gives a detailed description of the external anatomy, comparing his observations with those of Bishopp.

The available evidence suggests that *S. capillatus* is widely distributed, and is possibly more important than has been supposed, and, further, that this louse should be included with the other three well-known species attacking cattle, when considering control measures.

Succession in Birthcoat Kemp Follicles

Dr. A. B. Wildman[1], communicating the findings of the late Prof. J. E. Duerden, has recently written about the nature of the successors of birthcoat kemp in the merino, pointing out especially that an original kemp is sometimes followed, in the same follicle, by a fine non-medullated fibre.

In dissections of Romney skin taken about ten weeks after birth, a hair-cone has been found below a club-hair birthcoat kemp. In 1931 at this College, Miss Anthea Hefford showed, among other facts about sweat glands, that the follicle of a birthcoat kemp always possessed a sweat gland, but not so the newly developed follicle of a fibre added to the fleece in the early months after birth. At ten weeks, follicles with sweat glands were found with the tip of a new fibre just protruding from the wide mouth of the follicle. New fibres, similarly short, in follicles lacking sweat glands, were closely gripped by the sheath surrounding the emerging tip. At three months, non-medullated fibres, an inch or a half or so shorter than the long persistent birthcoat fibres, were found in follicles with sweat glands attached. The freedom from medulla of the successors of birthcoat kemps is brought home on examining in the benzol tray specimens from certain covered lambs in which the shed birthcoat kemps stand out at the tip of the staple, while below there is no medulla at all, or just a touch of it in the apical ends of fibres far fewer than the birthcoat kemps.

Differences in the nature of the successors (G_2) of birthcoat kemps (G_1) have been studied, especially on the middle of the back at the level of the attachment of the last rib[2]. For simplicity attention may be focused upon the successors of the largest birthcoat kemps, the halo-hairs, in fibre type arrays containing sickle-fibres, although a parallel story could be related for the 'plateau array', which, typically, lacks sickle-fibres. Amongst the immediate successors (G_2) of halo-hairs the presence of a big proportion of kemps is correlated with the shedding of a substantial majority, usually threequarters or more, of the large-ended sickle-fibres. Reasons have been published for attributing the shedding of kemp to vigour on the part of the follicle.

When there is little G_2 kemp, it has been concluded that the hairiness (medullation) of the persistent successors can, in some measure, be correlated with degree of freedom of shedding of the large-ended sickle-fibres, but that the medullation of these successors tends also to reflect that of large persistent birthcoat fibres, the curly-tip fibres.

Following the G_2 'crop' of kemp there may be another, or even two more crops of secondary kemps grown before the first shearing at some fourteen months. Such later kemp has been found in any abundance only in lambs in which the fibre type array is 'saddle', or a near approach to that array. Such an array is indicative of a mild pre-natal check. In the 'valley array' the pre-natal check is intense. In this array there is much G_2 kemp if halo-hairs are abundant and the large-ended sickle-fibres shed freely, but there is little later kemp (G_3 and G_4). The consequences of a pre-natal event are reaped, it is thus concluded, at the age of nine months.

Preliminary breeding experiments point to genetic factors being of importance in determining the above differences in the 'kemp history' of the fleece of the first year.

Not only does theoretical trichology have practical significance in wool production, but also that somewhat large domesticated animal, the sheep, grows good material for pure zoology.

Acclimatization in Relation to Livestock Improvement

THE problem of the acclimatization of breeds of livestock exported from one country to another is interesting. Certain breeds quickly adapt themselves to certain environmental conditions far removed from those under which they were reared. But, generally speaking, the importation of domesticated breeds into countries of different climatic and soil conditions is regarded as a somewhat risky enterprise. The genetic constitution of the modern breeds has so changed during the last hundred years that many of them depend entirely upon human assistance, and have lost, to a great degree, the ability to live under natural conditions. If this happens in a country, it may be advisable to import foreign breeds of strong constitution which are better adapted than the local breeds, weakened through the continued use of false standards of selection over many generations.

An example of this is to be seen in the Zoological Garden at Warsaw. The European wild deer (*Cervus Elaphus*), from the forests which surround that city, when kept in the open paddocks at the Zoo during the winter, are very susceptible to colds, and usually succumb to pneumonia. On the other hand, the spotted wild deer, imported from India, running in similar paddocks and receiving similar treatment, show signs of robust health and maintain good condition throughout the winter. This observation is confirmed by others and appears to hold good for other Mammalia imported to Warsaw from the tropics.

Accordingly, one is forced to the conclusion that the genotype of the European deer has been weakened. These wild deer of Europe are kept under abnormal conditions. Not only is natural selection removed, but also, since the sportsmen shoot the best males, it is the least thrifty specimens that produce the next generation. These wild deer have to be artificially fed during the winter.

Accordingly, consideration of the problem of acclimatization of domesticated animals in European conditions must include the weakened condition of domesticated strains. It appears to me that this emphasizes the need for skilful selection on the part of the breeder of these domesticated strains, and that this is a more important factor in economical production than suitable environmental conditions. But, of course, the progressive breeder will make his choice of the right breed in its right environment.

Sources of Calcium for Shell of *Ostrea virginica*

THE letter by Robertson and Pantin on "Tube Formation in *Pomatoceros triqueter* (L)"[1] points to the sea water as the source of the calcium required for the building of tubes. It is of interest that a similar condition apparently obtains in the case of *Ostrea virginica*. My observations in 1932–33[2] on the growth of oysters in Long Island Sound show that the deposition of the shell material continues throughout the winter even when other activities of the organism are reduced to the minimum. The weight of the shell increased when the temperature of the water dropped below 4° C. and the oysters were in a state of hibernation, unable to take in any food. During the same period the weight of the tissues remained constant. In view of the fact that there is no storage of calcium in the body of the oyster, an inference can be made that calcium and other salts required for the building of shells are taken in directly from the sea water.

Toxicity of Mercury Vapour to Insects

Christensen, Krogh and Nielsen[1] have referred to the highly toxic effects of mercury vapour in a closed experimental chamber, and recorded the effects on mammals of this vapour arising from droplets of mercury spilled accidentally on the chamber floor. Previously Krogh[2] found a very high mortality among insect embryos on which he was carrying out respiration experiments. He attributed this to the toxic action of mercury vapour from minute drops of mercury which were always left in the tap-borings of his air sampling tubes. He states that it was known from unpublished observations of the Copenhagen physiological laboratories that mercury vapour was highly toxic to insect eggs. Burkholder[3], who cited Krogh's paper, found that eggs of the grasshopper, *Melanoplus differentialis* Thomas, died in a glass respirometer which had been calibrated with mercury although the mercury had been removed prior to the experiment.

Whilst carrying out toxicity tests on eggs of the bed-bug, *Cimex lectularius* L., in a fumigation apparatus containing mercury, I observed a high mortality amongst the controls. At 23° C. all the control eggs were killed in less than twelve hours. I traced this to the effect of mercury vapour, and found that other stages of the bug were only affected after several days' exposure. I also found that eggs of the flour beetle, *Tribolium confusum* Duv., were all killed within less than twenty-four hours, whereas other stages of this insect were unaffected by exposures of one week.

As mercury is extensively used in biological apparatus and the literature concerning its toxicity is very scattered, a note on the subject may be useful to other workers. The literature cited here does not pretend to be exhaustive, as observations on this phenomenon made by physiologists are not necessarily indicated by the title of the paper in which they are mentioned or noticed by abstractors.

Kunhi Kannan[4] first directed attention to the custom of Indian peasants of protecting stored pulses from pests by placing a drop of mercury in an excavated soap-nut in the receptacle used for storing. Though the practice had nearly died out, he investigated it and his results showed the value of what had long been regarded as a superstition. He pointed out that the action of the mercury vapour was only on the eggs of the insects concerned. Larson[5], acting on a suggestion of Kunhi Kannan's, found that both eggs and young larvæ of *Bruchus quadrimaculatus* F. were killed by exposure to mercury vapour. Dutt and Puri[6] confirmed the statement that it was insect eggs that were particularly affected, finding it true of several species of stored products pests and other insects. A dust containing metallic mercury as the toxic principle was found to be effective against pests of cereals by Cartwright[7].

On the other hand, Bovingdon[8] found no detectable difference in the results of fumigation experiments on adults of *Calandra* spp. and *Tribolium* spp., some of which were exposed to mercury vapour and others which were not. In the latter, the mercury vapour was trapped by passing the gas mixture containing it over gold foil.

There seems to be ample proof, however, that mercury vapour is highly toxic to insect eggs. Though other stages are not so seriously affected, it would probably be wisest to avoid the use of exposed mercury altogether in experimental work with insects and possibly other organisms.

Blood Groups and Pigmentation

THE physical characters of the population of Rachrai (Rathlin Island, Northern Ireland) have already been described[1] and compared with those of the people of Sheffield[2].

A recent survey of the blood groups of the two peoples shows significant relationship between the stages of evolution of the blood group genes and those of the factors for hair and eye colour. Observations of blood grouping and of hair and eye colour were made on thirty males in Rachrai—there are some hundred and fifty on the island. The distributions of hair and eye colour conjointly agreed very closely indeed with those found at the first survey. One third were blue-eyed, one third had fair (blond) hair. One third were of the RR (or O) blood group, one third were B or AB. In Sheffield, one half were of the RR group, one tenth were B or AB; one half had fair hair, one quarter were blue-eyed. The Sheffield observations were made on more than three hundred individuals, both for blood and for hair and eye colour. Appropriate statistical tests showed that the populations differed significantly in the distributions of the characters named.

These observations agree with a formula of connexion between the proportions of fair hair (h), pure blue eyes (e), RR blood, and B (including AB) blood, namely:

$$\frac{e}{h} = P\frac{B}{RR},$$

where P is a parameter defined by the inequality: $1 < P < 3$. This formula is derived from a consideration of the genetic nature of the characters concerned, together with their reputed order of sequence in evolution. For Rachrai, P has the value 2·1; for Sheffield it is 2·4. The classification of eyes into blue and others, and of hair colours into fair and others, is based upon published studies upon the post-natal development of the Sheffield population[3, 4], in which such a classification was found to have significance.

An account of the work outlined above will be published in full.

The Jump of Fleas

I CAN find nowhere any reference to an interesting peculiarity about the jump of fleas, though perhaps it may be common knowledge among those who train them to perform.

While I was studying in the Department of Entomology of the London School of Hygiene and Tropical Medicine, I observed a number of fleas jumping. They were contained in a petri dish and were watched under a large hand lens.

It casually occurred to me as I looked down on a stationary flea that its body was streamlined, but that the fat heavy end was its tail. Arguing from the flight of a dart, which will turn and fly point forward however it may have been thrown, I considered that a flea should travel tail first through the air.

It was an easy thing to check as fleas were all the while coming and going across my field of vision. I watched those that were landing and saw that they were in fact invariably facing the direction from which they had come.

Continuing, I noticed that a flea needs a space of about one to two inches in the air clear of obstructions for the process of turning its heavy end to the front, after jumping off. If it hits something during this part of the leap, it lands sideways and usually falls over. But if not interrupted, the leap carries the insect so that the first parts of its body to touch anything are the two back legs, which are carried in a convenient position ready for landing tail first.

If the landing place proved uncongenial, I suppose nothing could get away more quickly than a flea, already facing as it is the way it wishes to return.

Fertile Haploid Sectors by Partial Merogony in Mozaics of *Drosophila pseudo-obscura*

A STRAIN of *D. pseudo-obscura* gives a high proportion of mozaic offspring. In the majority of those obtained, only the X-chromosomes of the parents were marked and the phænotype of the mozaics consisted of a regular area showing the expected constitution and an exceptional area (usually less than half) in which the recessive genes of the paternal X were expressed. Of the fifty obtained in the first experiments forty-six were female with no suggestion of male tissue. The fact that they were completely normal as to sex suggested that the exceptional area was haploid in constitution, the complex, $1X:1A$, being known to be female. In addition, the exceptional tissue showed the greatly reduced size of bristles, eye-facets and wing-cells characteristic of haploid tissue. To test this hypothesis, a series of matings was made in which the autosomes as well as the X-chromosomes were differently marked in the two parents. Six more mozaics, all female, were obtained, and in each of these the genome of the father only was manifested in the exceptional region. This result suggests that the basis of mozaicism in these flies is some peculiarity following fertilization which permits of a division of the sperm nucleus before the fusion with the egg-nucleus becomes complete, so that a group of haploid cells is formed bearing the paternal genome which eventually form part of the adult fly. (There is also evidence that two separate sperms occasionally take part in development and also that two female pronuclei are sometimes involved, but the mozaics resulting from these contingencies are extremely rare, and are not here considered.)

The importance of these 'merogonic' mozaics lies in the opportunity they may give of studying the maturation processes of haploid germ-cells where the possibility of normal conjugation is absent. That maturation does take place under these conditions is strongly suggested by the breeding results of one of the few mozaics obtained, in which the haploid tissue formed half the abdomen. Her progeny included six patroclinous sterile sons. These were almost certainly not the result of either primary or secondary non-disjunction since our other work on non-disjunctional forms of this species shows that such males are produced in this way only with the greatest rarity. From their occurrence it is therefore inferred that the haploid germ-cells had undergone meiosis, which had resulted in the formation of some gametes containing all the autosomes but no X-chromosome. Such no-X eggs if fertilized by X-sperm would give patroclinous sons lacking a Y and therefore sterile. Moreover, these would form the only class recognizable as to their origin from the haploid or diploid tissue since, when the X as well as the autosomes was included in such gametes at maturation, they could only give rise to offspring of regular phænotype. The exceptional sons therefore probably represent about a quarter of the actual number of gametes capable of producing viable zygotes that had been elaborated from the haploid tissue of this mozaic. As in the case of triploids, there were probably many more gametes, anuploid as to their main autosomes, and hence giving inviable zygotes.

If these conclusions are substantiated by cytological observation on future cases, it will be clear that conjugation itself, or the presence of a chromosome complex capable of conjugation, though indispensable in the diploid germ-cell as a means of orderly segregation, is not, as such, a necessary step in the process of maturation. The lack of it could not therefore be plausibly invoked as an explanation of the failure of maturation to be initiated or to reach completion in species hybrids.

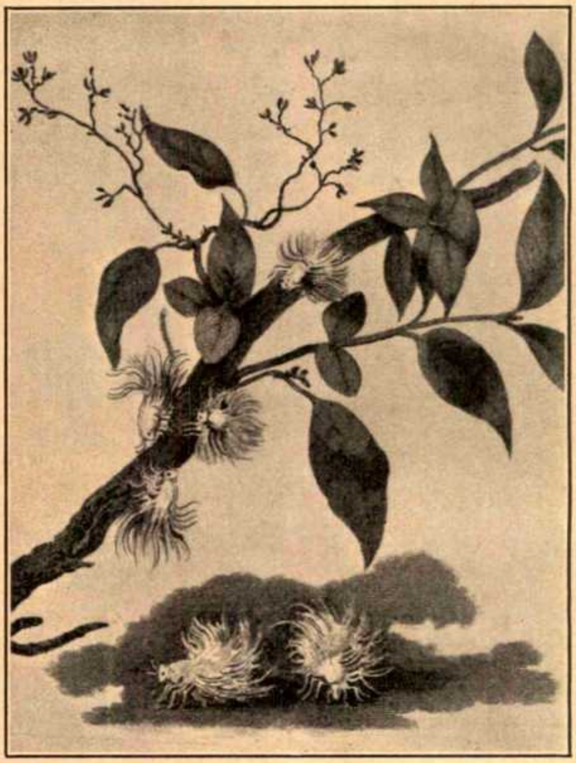
Staunton on the Wax Insect of China

SIR G. STAUNTON in his travels, "Embassy to China", published in 1797 in three volumes, describes, in vol. 1 on p. 352, a wax-producing insect that he observed in Cochin-China and not in China proper. He says, "These insects, each not much exceeding the size of the domestic fly, were of a curious structure, having pectinate appendages rising in a curve, bending towards the head, not unlike the form of the tail feathers of the common fowl, but in the opposite direction. Every part of the insect was . . . completely covered with a white powder. The particular stem, frequented by these insects, was entirely whitened by a powder . . . strewed upon it by them. The annexed engraving will convey some idea of what is here very imperfectly described. The powder was supposed to form the white wax of the East". He says further it is mixed with oils and moulded into candles.



Blanchard, in his "Coccides utiles", 1883, cites Staunton's work in his bibliography pertaining to the real Chinese wax insect, *Ericerus pela*. The engraving of Staunton, reproduced herewith, leaves no room for mistaking his insect for a scale insect, and it is surprising how Blanchard was led into such an error. Through the kindness of the British Consul-General in Chung King, I have been able to obtain some of the Chinese wax insects, which are entirely unlike the species illustrated by Staunton. It seems to me that the insect illustrated by him is probably a Cicad of the family Flatidæ, and what he saw may have been the larvæ of this unknown Cicad.

S. MAHDIHASSAN.

Chromosome Numbers in Sugarcane × Bamboo Hybrids

THE sugarcane × bamboo hybrids recently produced at this station (Venkatraman, 1937), provide material for the study of the phylogenetic relationship of the genus *Saccharum* with other grasses. The gap covered by this cross is considerably wider than in the case of the *Saccharum* × *Sorghum* hybrids[1,2], or the *Saccharum* × *Erianthus* hybrids effected in Java[3].

The female parents employed were the two Java canes: *P.O.J.* 213—an interspecific hybrid between *S. officinarum* (Black Cheribon, $2n = 80$) and *S. barberi* (Chunnee, $2n = 82$); and *P.O.J.* 2725—a rather complicated hybrid cane between a number of 'noble' types and the *S. spontaneum* (*Glagah*) of Java. The male parent was *Bambusa arundinacea* Willd., a species which is common in South India.

Root tips of *P.O.J.* 213 showed 124 chromosomes at metaphase, somatic pairing of homologous chromosomes being very apparent. Bremer has reported 62 bivalents at the reduction division of pollen mother cell of this plant. He gives $2n = 106$–107 as the chromosome number of *P.O.J.* 2725[4]. Reduction division is somewhat irregular in this cane, and like a number of other hybrid sugarcanes, it has been known to produce both diploid and haploid gametes. Pollen sterility is very high in both the canes. As the ovules, however, are fertile, these canes have been used a great deal as female parents in the breeding programme at Coimbatore. 72 chromosomes were counted in the root tips of *Bambusa arundinacea*. Root tips of five of the hybrids between *P.O.J.* 213 and *Bambusa arundinacea* showed 96–100 chromosomes and one plant of the cross *P.O.J* 2725 × *Bambusa arundinacea* examined had 90 chromosome. These numbers represent approximately the sum of the haploid numbers of the two parents.

All the *Saccharum* × bamboo hybrids so far examined differ from the *Saccharum* × *Sorghum* hybrids in the fact that whereas the chromosome numbers of the latter indicate that viable embryos are formed from fertilization of both haploid and diploid gamates[5], in the former only those derived from fertilization of haploid gametes were found to be viable. They also differ from the *Saccharum* × *Imperata* hybrids (Janaki Ammal, unpublished), where viability is limited to such embryos as are derived from the fertilization of diploid gametes only.

Pedocalic Tendencies in Soils of Southern England

THE late Dr. C. F. Marbut proposed the division of the soils of the world into two primary groups, namely, pedocals and pedalfers. Pedocals are soils developed under climates which are too dry to maintain a continuous downward movement of water to the water table. They therefore contain a horizon of accumulation of calcium carbonate (and sometimes other salts also) in the soil profile, usually in the *B* horizon. Pedalfers are soils developed under more humid climates. They are completely leached and contain no horizon of calcium carbonate accumulation. Thus the steppe and desert soils of the semi-arid and arid regions are distinguished from the podsolic and lateritic soils of the humid temperate and humid tropical climates. It has been generally accepted that the climate of Great Britain is too wet for pedocals to develop. Under free drainage conditions, therefore, horizons of secondary calcium carbonate accumulation should not occur.

Observations on the brown forest soils of Rumania, developed from calcareous lœss, were made by me, through the courtesy of Dr. Cernescu of Bucharest, in the spring of 1937. These showed calcium carbonate concretions at the base of the *B* horizon, although brown forest soils should belong to the pedalfer group. This anomalous position led me to make detailed observations of the soils in Berkshire developed from porous calcareous parent materials, since it was thought that the deposition of secondary calcium carbonate might be a function of the calcareous nature of the parent material.

Consequently, pits were dug on the Malmstone (Upper Greensand) and Calcareous Grit formations. The Malmstone soil, developed under mixed broad-leafed woodland and free drainage conditions, revealed small soft calcium carbonate concretions at a depth of 3 ft. 9 in. at the base of the *B* horizon and in the top of the *C* horizon. The soil on the Calcareous Grit, developed under very free drainage conditions, under a stand of Scots pine at least a hundred years old, revealed secondary deposition of calcium carbonate on the upper surface and in the cracks of bands of shattered rock. These occurred at a depth of 15 in. and again at 37 in.

Analytical data showed that the Malmstone profile was weakly podsolized, since some alumina had been lost from the surface horizons. Iron oxide was apparently stable, although exceptionally low in amount. The Calcareous Grit profile showed lateritic tendencies, since there was considerable loss of silica from the soil horizons. The silica-sesquioxide ratio is about 2·0 in the soil horizons and about 3·0 in the parent material. It is suggested in this connexion that all red-brown soils developed from calcareous parent material may show loss of silica from the soil horizons.

Observations on shallow downland soils near Wantage, developed from Upper Chalk, revealed secondary deposition of calcium carbonate at a depth of 6–8 in., the horizon being about 3 in. deep. The profile was calcareous to the surface, high in organic matter, with a good crumb structure, and showing the typical profile of an English rendzina. Chalk rock fragments occurred throughout the profile, but whereas these are normally humus-stained and therefore dark brown in colour in the soil, the secondary calcium carbonate, which was structureless, showed up as a white layer. This layer was very intermittent, frequently entirely absent, and in places only represented by isolated spots. I consider, however, that this profile strongly resembles the Continental *tshernosem* (steppe soil). Its shallowness is, of course, the result of erosion. In some localities the surface horizon may be completely leached of calcium carbonate and may be slightly acid in reaction, but it does not lose its steppe-like character.

Further observations have revealed secondary calcium carbonate in the parent material of Coral Rag, but not in the soil horizons derived from it. A striking example of secondary deposition of calcium carbonate was also observed in the glauconitic greensand of the Upper Greensand formation. In the upper layers of the parent material were numerous concretions of soft calcium carbonate, up to half an inch in diameter, which showed a ringlike structure in cross section. Evidently deposition had taken place around some non-calcareous material. Large amounts of calcium carbonate were also deposited in old root channels and round dead roots, showing up as a very striking white network in the greenish-grey parent material.

I suggest that secondary deposition of calcium carbonate will always occur in southern England when the parent material is calcareous. This calcium carbonate may lie within the soil itself or below it, at a variable depth in the otherwise unaltered parent material. The intermittent nature of the calcium carbonate accumulative horizon is considered to be caused by differences in moisture movements within the soil, due to small differences in the micro-relief, texture, etc. Calcium carbonate is deposited on upper rock surfaces, in cracks in the rock, in old root channels, and in the form of concretions. It is observed that these concretions are often deposited at the depth to which calcium carbonate is leached from the soil; this was also the case with most of the Rumanian soils examined.

It is of interest to note that Dr. C. F. Shaw, chief of the Californian Soil Survey, when on a visit to Great Britain for the Third International Soil Congress in 1935, observed what he described as an "apparent zone of lime accumulation" in a chalk profile in Kent. He goes on to say that this profile showed essentially the characteristics of the soils of an arid region, and ends up by asking "is there a region of arid soils in England?"

Since in England secondary deposition of calcium carbonate has not been observed in soils developed from non-calcareous parent material, I prefer to regard the phenomena in this country as a function of the calcareous nature of the parent material.

Adaptation Energy

ANIMALS continuously exposed to a uniform damaging stimulus (a drug, exposure to cold, excessive muscular exercise, etc.) at first display the symptoms of the 'alarm reaction'[1] and later pass into a resistant phase; sooner or later, however, the power of resistance is exhausted and the symptoms reappear. It has now been found that this third stage of the general adaptation syndrome may be reached more regularly and more promptly by withholding food.

Sixty female rats, two months old, were adapted to a temperature of 1° C., another group of sixty similar rats was treated with 0·2 c.c. of 4 per cent formaldehyde thrice daily, subcutaneously, while a third similar group was forced to run for 15 minutes thrice daily in 12-inch wheel cages rotated at 18–12 revolutions per minute. Six animals of each group were killed after 1, 6, 12, 24 hours and 2, 4, 6, 10, 17 and 22 days respectively. In another series of exactly parallel experiments, the rats were fasted for the last twenty-four hours before they were killed. It was found that fasting intensified the alarm reaction symptoms in the groups killed during the first forty-eight hours of treatment, but did not visibly affect those killed between the second and the tenth day. The rats killed after 17 or 22 days, and fasted, showed a return of alarm reaction symptoms; pronounced thymus and pancreas atrophy, adrenals brown and enlarged, multiple gastric ulcers and hypoglycæmia; while their non-fasted controls showed adrenals rich in lipids, less marked thymus and almost no pancreas atrophy and no gastric ulcers.

The eventual reappearance of such symptoms gives further support to the conception[2] that for adaptation the organism is dependent upon a special hitherto unrecognized type of energy. The present experiments show that while fasting is harmful during the stage of the alarm reaction when adaptation energy is not yet mobilized, and at the onset of the stage of exhaustion when adaptation energy is depleted; yet the animal in the resistant stage learns to perform adaptive functions more economically and with less dependence on the caloric energy derived from food.

The Piltdown Bone Implement

I IMAGINE that few archæologists who have made a study of palæolithic cultures, will dispute the Abbé Breuil's recent conclusion[1] that bone was much more extensively used in the earlier of these cultures than has been generally supposed. But his claim that the Piltdown bone implement owes its shaping to gnawing "by carnivores or rodents", is not, I think, likely to receive much support. The pointed end, and the butt-end, of this specimen are formed by a considerable number of facets which have every appearance of being produced by man. Some of these facets exhibit what may be termed a 'stepped' fracture, and this, I fear, has caused Breuil to conclude that animal's teeth have given rise to them.

In the experimental shaping of bone with sharp-edged flints and other stones which I carried out years ago, I found that this stepped fracture appeared frequently. A similar type of fracture is shown by certain flints, broken by some form of natural tension, in various deposits. Personally, I regard the Piltdown specimen as affording remarkably clear evidence of having been shaped by man—but I would be much interested to see the bones referred to by Breuil which have been gnawed by carnivores or rodents, and are said to mislead archæologists into believing that these bones are artefacts. I must confess that I am unfamiliar with such specimens.

Chemical Identification of Œstrone in Human Male Urine

Laqueur, Dingemanse, Hart and de Jongh[1] first reported in 1927 that œstrogenically active substances could be obtained from the urine of healthy men. The necessity arose shortly afterwards of identifying these active substances chemically. The small amounts in which these active substances occur in adult male urine has so far made this impossible. Dorfman, Gallagher and Koch[2] tried to solve the problem in 1935 by means of comparative biological studies, but such investigations merely produced indications as to the nature of the œstrogenically active substance.

On the average, adult male urine was found to contain 70 international units per litre. If one assumes a biological activity equal to that of œstrone, this represents a substance content of 7 gamma per litre. This figure makes it perfectly clear that the chemical identification of the œstrogenically active substance in male urine can only be brought to a satisfactory conclusion when large amounts of urine can be worked up. Through the intervention of the N. V. Organon-Oss, for which we take this opportunity of expressing our thanks, it has been possible for us to work up 17,000 litres of male urine. The various stages in the process are briefly described in the scheme below. Tests of the œstrogenic activity of the various fractions on castrated mice served as a guide for judging the success of the separation.

In this way we succeeded in obtaining 6 mgm. of a single crystalline substance. This proved to be identical with œstrone.

	Crystals from male urine	Œstrone
Melting point .	256–260°	257–261°
Mixed melting point ..	No depression	
Optical rotation $[\alpha]_D$ ..	+153°	+160°
Physiological activity ..	$0\cdot1\gamma=1$ I.U.	$0\cdot1\gamma=1$ I.U.

In the melting point determination practically the same crystalline form was observed as with œstrone. The identity with œstrone of one œstrogenically active substance isolated from male urine is definitely established by the above results.

Œstrone, however, is only partly responsible for the œstrogenic activity of male urine. The extract obtained according to the scheme below can be separated into ketonic and non-ketonic fractions. Only a third to a half of the œstrogenic activity passes into the ketonic fraction. We are at present occupied with the chemical identification of the non-ketonic œstrogenic fraction.

PROCESS SCHEME

Urine: extraction of the hydrolysed urine by the usual method and separation of the comb growth promoting substances.

Benzene solution: evaporated to dryness and the residue partitioned between 70 per cent alcohol and light petroleum.

Alcoholic solution: extracted with benzene after dilution with water.

Benzene solution: washed with soda solution, then with sulphuric acid and extracted with 5 per cent sodium hydroxide solution.

Alkali solution: neutralization of the alkali until practically neutral and extraction with benzene.

Benzene solution: evaporated, the residue dissolved in ether, and extracted with 0·1 *N*-sodium hydroxide solution.

Ethereal solution: treated with Girard's reagent.

Ketonic fraction: submitted to several repeated fractional sublimations in a high vacuum at less than 0·0001 mm. mercury.

125–130° Fraction: recrystallized from methyl alcohol.

Œstrone.

Points from Foregoing Letters

ON the basis of the theory of several 'time-scales', and from the fact that the equations of motion for a particle are unaltered in form when the direction of the trajectory of a particle is reversed, Prof. E. A. Milne and C. J. Whitrow conclude that all the other particles in the universe are relatively stationary, and consequently the universe is non-expanding.

Prof. V. V. Narlikar proposes a new boundary condition. It is in the tensor form and it is satisfied in the one-body problem as solved by Schwarzschild. He deduces from the condition a general result about the motion of a fluid at its surface and shows that this result implies the content of the geodesic postulate.

A discussion of isostasy leads Sir Joseph Larmor to the view that large accumulations of ice at the poles are not possible without an appreciable slowing down of the earth's daily rotation.

Prof. R. Emden points out that the energy content of the air in a room is independent of temperature and concludes that the reason why we heat our rooms in winter is not to add energy but 'entropy'.

A statistical investigation of the number of secondary cosmic rays produced in an iron-screened and unscreened Wilson cloud chamber, divided into five sections by four parallel lead plates 3 cm. thick, is described by Prof. B. Trumpy. From the results obtained he concludes that the soft components of the cosmic rays amount to about 27 per cent at the earth's surface, and that the hard components cannot be electrons.

Graphs showing the intensity of cosmic radiation at various heights near the pole of the earth's magnetic axis as compared with latitude 49° are supplied by Dr. H. Carmichael and E. G. Dymond. The results obtained both with ionization chamber and coincidence counters show that the radiation intensity is about the same, and indicate that cosmic rays of less than 3,000 M.e.v. do not exist in space, or are prevented from reaching the earth by some agency such as a solar magnetic field.

J. G. Daunt and Dr. K. Mendelssohn describe experiments indicating that the surface of a solid in contact with helium II is covered with a helium film through which the liquid is transferred to the lowest available level, the rate of transfer increasing the lower the temperature. From the amount of electrical energy which has to be supplied as current, before any apparent heating is observed in the upper part of a tube immersed in liquid helium II, A. K. Kikoin and B. G. Lasarew estimate that the thickness of the film is about 10^{-5} cm.

Dr. L. Tisza discusses a possible interpretation of the behaviour of helium II on the assumption that its viscosity is due only to the atoms in the 'excited' state, while the remaining atoms, 'condensed' in the lowest energy level, take no part in the dissipation of momentum. He concludes that a temperature gradient should arise during the flow of helium II through a capillary.

By means of a simple ultracentrifuge which dispenses with an optical system and costs only a few pounds, Prof. J. W. McBain and F. A. Leyda have been able to obtain, for the sedimentation velocity of egg albumen, values agreeing with those obtained by means of the expensive Svedberg ultracentrifuge.

Dr. J. F. Schouten describes the behaviour of a strip of variable-width sound film, such as is widely used in sound film practice, as an optical diffraction grating. The two-dimensional diffraction pattern obtained by modulating a pure tone is reproduced. Contrary to the spectrum of variable-density sound film, the spectrum of variable-width sound film contains all higher orders. The intensity along an order is mainly given by a Bessel function of that order.

From comparison of the observed heat capacities of solid carbon dioxide with those calculated from a new line observed in the Raman spectrum of that substance, S. C. Sirkar and Jagannath Gupta conclude that besides the lattice oscillations, another oscillation responsible for the origin of the new line takes place at low temperatures.

The complex rotational fine structure of the low-frequency fundamental vibrational band of methane is stated by Drs. H. A. Jahn and W. H. J. Childs to be due to a new type of perturbation involving a Coriolis coupling between this fundamental and another inactive fundamental of the molecule. A theoretical spectrum has been found which agrees well with the experimental measurements. It is pointed out that similar perturbations are to be expected in the spectra of other polyatomic molecules having a threefold or higher axis of symmetry.

Dr. T. Thomson states that positive results in the salicylaldehyde reaction of Csonka-Straub are not confined to substances possessing a methylcarbonyl (CH_3CO) group, and that therefore the enolization mechanism of the reaction propounded a short time ago by Prof. Braunstein is untenable. The reaction mechanism would appear to involve condensation through an activated methylene group and the formation of a simple alkali salt of the resulting compound.

A partial separation of an optically inactive compound (*p*-phenylene-*bis*-iminocamphor) into its optically active components, by adsorption on lactose in a Tswett column, has been observed by G. M. Henderson and Dr. H. Gordon Rule.

Prof. J. R. Partington and D. I. Coomber have obtained a value of 1·48 Debye units for the dipole moment of morpholine. The results agree with those calculated for a Sachse *Z*-form of heterocyclic ring for this compound, but the possibility of small amounts of the Sachse *U*-form cannot be excluded. The results are in agreement with those for dioxan and piperazine.

Diagrams of the structure of the 'halteres' or balancers (second pair of wings which in some insects are modified into dumb-bell shaped organs) are submitted by G. Fraenkel and J. W. S. Pringle, who disagree with Buddenbrock's conception of them as stimulation organs. The basal plate of the haltere has the structure of a trellis the resistance of which to shear is dependent upon direction, and the authors regard this, together with the end knob, as an alternating gyroscope, which gives the insect in flight fore-and-aft directional stability. They describe experiments to support this view.

Experiments carried out at Sydney by A. R. Woodhill show that *Culex fatigans* Wied. will not develop normally in water containing more than 10 gm. of salts per litre, unlike the previously reported case by Drs. Wanson and Nicolay, who reported normal development in water containing 30 gm.

C. R. Ribbands directs attention to the work of Holt, who investigated the larval gut of the mosquito during metamorphosis, and whose results do not agree with Prof. Berger's conclusion that there is a correlation between chromosome numbers and cell size.

H. J. Craufurd-Benson records the occurrence of *Solenopotes capillatus*, End. on cattle in England and Scotland, and suggests that this louse possesses a greater economic importance than has been suspected.

Dr. F. W. Dry describes various types of fibres which may succeed the coarse birth-coat hairs in Romney lambs. The immediate successors contain a large selection of kemp (coarse fibres) and after these there may be one or even more crops of secondary kemp before the first shearing when the lambs are fourteen months.

Prof. R. Prawochenski reports that the spotted wild deer imported from India, wintering in open paddocks at the Warsaw zoo, are more resistant to pneumonia than the European wild deer from the forests surrounding that city. He considers that the latter strain has been weakened by domestication and false standards of selection.

A significant relation between blood groups (as determined by serological reaction) and colour of the hair and eyes is indicated by observations made by M. A. MacConaill upon 30 Rachrai (Rathlin Island, Northern Ireland) inhabitants, and upon some 300 inhabitants of Sheffield.

Breeding experiments on the fruit fly *Drosophila pseudo-obscura* are described by Prof. F. A. E. Crew and Rowena Lamy which indicate that the basis of mozaicism structure in these flies is some peculiarity following fertilization which permits of a division of the sperm nucleus before the fusion with the egg-nucleus becomes complete. As a result, part of the adult fly has a 'haploid' constitution (with only half the usual number of chromosomes in the cell-nucleus). The authors state that the presence of a chromosome complex capable of conjugation is not a necessary step in the process of maturation.

E. K. Janaki Ammal shows that hybrids obtained by crossing Java sugarcane (female) with bamboo show that only the offspring derived from parent cells containing the basic (haploid) number of chromosomes survive. In this they differ from *Saccharum* × *Sorghum* hybrids, which give viable hybrids also from diploid parent cells (containing twice the basic haploid number of chromosomes).

The occurrence of secondarily deposited calcium carbonate concretions in or below the surface soil in Berkshire (Upper Greensand and Calcareous Grit formations) is reported by Dr. F. F. Kay. Such concretions are typical of 'pedocals' (soils developed under dry climatic conditions) hitherto not reported from England.

perhaps, arising from the feelings of a section among the natives themselves.

Rattray, while still an officer in the Service, was one of the first to fly to West Africa; and on his retirement, flying divided his interest with anthropology. He became one of the pioneers of gliding. It was his ambition that the club which he founded at Oxford should eventually become a friendly rival of the similar club at Cambridge; but this ambition is now left for others.

We regret to announce the following deaths:

Prof. A. E. Boycott, F.R.S., emeritus professor of pathology in the University of London, on May 12, aged sixty-one years.

Dr. W. Eagle Clarke, honorary supervisor of the Bird Collection and formerly keeper of the Natural History Department, Royal Scottish Museum, Edinburgh, on May 10, aged eighty-five years.

News and Views

Prof. Hans Geiger

The Council of the Physical Society has this year awarded the fifteenth Duddell Medal to Prof. Hans Geiger, of the University of Tubingen. The medal is awarded to "persons who have contributed to the advancement of knowledge by the invention or design of scientific instruments, or by the discovery of materials used in their construction". Geiger's connexion with Great Britain goes back to the days, early in this century, when he went to Manchester to study radioactivity under the direction of Lord Rutherford, and it will also be remembered that one of the early results of this happy partnership was the demonstration of the possibility of detecting a single α-particle by its electrical effect. The method in its original form was somewhat tedious and troublesome, but the invention of the 'point' or Geiger counter made possible much more rapid counting, the counting of β- as well as of α-particles and, in its more recent form, introduced by Geiger himself, even the differentiation of the effects produced by α- and β-particles. These early researches and inventions laid the foundations on which have been built the more modern elaborate and less exacting automatic methods of counting used in this field.

Geiger has also contributed notably to our knowledge of radioactive phenomena. In particular may be mentioned the experiments of Geiger and Nuttall, repeated later with greater accuracy by Geiger himself, to determine the ranges of the α-particles from various radioactive products. These experiments led to the formulation of the well-known rule connecting velocity and range, which gives a means of calculating velocities from known ranges with remarkable accuracy. But of outstanding importance are the experiments made in Manchester by Geiger and Marsden on the scattering of a beam of α-particles by thin sheets of matter. They recorded the striking observation that some of the α-particles in a beam directed on to a sheet of matter are deflected through very large angles and may even emerge on the side of incidence of the beam of α-rays. To explain the effect, Rutherford postulated the existence of large-angle scattering as the result of occasional single encounters with atoms. This led to the formulation of Rutherford's nuclear theory of atomic structure, with all its subsequent remarkable developments and far-reaching reactions on atomic theory.

Prof. E. Schrödinger and the University of Graz

Since the recent incorporation of Austria into Germany, little precise knowledge has been available as to the result of the change upon the position of some distinguished Austrian men of science. Upon inquiry we are informed that Prof. E. Schrödinger will continue to occupy the chair of theoretical physics in the University of Graz. The *Tagespost*, Graz, of March 30, publishes a letter from Prof. Schrödinger to the Senate of the University, in which he explains that he has not hitherto taken the active part expected of him in the National Socialist movement but is now glad to be reconciled to it. The last paragraph of his letter reads as follows: "Well-wishing friends who overestimate my importance consider it right that the repentant confession which I made to them should be made in public. I too belong to those who seize the outstretched hand of peace, because, sitting at my writing-desk, I have misjudged up to the last the real will and the true destiny of my land. I make this confession readily and joyfully. I believe it is spoken out of the hearts of many, and I hope in doing this to serve my country."

Dr. R. P. Linstead

Dr. R. P. Linstead, whose appointment to succeed Prof. G. M. Bennett in the chair of chemistry in the University of Sheffield, is announced on p. 943 is a distinguished younger worker in organic chemistry. Dr. Linstead is thirty-five years of age. He received his training at the City and Guilds College, Finsbury (1919–20), and at the Imperial College of Science and Technology, London (1920–25), graduating with first-class honours in chemistry in 1923. For a time he carried out research work in organic chemistry at the Imperial College, being awarded degree of Ph.D. (London) in 1926, and of D.Sc. (London) in 1929.

He received the Harrison Memorial Prize (awarded by the Chemical Society, the Institute of Chemistry, the Society of Chemical Industry and the Pharmaceutical Society) and the Meldola Medal (awarded by the Institute of Chemistry), both of which are given for research carried out by a worker less than thirty years of age. His main researches have been carried out in the field of organic chemistry, but have not been entirely confined to this field. He has published seventy-four original papers in the *Journal of the Chemical Society*, of which sixty-five are essentially on organic chemical topics. He is joint author with Prof. J. F. Thorpe of the seventh edition of Cain and Thorpe's "Synthetic Dyestuffs", and has written a number of articles for the "Dictionary of Applied Chemistry".

Mr. A. J. H. Edwards

MR. A. J. H. EDWARDS has been appointed director of the Scottish National Museum of Antiquities in succession to Dr. J. G. Callendar, who died on March 19. Mr. Edwards is the son of the late Capt. John Edwards of Dundee, one of the last of the well-known arctic whalers. He was educated at Robert Gordon's College, Aberdeen, and joined the staff of the Natural History Department of the Royal Scottish Museum in 1906. In 1912 he was appointed assistant keeper of the National Museum of Antiquities, and in 1913 went to Germany to study the preservation of antiquities with Prof. Rathgon, principal chemist to the German Government Museums. During the Great War he served in Malta, Salonika, Egypt and Palestine in the ranks and as an officer on the General List. He returned to the Museum of Antiquities in 1919 and also continued studies abroad. Mr. Edwards has visited the large museums in Norway, Sweden, Denmark and France and has contributed from time to time articles on archæological subjects which have been published in the *Proceedings of the Society of Antiquaries of Scotland* and other journals.

The Herbert Jackson Prize

THE London Midland and Scottish Railway announces that the first award of the Herbert Jackson Medal and Prize has been made to Mr. A. S. Davison, of the Crewe Chemical Laboratory, for a paper on the "Chemical and Biological Examination of Water Supplies". This medal has been struck by the Company in memory of the late Sir Herbert Jackson, and is to be awarded annually to a member of the Company's research staff for the best written account of an investigation carried out in the Company's laboratories during the year. Sir Herbert Jackson was an original member of the L.M.S. Advisory Committee on Scientific Research, on which he served from 1930 until his untimely death in 1936. He played an invaluable part in guiding the earlier work of the Committee, and above all, in encouraging the many members of the Company's scientific staff with whom he came into contact, and the directors felt that it would be appropriate to perpetuate his memory by the foundation of an annual prize for the encouragement of scientific research.

Sunspot, Magnetic Storm and Aurora on May 11

ON May 10·4 a large sunspot, crossing the sun's disk between May 4 and 17, reached the central meridian. The sunspot had originated on the sun's invisible hemisphere, and it seemed of possible significance that the longitude of the spot, 189°, differed little more than 10° from that of the large and spectroscopically active spot associated with the great magnetic storm of April 16 (NATURE, April 23, p. 721). On May 11 at 15^h 52^m U.T. a magnetic disturbance began, and this developed within a few hours into a "great" magnetic storm which, reaching a maximum towards 0^h (May 12), was accompanied by a display of the aurora borealis. At Greenwich the aurora was first seen by chance at 23^h 48^m U.T. by two of the astronomical observers, though from other reports it must have appeared some minutes before this time. The aurora, which was bright and of a deepish red colour, was described as having the form of a fan-shaped bundle of rays the apex of which extended to about 10° south of the zenith; at 0^h 10^m only faint streamers were visible. Since there was bright moonlight at the time, this aurora must have been intrinsically a very bright one, and doubtless other features would have been seen had the sky been dark. The records from the Greenwich magnetic station at Abinger, kindly communicated by the Astronomer Royal, give the following (provisional) ranges: in Declination, 80′; in Horizontal Force, 960 γ; and in Vertical Force, 420 γ. There was considerable ionospheric disturbance affecting long-distance short-wave radio transmission during the period of magnetic disturbance.

THIS magnetic storm, as pointed out by Greenwich, adds yet another member to a recognizable group of storms indicating a "magnetically" active region of the sun, extending over about 120° of longitude, which has been in operation since the beginning of 1937. If for each of the thirty-five magnetic storms recorded since then at Abinger, the longitude of the sun's central meridian at the time of the respective commencements be tabulated, it is found that in twenty-four cases (nearly 70 per cent) the solar longitudes lie between 60° and 180°; the remaining eleven storms are spread over the remaining 240° of longitude. It may also be noted that the seven "great" storms occurring during the last fifteen months correspond to solar longitudes 120° to 180°. Paradoxical though it may appear from the well-established statistical relationship between large sunspots and large magnetic storms, the distribution in longitude of large sunspots (in area greater than or equal to 500 millionths of the sun's hemisphere) over the epoch January 1937–May 1938 does not, however, favour these particular longitudes, but is more or less a random distribution. It is, of course, impossible to say how much longer this "magnetically" active region of the sun will continue to be associated with terrestrial magnetic storms, but the return of these longitudes to the sun's central meridian centred about June 8 will be observed with interest.

Discovery of a Near New Star

Dr. Otto Struve, Yerkes Observatory, reports the discovery of a new star to which the name Wolf 424 has been assigned. It is described as of the twelfth visual magnitude, and its spectrum is of the very late *M*-type. As is well known, it is possible to determine stellar distances to a fair degree of accuracy from their spectral type. The examination of the spectra of stars of known distances shows that the intensities of certain lines in their spectra vary with the true luminosity of the stars. Conversely, by studying lines in the spectra of stars, the real light output can be estimated, and this, combined with the star's apparent brightness, furnishes the necessary data for determining the distance. In the case of the new star, this method has been applied, and the spectroscopic parallax so found shows that it is probably closer to us than α Centauri. It should be pointed out, however, that there is considerable doubt about the true distance, for various reasons. Very great accuracy in determining the intensities of the lines is essential, and in addition, if, as is possible, the star is a very close unresolved binary, this would vitiate the results to some extent. There is no doubt about the star being fairly close to us, for which reason its trigonometrical parallax can be determined in about six months and its distance found by this independent method. Until this has been done, it is advisable to suspend judgment regarding Dr. Struve's conjecture that it may be the nearest star.

Recovery of Comet Gale (1927 vi)

Mr. L. E. Cunningham, at Harvard, recovered this comet in the following position: 1938 May $1^{d}\ 5^{h}\ 51{\cdot}6^{m}$ U.T.; R.A. $17^{h}\ 23{\cdot}4^{m}$; S. Decl. 13° 4′; mag. 10. It is described as diffuse without central condensation or nucleus, and there is no report of a tail. Dr. A. C. D. Crommelin has deduced the following elements:

T	1938 June 18·47 U.T.	
ϖ	208·87°	1950·0
Ω	67 50	
i	11·62	
e	0·76085	
P	10·9966	

On May 18 the moon passed near the comet. As the object is moving rapidly southward it will be difficult for observers in the northern hemisphere to see it. The following ephemeris may prove useful for those who are favourably placed for observing it:

		R.A. 1950·0		S. Decl.		
1938 May	22·0	19^{h}	4^{m}	24°	41′	8·7
	30·0	19	55	30	6	8 4
June	7·0	20	53	34	46	8 2
	15 0	21	51	37	48	8·2

Dr. R. T. A. Innes has published a long paper on this comet and found a period of 4088·8 days. He predicted perihelion passage on 1938 August 24 and also a close approach to Jupiter in August 1917 (*Mem. Brit. Astro. Assoc.*, 30, Fifth Report of the Comet Section). As the period is now known with considerable accuracy, it will be possible to examine the closeness of the approach to Jupiter in 1917.

The Evolution of Electrical Power

Dr. A. P. M. Fleming gave a Faraday lecture on "The Evolution of Electrical Power" to the Institution of Electrical Engineers on May 12. Applications of electrical power are to be found in every branch of our modern communal life, and yet few of those who make use of them have any real appreciation of the discoveries in which the modern system of electrical power had its origin, of the part which scientific research has played in making modern developments possible and of the direction in which new scientific discoveries may cause its continuous evolution to proceed. Few men have entered with success, comparable to Faraday's, into such a diversity of fields of investigation. We may well marvel that with only simple self-constructed apparatus available, he was able to formulate laws and lay down principles which have stood the test of time. Since Faraday invented the first electrical generator, numerous types of electrical generators have been developed; but the principle underlying them all is the same.

Dr. Fleming directed attention to the continuous increase in the voltages now used, to the change over from direct current to alternating current generation, to the increase in running speeds and to the enormous increase in the power output provided by single machines. These changes are linked with contemporary developments—to the introduction and improvement of the steam turbine prime mover, and to the rapid growth of central generating stations and their associated transmission and distribution networks. The electromagnetic method is not the only means of converting natural sources of energy into electrical form. The extent to which recent discoveries in the physical sciences, such as those of controlled atomic disintegration, cannot yet be forecast, but it is certain that much that is purely scientific to-day will form the basis of new industrial developments to-morrow. The spirit of Faraday is still at work, but now it works through many brains and with many hands so that who can say where it will lead?

Expedition to Greenland and the Canadian Arctic

In his Friday evening discourse at the Royal Institution on May 13, Mr. J. M. Wordie described "An Expedition to North-West Greenland and the Canadian Arctic". The objects of the expedition were in part geological, in part archæological, but in the main to investigate cosmic ray intensity near the north geomagnetic pole by means of free floating balloons. The expedition sailed from Leith at the end of June, 1937. The cosmic ray observations were undertaken at various points in West and North-West Greenland, and six flights altogether were made. Two different types of apparatus were in use, one designed by Mr. E. G. Dymond which consisted of a triple-coincidence Geiger counter set with wireless transmission of the counts and the barometric pressure, the other constructed by Dr. H. Carmichael consisting of a miniature ionization chamber with electroscope and a small camera which photographed the latter at work and at the same time recorded the temperature and atmospheric pressure. [Some of the results obtained are described by Mr. Dymond and Dr. Carmichael on p. 910 of this issue.] The greatest height reached from which a successful record was obtained was a little above 17 miles. In addition pilot balloons for testing the upper air currents were flown on twenty-eight occasions to heights in many cases of nearly 20 miles. From Thule in North-West Greenland the ship proceeded through Smith Sound to Kane Basin, and archæological investigations were made at a long abandoned Eskimo site at Buchanan Bay, Ellesmere Land, and continued in Jones Sound on North Devon Island. On the return journey the ship touched at North-East Baffin Land, which was found to be a region of long fjords which penetrate a glaciated mountain country south-westwards into hill country of low relief.

Exploring as a Career

As a rule the explorer has turned to that work as the result of chance. An adventurous spirit, often combined with financial resources, has been the introduction to exploration. Comparatively rarely, at least in Great Britain, has the explorer had the scientific training that is necessary for adequate results to be obtained from his work. A pamphlet issued by the Institute for Research, Chicago, entitled "Exploring as a Career" discusses at length the training, opportunities and possible scope of the prospective explorer. Much stress is rightly laid on personal qualities and accomplishments which an explorer should show. Though somewhat naïve in parts, the pamphlet on the whole covers the ground and incidentally directs attention to the great amount of work still awaiting true scientific investigation. A criticism that might be offered is that while a training in science is deemed essential, there is a tendency to advocate too superficial and general a course of study including even the study of public speaking, rather than a more intensive devotion to one or more branches of science which would equip the would-be explorer with the capacity to undertake specific investigations and devise new methods of research.

Native Africa and the Cinema

AN interesting experiment in the instruction of the Bantu peoples in their tribal history and traditions has been undertaken, involving the co-operation of the administration and the people themselves. Major L. A. Notcutt, director of the Bantu Educational Cinema Experiment, has made a film dealing with the history, traditions and customs of the Wasamba, who live in the mountainous region behind Tanga in Tanganyika Territory. The members of the tribe, who took part in the film, it is stated in *The Times* of May 13, were directed by Mr. L. Vickers-Haviland, District Officer of the Wasamba tribe: while the tribal authorities agreed to contribute £40 towards expenses out of the amount the tribe receives for its treasury out of taxation for the pay of native courts, officials and other tribal expenses. The subject chosen by the members of the tribe themselves was the life of Mbega, a chief who lived some three hundred years ago, and was responsible for the foundation of the tribe as it exists to-day. The film shows his life in a series of major and minor incidents, beginning with the refusal of his father, an Arab, to allow him to be killed in accordance with the custom which prescribed that children who cut the upper teeth first, and consequently were believed to be evil, should be killed. Later incidents deal with his life as a hunter and wanderer, and the story closes with his consolidation of a number of tribes, of which he becomes the supreme chief. The natives, the producer states, took the greatest interest in ensuring accuracy of detail, and definitely elected for a film of an educational rather than a 'comic' character. The main work of the Bantu Experiment is to produce films of African life for educational purposes. It is promoted by the Department of Industrial and Social Research, and has received financial assistance from the Carnegie Trustees, the Union Government of South Africa and the Governments of the two Rhodesias.

Exhibition of Antiquities from British Honduras

A COLLECTION of antiquities from the Bay Islands, British Honduras, is on view at 10 Grosvenor Place, London, S.W.1, until May 31. The collection was formed by Lord Moyne during the summer of 1937, when a brief visit was paid to the islands and more than three thousand objects, mostly of stone and pottery, were obtained from sites known to the present inhabitants. Very few traces of burials or of skeletal material were found; nor was there any other evidence to suggest that the great majority of the specimens were of a funerary character. The shallow overlying soil showed no evidence of stratification. In a note on the collection, Mr. R. W. Feacham and Mr. H. J. Braunholtz (*Man*, May 1938) point out that the objects of stone and pottery exhibited show a remarkable range of development in form and design, and that the collection as a whole is, therefore, of the greatest interest, not only archæologically, but also from the point of view of the evolution of design. Some of the specimens have features typical of the Archaic pre-Aztec culture of the Valley of Mexico, while others have characteristics indicating a period of development extending from the end of the first millennium of our era to the close of the sixteenth century, not long before the original inhabitants were exterminated by Spanish colonists. Although the absence of stratification, and of evidence of the associations of different articles one with another, makes chronological sequence and cultural grouping uncertain, the size of the collection and the period of time covered makes it possible to verify and demonstrate the development of design convincingly by providing all the links in the chain without gap. Stylistically the evidence points to strong influence at various times from such widely separated regions as Panama, Costa Rica, Honduras and Mexico. The islands may have served as a trading station in pre-Columbian times, as the Pearl Islands did on the Pacific coast, whereby influences from various quarters would have been received and redistributed.

Accessions to the British Museum (Bloomsbury)

Among recent accessions to the collections of the British Museum (Bloomsbury), reported at the May meeting of the Trustees, is a notable addition to British antiquities. Mr. F. J. Durbin has presented to the Museum the collection of finds made some ten years ago by the late Mr. W. O. Klein when excavating the Romano-British temple at Worth, near Sandwich. It was then found that the Roman temple, built of stone and erected in the second half of the first century A.D., was situated on the site of a prehistoric British shrine of Early Iron Age date, not less than one, and probably four or five centuries earlier. Among the finds were British and Roman brooches, bronze votive offerings in the form of shields, iron and bone implements in large numbers, and a considerable quantity of pottery, ranging from the Iron Age to the Roman occupation. Among antiquities from the East reported at the same time were a fantastic bronze animal figure from Iraq of the older Babylonian period (about 2000 B.C.), and a painted terra-cotta figure of a horseman, which is said to come from Luristan in Persia, and in date is thought to fall between the eighth and fourth centuries B.C. Archæologists who are concerned with western Asia will also be interested in the announcement that a diary kept by Gertrude Lowthian Bell, apparently in Arabia in 1911, has been presented to the Department of Manuscripts by her sister, Lady Richmond. The bequest to the Museum by the late Mr. T. W. Gann of jade objects, pottery and other antiquities from Central America, acquired in the course of his journeys of exploration, has now been received. The jade objects, in accordance with his desire, will be kept together as a unitary collection.

Film Demonstration of Money Movements

In view of the recent discussions on "Science and Society" in our columns, many readers will be interested to learn that Prof. M. Polanyi, professor of physical chemistry in the University of Manchester, has produced a short film entitled "An Outline of the Working of Money". The film, which runs for 25 minutes and, except in the opening section, is in diagrammatic form, is divided into five parts. It deals in turn with the circular flow of money, the actions of saving and spending, the functions of the banks, depreciation and the role of the capital goods industries, and finally the interaction of these forces affecting the working of the economic system. In the preparation of the film, simplification of ideas has of course been necessary, but it presents a most interesting venture—so far as we are aware, the first venture—in the application of methods of visual presentation to economic theory. The film was first shown to members of the Manchester Statistical Society in March, and the Society has now published the full script of the film. The film itself, which is at present only available in a silent version, was made by Science Films Limited.

A Psycho-Technical Laboratory

In *The Engineer* of May 13 is an illustrated account of the new Psycho-Technical Laboratory recently erected at Viroflay, near Versailles, for testing candidates for employment on the French State Railways. The laboratory, which is under the direction of Prof. Laugier and his assistant Mlle. Weinberg, is stated to be the most complete of its kind in France. The equipment includes two machines for neuro-muscular tests, an electro-cardiograph, an apparatus for vigilant attention tests, a sound-proof cabin for hearing tests, and an apparatus for testing the candidate's response to visual signals. The room in which the electro-cardiograph is installed is completely darkened. The heartbeats of the candidate having been recorded on a moving band of photographic paper, a powerful light is flashed into the candidate's eyes and a loud and raucous motor-horn sounded, the test being designed to determine the heart's reaction to these sudden stimuli. Tests have been carried out for some years under temporary conditions, but they were not regarded seriously by the railway administration. It being observed that candidates rejected by Prof. Laugier prove less efficient and more prone to accident, has, however, led to the erection of the laboratory.

The Institution of Electrical Engineers

The report presented at the annual general meeting on May 12 to the Institution of Electrical Engineers, shows that it is in a very flourishing condition. The membership has increased from 13,561 to 18,252 during the last ten years. The use of the Institution's premises has been granted, without charge, to a number of kindred societies in connexion with their meetings and 188 such meetings have been held during the past year. It has been arranged that as soon as a member of any class has completed fifty years of membership he will automatically cease to be asked any further subscriptions. The Council has decided that facilities to attend Institution meetings and to use the reference library should, as a gesture of good will, be offered to Chinese electrical engineering apprentices and students who, under arrangements made by the Federation of British Industries, have been given opportunities for engineering experience in Great Britain with the object of improving and fostering relations with China. The Council is also giving more active support to the Engineer's 'German Circle'. The lectures given by this Circle are in German and are by eminent German-speaking engineers. On each occasion, they will be followed by a short discussion in German. Those present can thus further their knowledge of technical German.

The following award of premiums for papers read during the session 1937–38, or accepted for publication have been awarded by the Institution of Electrical Engineers: Institution Premium to A. D. Blumlein, C. O. Browne, N. E. Davis and E. Green; Ayrton Premium to the late H. W. Clothier and B. H. Leeson and H. Leyburn; Fahie Premium to F. G. Tyack; John Hopkinson Premium to Dr. W. G. Thompson; Paris Exhibition (1881) Premium to J. S. Pickles; Overseas Premiums to Dr. V. K. Zworykin, Dr. G. A. Morton and L. E. Flory; and to Prof. B. L. Goodlet; Extra Premiums to E. T. Norris, D. J. Bolton, A. H. Davis, O. W. Humphreys, C. E. Fairburn, W. Maurice, J. N. Waite; Wireless Section Premiums to T. C. Macnamara and D. C. Birkinshaw; J. Bell, J. W. Davies and B. S. Gossling; A. J. Gill and Dr. S. Whitehead; Meter and Instrument Section Premiums to K. J. R. Wilkinson, T. A. Ledward, C. W. Hughes; Transmission Section Premiums to Dr. J. L. Miller and Dr. J. M. Thomson (Sebastian de Ferranti Premium), Dr. S. Whitehead and Mr. E. E. Hutchings.

Centralized Control of Public Lighting

In a paper read to the Institution of Electrical Engineers on May 11 by H. Purslove Barker, a full account is given of the new methods of the centralized control of public lighting and off-peak loads, by superimposed ripples. Although clock-switches have to-day reached a high pitch of mechanical perfection, they are only suitable for services where the switching routine is prearranged and invariable. There are very few applications of this kind of switching where the time of the day is the only element which should regulate the operation of a switch. For example, in street lighting the correct time to switch on and off may be determined by the incidence of fog, war or other emergency. By the aid of a central transmitter it is now possible to transmit signals by ripples of current in the distributing and feeding mains, so that one signal acting on a relay turns street lights on, another controls off-peak loads and so on. The system can operate, from a central position, an unlimited number of inexpensive relays. It appears probable that in many areas very restricted lighting will be permitted during war-time, provided that it can be instantaneously extinguished. A centralized ripple control system is now used in Paris for operating warning syrens over a large area. The same ripple that is used to start warning syrens can also be employed to call air-raid wardens in their homes by the aid of a portable relay comprising a bell which can be plugged into any socket in the network. This system of control may prove useful for many purposes in the future.

Recommendations for Seed Potatoes

Potato growers when considering the purchase of seed for next year's planting should obtain the leaflet on seed potatoes which the National Institute of Agricultural Botany, Cambridge, issues free of charge. Despite the encouragement given to potato breeding by the Ministry of Agriculture, and Scottish and Irish Departments of Agriculture for many years, more than 90 per cent of the potato acreage in Great Britain is still planted with varieties which have been on the market for more than twenty years. In most cases, newer varieties could be introduced with considerable benefit, and it is suggested that growers who are naturally reluctant to discard varieties with which they are familiar should at least try small quantities of the newer kinds so that they can test for themselves the value of the recommendations made. In the first-early class, Arran Pilot and Doon Early are suggested, while Gladstone, Redskin and Arran Signet are the recommendations for second-early or main crop potatoes. For late main crop, Dunbar Standard and Arran Cairn both produce white kidney tubers of excellent quality. A number of the older varieties are susceptible to wart disease and possess such faults as poor shape, indifferent cooking quality and proneness to second growth, but these new varieties are immune from wart disease and are only recommended after careful trial. The certificates issued by the Ministry of Agriculture and Scottish and Irish Departments of Agriculture for growing crops of potatoes, are a reliable guide to the standard of health of the purchased seed, and growers should become familiar with the different grades, that they may understand the nature of the guarantee supplied.

Commonwealth Fund Fellowships Awards

The Committee of Award of the Commonwealth Fund fellowships has made the following appointments, among others, to fellowships tenable by British graduates in American universities for the two years beginning September 1938. These fellowships are offered by the Commonwealth Fund of New York, of which Mr. Edward S. Harkness is president: Dr. G. H. Benham, University College, London, to the University of Wisconsin, in biochemistry; Dr. Bernard Cannon, University of Liverpool, to Princeton University in mathematics; A. G. Cowan, University of Glasgow, to Brookings Institution, Washington, in economics; M. W. H. Davies, University College of North Wales, Bangor, to the Massachusetts Institute of Technology, in engineering; K. J. Laidler, Trinity College, Oxford, to Princeton University, in chemistry; E. H. Lee, Gonville and Caius College, Cambridge, to Stanford University, in engineering; M. W. Lister, Oriel College, Oxford, to Harvard University, in chemistry; J. M. Meek, University of Liverpool, to the University of California, in engineering; H. B. Parry, Queens' College, Cambridge, University of Edinburgh, and Royal Veterinary College, London, to the University of Wisconsin, in veterinary science; E. R. Roberts, Imperial College of Science and Technology, London, to the University of Minnesota, in agriculture; H. B. Whittington, University of Birmingham, to Yale University, in geology; P. V. Youle, University of Sheffield, to the University of California, in physical chemistry.

The following have been appointed to fellowships tenable by candidates from the British Dominions: A. M. Acock, University of Cape Town, and Brasenose College, Oxford, to the University of California, in botany; J. S. de Wet, University of Cape Town, Balliol College, Oxford, and St. John's College, Cambridge, to the Institute for Advanced Study, Princeton, in mathematics. The following have been appointed to fellowships tenable by candidates holding appointments in Government service overseas: J. G. Crawford, University of Sydney, of the Rural Bank of New South Wales, Government of New South Wales, to Brookings Institution and Government agencies, Washington, D.C., in economics;

F. G. Forman, University of Western Australia, of the Department of Mines, Government of Western Australia, to Harvard University, in geology; L. A. Hurst, University of Cape Town, of the Department of the Interior, Government of South Africa, to the New York State Psychiatric Institute, in medicine; C. S. Plank, University of New Zealand, of the Post and Telegraph Department, Government of New Zealand, to the American Telephone and Telegraph Company, and associated companies, in engineering; Dr. V. A. Wager, Transvaal University College, and University of the Witwatersrand, of the Department of Agriculture, Government of South Africa, to the University of California, in agriculture. The following have been appointed to fellowships tenable by candidates holding appointments in the Home civil service: A. B. Cohen, Trinity College, Cambridge, of the Colonial Office; H. G. Gee, University College, and London School of Economics, University of London, of the Ministry of Labour; Robert Macdonald, University of Glasgow and Lincoln College, Oxford, of the Scottish Education Department.

Announcements

AT the general monthly meeting on May 9, Prof. W. L. Bragg was elected professor of natural philosophy in the Royal Institution, in succession to the late Lord Rutherford. Prof. Bragg, who is the son of Sir William Bragg, the Fullerian professor of chemistry and director of the Royal Institution, was recently appointed Cavendish professor of experimental physics in the University of Cambridge. He is thus the fourth Cavendish professor, following Lord Rayleigh, Sir Joseph Thomson and Lord Rutherford, who has also held the London professorship. At the same meeting Sir J. J. Thomson was re-elected honorary professor of natural philosophy and Sir James Jeans was re-elected professor of astronomy.

PROF. F. VERZÁR, professor of physiology in the University of Basel, will deliver a series of lectures on absorption in the intestine and the physiology of the adrenal cortex in the University of Oxford (Physiology Theatre, University Museum) on May 23, 24, 27, 30 and 31. Further information can be obtained from Prof. J. H. Burn, Department of Pharmacology, Oxford.

THE following appointments and promotions have recently been made in the Colonial Service: G. H. Addison, assistant curator of gardens, Straits Settlements; A. G. Bailey (agricultural officer), education officer, Kenya; R. M. Gambles (veterinary officer, Cyprus), veterinary research officer, Palestine.

AT the annual general meeting of the Institution of Civil Engineers held on May 10, Mr. W. J. E. Binnie was elected president for 1938–39 and will succeed Mr. S. B. Donkin on November 1. On the report of the judges (the president of the Institution of Civil Engineers and the president of the Royal Institute of British Architects), the Council has awarded a Charles Hawksley Prize of the value of £150 to Mr. Louis Matheson for his design of a multistoried public garage.

THE *Renaissance Française* has opened a subscription for a bust of the late Dr. Emile Roux by the sculptor Armand Bloch, to be presented to the Pasteur Institute of Paris of which Roux was director for many years.

THE eighth international congress for occupational diseases and accidents will be held at Frankfort-on-Main on September 26–30. Further information can be obtained from Ministerialrat Dr. Bauer, Unter den Linden 13, Berlin, 8.

THE fourth annual congress of medical electroradiologists will be held in the physics amphitheatre of the Paris Faculty of Medicine on October 5–8, under the presidency of Dr. Delherm. The chief subject for discussion will be neutrons and artificial radio-elements—their biological applications and therapeutic possibilities. Further information can be obtained from Dr. Morel-Kahn, 45 rue Scheffer, Paris.

THE first two volumes of Pavlov's works will be published by the Soviet Government this year in Russian, English, French and German. The first volume will contain his articles and speeches on social and political subjects and his works on circulation of the blood, and the second his observations on the physiology of digestion.

ACCORDING to statistics recently published by the Health Department of Palestine for 1936, the estimated population of Palestine at the end of June, 1936, was 1,269,952, of whom 781,789 were Arabs, 370,471 Jews and 106,473 Christians. The birth-rate was 53·14 per 1,000 among Mohammedans, 36·34 among Christians and 29 among Jews. The death-rate was 19·98 per 1,000 among Mohammedans, 12·63 among Christians and 8·83 among Jews.

VOL. 22 (1938) of the *Comptes Rendus* of the Carlsberg Laboratory is a jubilee volume in honour of the seventieth birthday of Prof. Sørensen, a portrait of whom is prefixed to it. Many papers (occupying in all 570 pages) by several well-known authorities cover a wide range of subjects, mostly of biochemical interest.

WE have received from Messers. Newton and Co., 72 Wigmore Street, W.1, their catalogue of the "Newton and Wigmore" British epidiascopes. Several types are listed, including inexpensive models for school use. The Newton projection microscope is another product supplied by the firm, the outfit ordinarily supplied being suitable for a ⅔in. objective. Messrs. Newton are also agents for the "Ampro" 16 mm. cinematograph projector, of which both sound and silent equipments are supplied.

Research Items

Classification of the Races of China

MR. CHUNGSEE H. LIU has attempted a classification of the races of China (*Zs. f. Rassenkunde*, 6, 2; 1937) in which he points out that the Chinese people are by no means a homogeneous unit as commonly supposed and examines critically the classifications of those anthropologists who have recognized this fact. Mongol, Mongoloid and Mongolian, are loose and unsatisfactory terms, and *Homo sinicus* is suggested to replace them. In the Chinese population as a whole, the physical characters are, in general terms: hair universally black, lank or coarse, straight, with almost circular cross-section; body and face hair very scanty; skin varying from yellowish to yellow-brown; eye colour light-brown; setting of eyes horizontal or oblique with epicanthic fold; cheek bones prominent, mesocephalic on the brachycephalic side; nose relatively flat with depressed nasal bones; mesorrhine; medium stature; slender or thick-set, hands and feet small. Within this general description, three types are recognized, which are distributed in accordance with the three great river-systems of China: (1) The Huangho type in the north, mainly found in the valley of the Huangho, the Liao Ho, and the Sungari River in Manchuria. This type is of high stature, dolichocephalic, leptorrhine, and of vigorous physique and robust feature. It is honest and frugal, slow but sure, chivalrous and conservative. The people speak the northern Chinese mandarin, and may be regarded as the archaic type of Chinese. (2) The Changkiang type, mostly confined to the Chang Kiang or Yangtze River valley in a favourable natural environment. This type is of medium stature, mesocephalic, mesorrhine, with light yellowish complexion. The people exhibit great literary power and ability. They speak southern Chinese mandarin with local dialects—the progressive type of the Chinese nation. (3) The Chukiang type in the Chu Kiang or Pearl River valley of southern China, with Fukien as an eastern corridor and Hainan Island beyond the sea. They are of shorter stature, brachycephalic, platyrrhine, of darker skin colour. Mentally this type is vivacious, and adventurous, quick in action and radical in thought. They speak various dialects of southern China.

Skeletal and other Remains from the Virgin Islands

REMAINS, skeletal and other, of the early inhabitants of the Virgin Islands, which had been discovered on Water Island, near St. Thomas, by Mr. A. H. Julien, were collected by Mr. J. S. Trevor in 1936. Burials of about twenty-one persons lay 2–3 ft. below the surface, in direct association with shells of the giant conch (*Strombus gigas*) and other gasteropods, small animal bones, probably those of the Indian coney (*Capromys brachyurus*), lumps of a red ochreous substance, stone implements and pottery. The skeletal remains are discussed by Dr. L. H. Dudley Buxton and the pottery by Prof. Gudmund Hatt of Copenhagen in *Man* of April 1938. As the skeletons had been reinterred, it was impossible to locate more than seven, but the occipital bone of an eighth individual was also found. These are represented by skulls, mostly incomplete, humeri, pelvic fragments, sacra, femora and calcanea, which are now in the Oxford collection. Measurements have been made by Dr. Buxton, who regards the material as too scanty to give anything but the most tentative results. In 1492, Dr. Charlotte Gower has concluded, there were at least three populations in the West Indies, possessing distinct cultures. These were the Caribs, the Ciboney and the Tains and/or Ygneri. Owing to the lack of any description of the physical characters of the aborigines for comparison, the present material admits of the addition of nothing substantial in the way of argument from the skulls. None of them displays artificial deformation, which is common in the Carib, but is said to be absent in the Ciboney. There is no high cephalic index, though the general tendency of the West Indian skulls is towards brachycephaly. High nasal indices and marked prognathism suggest negroid characteristics, but a secondary interment after the introduction of negro slaves seems unlikely. In his discussion of the pottery, Prof. Hatt affirms that the vessels are of pre-Columbian Indian origin. In form and ornament, the pottery resembles that found previously in St. Thomas and St. Croix. It is probably earlier than the Carib invasion and, therefore, Ignerian, that is, Arawak.

Vascular Anatomy as a Taxonomic Tool

THIS subject has received a very thorough treatment by P. A. Vestal (*Phil. J. Sci.*, 64, No. 3, November 1937) in connexion with the Hypericaceæ and Guttiferæ and allied families. The vascular characters that proved most significant were the dimensions of the vessels, the nature of their perforations and of the pittings upon their walls, the pitting and dimensions of fibre tracheids and the characters of the rays, particularly the uni-seriate rays. It is concluded that the groups studied fit very well with the taxonomic groups of Wettstein, the Parietales and Guttiferales, and that the anatomical evidence is more in favour of this author's treatment of these families or of their arrangement by Engler and Prantl than with their treatment by Hutchinson. The anatomical criteria found of value in this study agree very well with those of which the significance is underlined in a more general study of the same problem by L. Chalk (*Ann. Bot.*, N.S., 1, 409–428), but the latter author finds Hutchinson's arrangement of the Archichlamydeæ more in agreement with the evidence from anatomy than that of Engler.

Effects of Radiation on Polypore Fungi

THE results of a detailed investigation into the action of ultra-violet rays, X-rays, radium and sunlight upon three polypore fungi, formed the subject of the presidential address by Prof. S. R. Bose to the Botanical Society of India on January 6, 1938 (*J. Ind. Bot. Soc.*, 17, No. 1, 5; 1938). *Polyporus ostreiformis*, *Polystictus leoninus* and *Trametes cingulata* were the three species concerned, and the experiments were made with plate cultures upon malt extract agar. Ultra-violet rays and excessive direct sunlight diminished for a time the fertility of all three fungi, and in some cases even death ensued. Both hard and soft X-rays were studied; small doses gave slight injury, from which the organisms recovered quickly, whilst heavy doses totally suppressed sporophore formation. Conidia and chlamydospores, however, remained almost unaffected. No effect of X-rays in promoting saltations, or mutations in culture, was observed. Treatment of the three polypores with large doses of radium damaged the vegetative hyphæ and delayed the formation of fruit bodies, but subcultures recovered quickly. It is a notable fact that the three species mentioned will not fruit in darkness, so evidently they can tolerate, if not enjoy, the amounts of radiation present under natural conditions.

Action of Ammonia on Mercurous Chloride

ALTHOUGH the blackening resulting from the action of ammonia on mercurous chloride is now usually regarded as due to finely divided mercury, the nature of the other product has been the subject of discussion. H. R. Frecke and M. C. Sneed (*J. Amer. Chem. Soc.*, 60, 518; 1938) have shown that the course of the reaction is influenced by the concentration of aqueous ammonia (ammonium hydroxide) used, as well as by the time of reaction. The end-products with concentrated ammonia are a grey precipitate of the composition ($Hg + NH_2.HgCl$) and the water-soluble fusible compound $HgCl_2.2NH_3$. The latter on dilution partially decomposes into NH_2HgCl and ammonium chloride: $HgCl_2.2NH_3 \rightleftharpoons NH_2HgCl + NH_4Cl$, so that the total reaction would be: $Hg_2Cl_2 + 2NH_4OH = Hg + NH_2HgCl + NH_4Cl + 2H_2O$. In the case of dilute ammonium hydroxide, however, the speed of reaction is sufficiently slow to permit the identification of the intermediate products, namely, mercurous oxide (Hg_2O)—which does not amalgamate gold sheet—and ammonium chloride, which further react to produce metallic mercury and NH_2HgCl: $Hg_2O + NH_4Cl = NH_2HgCl + Hg + H_2O$. The authors consider that under ordinary conditions the reaction between mercurous chloride and ammonium hydroxide is best represented by the equation: $2Hg_2Cl_2 + 4NH_4OH = [Hg + Hg_2O + NH_2HgCl] + 3NH_4Cl + 3H_2O$.

Theory of Liquids

IN a series of papers published in Indian journals between 1934 and 1936 a theory of liquids was developed by Dr. T. S. Wheeler, who obtained formulæ for many liquid properties, such as surface tension, viscosity and heat of evaporation, in terms of interatomic forces of the Lennard-Jones type. A collected account of this work has now been published (*Trans. Nat. Inst. Sci. India*, 1, 333; 1938). The theory is based on simple physical ideas and uses only elementary mathematics. A liquid is regarded as composed of a number of force centres, each of which vibrates within a spherical space kept free from other molecules by its thermal motion, and the translational motion is assumed to be small compared with the vibrational motion. A number of formulæ have been derived relating certain properties of a liquid with one another, and when the Lennard-Jones force constants are substituted in them they give numerical results in fair agreement with experimental values. The method employs a number of simplifying assumptions such that the molecules of a liquid are uniformly distributed round any one, that within the free spherical volume in which each molecule moves there is no field of force, and that the formulæ of the kinetic theory of gases may be applied. There is no discussion of entropy or of free energy, on which alone calculations of vapour pressures can rigorously be based. None the less the paper gives a picture of a liquid which, while oversimplified, may help some workers on this subject to visualize liquid properties more easily.

Principles of Plant Design in Electrolysis

IN a paper on electrolysis discussed at a joint meeting of the Institutions of Electrical and Chemical Engineers on April 27, Dr. H. J. T. Ellingham concludes that although the principles on which the design and operation of plant for electrolysis depend are at least as simple and clear-cut as those for most other kinds of industrial process, their successful application requires close co-operation between the chemical engineer and the electrical engineer. This would ensure the co-ordination of the electrical and chemical factors in any particular problem in the most complete and appropriate manner. The paper sets out and correlates the relative electrochemical principles. Electrolytic processes may be carried out in order to obtain products such as metals, alkalis, oxygen and hydrogen, and various salts, which are to be marketed as such; but certain of these processes may also be worked as part of some other industry, as, for example, electroplating in the motor-car industry, alkali and chlorine in the manufacture of paper, and chlorates in the match industry. For many processes, electrolytic cells of various types have been patented, and units of standard size and output can be purchased from the respective manufacturers, for example, cells for the production of oxygen and hydrogen, or alkali and chlorine, and plant and chemicals for electroplating. Some electrolytic processes depend for their efficient operation on continuous working during day and night. These provide a very steady and continuous load for a power station. Many types of electrolytic operation are worked intermittently and a few, like oxygen and hydrogen, can be operated for irregular periods without much loss of efficiency. It would be advisable to arrange that these loads should be operated during 'off-peak' loads in conjunction with other intermittent electrical processes, so as to effect economies for both the chemical and electrical industries by securing a high load factor.

Spectrohelioscope with a Vibrating Slit Mechanism

MR. F. J. SELLERS, director of the Solar Section, British Astronomical Association, has described his own construction of a spectrohelioscope, involving certain departures from the standard type (*J. Brit. Astro. Assoc.*, 48, 6; April 1938). Mr. Sellers considered that oscillating slits would be more satisfactory than rotating prisms, and the spring-vibrating system is very simply operated by means of an electric contact-breaker, like an electric bell. The optical reversal occasioned by the collimating mirrors necessitates that the second slit should move in opposite phase to the first and remain parallel to it. A full description with a diagram is given of the various parts. Any amateur would be able to construct the various fittings required for the apparatus. It is interesting to notice that ordinary bell-battery dry cells operate the contact-breaker, and that these have been in use for eighteen months without serious signs of depreciation. Indeed, the whole apparatus has not given a moment's trouble since it was first tried in October 1936.

Roman Britain

RECENT study of Roman Britain has profited on the whole more perhaps than any other branch of archæological research in Great Britain by co-operation between the national administrative body, the Office of Works, with its statutory powers, the local authority, and the local archæological society, representing expert knowledge and instructed interest. A conspicuous example of the success of such co-operation is afforded by the excavation of the Forum of Roman Leicester, of which a part, the so-called Old Jewry Wall, was handed over to the custody of the Office of Works so long ago as 1920, but of which it became possible to ascertain the true character only after the site had been acquired by the Corporation in 1935 for public baths. Thanks to an enlightened, but economical, solution of the financial problem on the part of the authority, public and private funds were able to combine to carry out a thorough examination of the site in 1936 and 1937 under the direction of Miss Kathleen Kenyon, with the result that by a further public-spirited act on the part of the Corporation, Leicester now possesses one of the most striking and remarkable monuments of Roman Britain still surviving.

The character and history of the complex of which the Old Jewry Wall had been the only visible relic since the Middle Ages, though not completely revealed, especially in regard to some of the more interesting features, until the excavations of 1937, was apparent in the more important essentials when the work of 1936 was brought to a close. An account of the results of the first season's work has been published by Miss Kenyon recently (*Trans. Leicester Lit. Phil. Soc.*, 1936–37).

The earliest inhabitants of the portion of the site excavated in 1936 would appear to have been slightly Romanized Celts of the Belgic tribes; but as none of the pottery then found dated from before A.D. 40, it seemed likely that they had been attracted, whence is not known, by the legionary camp established here on the line of the Roman advance. In the following period, a town was laid out on Roman lines, some of the roads constructed passing over the pits of the first occupants. For the next fifty years or so, the houses along this road were built of wood with clay-filled walls and mainly occupied by the descendants of the original tribesmen. They were becoming gradually more Romanized. Then about A.D. 120 Leicester shared in the movement for setting up grandiose municipal buildings over Roman Britain. The area was cleared and the whole laid out as a basilica and forum in the usual Roman style and on a scale which compares with any in Britain. Though the later history is obscure, the site was undoubtedly occupied in the third and fourth centuries; but towards the close of the period, the neglected state of the roads points to the time when municipal organization was breaking down and trade and other civilized activities were failing. Thereafter, more especially with the Saxon occupation, the buildings served merely as quarries, the incorporation of the wall, which survived to modern times, in an early Saxon church probably being responsible for its preservation.

A further example of the valuable results which may accrue from such co-operation between public authorities and private bodies is afforded by recent work of the Letchworth Natural History and Antiquarian Society, for a report of which we are indebted to Mr. W. Percival Westell, honorary curator of the Letchworth Museum. The Hitchin Rural District Council in carrying out a housing scheme proposed to erect cottages partly on the site of the outer bailey of Great Wymondley Castle, near Hitchin. The scheme was approved by the Office of Works, provided that it were carried out under expert archæological supervision. This supervision was undertaken at the request of the Office of Works by the Letchworth Society. Unfortunately a drainage trench, which had yielded Romano-British pottery, had already been filled in before representatives of the Society arrived, nor could it be reopened; but a series of trenches was opened as near the line as possible. From these much interesting material was obtained. A large number of bases and sherds of Romano-British pottery was found, together with bones and teeth, tiles, nails and oyster shells. In one trench at a depth of 1 ft. 6 in. there was discovered a flint and rubble floor, measuring six feet in width and twenty-four feet in length, while at the south-west corner was a rubbish pit. An extension of the floor, but with much smaller flints, was found at right angles and at a depth of 2 ft. 6 in. This was 1 ft. 6 in. below the old turf level, which was plainly visible at a depth of 1 ft. below the present surface. In another trench was a circular layer of flints, within which was a rammed floor. This was without flints, and overlying it were many pieces of fired daub and cut pieces of wattle of elm wood. This would appear to be the site of a primitive oval thatched hut, probably for storage, and, it may be, pre-Roman. No pottery or other objects were found within the circle. The diameter of the circle of flints is 8 ft. The pottery found is of the first and second centuries A.D. and consists of coarse ware cooking pots, grey ware bowls, dishes and vases, and black ware. A few fragments only of Samian ware were found.

The activities of the Society in other parts of Hertfordshire have produced some interesting finds. At Baldock, an exceptionally rich region, two full-length skeletons, a quantity of pottery and building materials, as well as parts of British and Roman querns have been found. From South Road came a perfect large coarse ware brown urn, containing a heavy cremation with a Samian dish clamped at the side. This rested on the skeleton of a horse; and was found at a depth of three feet. A number of Romano-British finds are also recorded from Ashwell, Hitchin and Letchworth itself. The last named, the remains of four Romano-British pottery vessels, indicate that the rectangular pit-dwellings, such as recently were recorded at Hawthorn Hill, Letchworth, extended still farther to the north-west.

The excavation of the hill-fort known as The Caburn, near Lewes, which was described by Dr. A. E. Wilson before the Society of Antiquaries of London on February 10, was especially interesting for the evidence which it furnished of successive occupations. Pottery found in the old turf beneath the early rampart pointed to an occupation of an undefended village settlement dating at about 500 B.C. Then at about 250 B.C. the top of the hill was enclosed by a single rampart and ditch which are still visible as an inner work. At about 50 B.C. an extensive and ambitious scheme of refortification was undertaken, which included an outer rampart and ditch. This, however, seems not to have been completed. A complete rebuilding took place in the year, approximately, A.D. 50, when a full outer rampart and ditch were constructed. The site was then neglected for a thousand years, until in the eleventh century some refortification took place. The excavations have been carried out by Dr. Wilson on behalf of the Brighton and Hove Archæological Society, with the assistance of Dr. Cecil Curwen and Mr. G. P. Burstow.

An account with photographs of the recently discovered western postern for pedestrians of the Newport Arch at Lincoln is given by Mr. F. T. Baker in *Discovery* of February. This arch, famous for having been in uninterrupted use since its erection probably in the second century A.D., was the northern gateway of the Roman occupation. The surviving portion consists of the southern face of the main arch and an eastern postern; but the demolition last autumn of a building abutting on the western side of the arch brought to light the spring of an arch, which confirmed previous conjecture that there had also been a postern for pedestrians on the western side. It is evident that barrack rooms, or chambers for some such purpose surmounted the arch. The discovery of a portion of the Roman city wall in the course of the work indicates that this met the structure of the gate at approximately the centre, and not flush with the south or north face as previously thought. The exterior angle, possibly, may have been filled by a bastion.

The Rockefeller Foundation*

Barriers to International Aims

FROM the beginning of its activities twenty-five years ago the Rockefeller Foundation has been guided by the objective written into its charter: "The well-being of mankind *throughout the world*". In accordance with this purpose the aim of the trustees has been to maintain the work of the Foundation on an international plane without consideration of flags or political doctrines or creeds or sects. Particularly in a programme based on the advancement of knowledge it is imperative to disregard the geographical boundaries which arbitrarily and often unhappily divide the earth into a patchwork of senseless antagonisms. For in the last analysis knowledge cannot be nationalized. No successful embargoes can be maintained against the export or import of ideas. Whether new conceptions in atomic physics come from Copenhagen or from Cambridge, England; whether the cure for cancer is developed in New Haven or in Berlin; whether it is a Russian or an Italian or an American who takes the next step forward in mankind's struggle with virus diseases—we are all of us, under whatever flag, the joint beneficiaries of the intellectual property of the race. In all the clash of competing nationalisms there is here an underlying principle of unity: the single aim and language of science in the discovery of truth. It is this principle which challenges the twentieth century with the conception of civilization as a co-operative achievement and with the ideal of intellectual capital as an international possession.

A foundation, therefore, whose aim is to assist in pushing out the boundaries of knowledge must necessarily work wherever the best tools are to be found. In its search for high talent and promising opportunities it must assume that frontiers are not the forbidding barriers they pretend to be.

This ideal, which for more than two decades the Rockefeller Foundation has consistently attempted to follow, has in recent years encountered serious difficulties. And these difficulties are increasing. Objective scholarship is possible only where thought is free—and freedom can exist only where there is tolerance, only where there are no "Keep Out" signs against the inquisitive and questioning mind. Disinterested research cannot survive in an atmosphere of compulsion and repression. It withers under the efforts of Governments to impose uniform ideologies and to circumscribe in the interests of a dominant regime the area of intellectual liberty. Particularly in the broad range of subjects covered by the social sciences, and in the humanities as well, the world has recently witnessed in several countries the progressive disintegration of creative scholarship.

This phenomenon has naturally affected the programme of the Foundation. In some fields it is now profitless to go where we formerly went. We find ourselves stopped at some frontiers—not because the frontiers have any greater geographical significance than they had a few years ago, but because behind them the search for truth by eager and sceptical minds has been made impossible.

Some twenty years ago in a Central American city a revolution developed while the Foundation was engaged in a study of yellow fever control measures. Dr. Emmett Vaughn, who was in charge of the work, determined to continue his research. Every morning with a flag of truce he crawled through the barricades to collect his mosquitos on one side of the fighting line, and in the afternoon he crawled back again to gather up his specimens on the other side. He was molested by neither army. Both sides thought him somewhat crazy—a man who, when great issues of human destiny were being fought out, spent his time catching mosquitos. To-day in that Central American country the revolution has been largely forgotten, but Dr. Vaughn is remembered as the man who helped to stamp out an age-long pestilence.

The Rockefeller Foundations likes to think of this incident as an example of what its approach to the welfare of mankind should be. But occasionally aggressive action by the fighting lines makes impossible even the gathering of mosquitos!

Alchemy under James IV of Scotland *

JAMES IV of Scotland was one of the most intelligent princes in Europe at the beginning of the sixteenth century. He had an active and inquiring mind, and sought to extend his knowledge by observation and experiment. His interests included medicine and surgery, physiology, alchemy, and even psychology. Thus, in 1493, he tried to determine by a direct experiment the nature of that "primitive tongue" which Ben Jonson, at a later day and in jocular mood, supposed to be High Dutch. "The king gart [caused] tak ane dum woman and pat hir in Inchekeytht [island]", wrote Lindesay of Pitscottie, "and gaif hir tua young bairnes, and gart furnische them of meit, drink, fyre and candell, claithis [clothes], witht all uther kynd of necessaris, desyrand to knaw quhat langage thir bairnes wald speik quhene they came to lauchfull aige. Sum sayis they spak goode hebrew bot as to my self I knaw not."

James's excursions into alchemy were probably determined by his interest in medicine, because of the potent medicinal and rejuvenating virtues which were ascribed to the Philosopher's Stone. His chief associate in a prolonged series of alchemical experiments was a certain John Damian, an ingenious and personable Italian or Frenchman. Under Damian's inspiration and direction, James established Scotland's first research laboratory in Stirling Castle.

James provided his alchemist with an emolument and the necessary leisure for research by creating him Abbot of Tungland, in Galloway. The new ecclesiastical dignitary preferred the smells of his laboratory to the odour of sanctity, and feared the effect of the laboratory smoke upon his costly religious vestments.

The accounts of the Lord High Treasurer of Scotland from 1501 to 1513 throw some interesting light upon the nature and cost of the materials which Damian and his associates used in their attempts to prepare the *quinta essencia* (Philosopher's Stone, or Elixir of Life). Among them were gold, silver, quicksilver, aqua vitæ, saltpetre, sal ammoniac, litharge, salt and sugar. The prices of apparatus, the wages of the laboratory attendants, and even the cost of the alchemist's attire, are detailed in the Treasurer's records.

Three kinds of aqua vitæ, or whisky, are indicated by the adjectives "small", "ordinary" and "thrice-drawn". Although in the strange Scotland of James IV whisky must have been a rare drug reserved mainly for medicinal purposes, the Abbot of Tungland and his collaborators in the Great Work were able to secure and find uses for surprisingly large amounts.

Among occasional visitors to the Stirling laboratory was one Broun, a master "potingair of Sanctandrois". Skilled in the distillation of "waters" perfumed with essential oils, and also in the primitive sugar "potingry" of those times, this worthy apothecary was the unconscious prototype of the St. Andrews chemists of a later age.

The Abbot's attempts to achieve the Stone were interrupted in 1507, as a result of another of his spectacular activities. In the quaint language of Bishop Lesley: "This Abbott tuik in hand to flie with wingis; and to that effect he causet mak ane pair of wingis of fedderis". Equipped with these movable feathered wings, he took off from the lofty battlements of Stirling Castle for a flight to Paris; "bot shortlie he fell to the ground and brak his thee bane". Nothing daunted, the courageous experimenter ascribed his downfall "to that thair was sum hen fedderis in the wingis", which yearned and coveted the midden and not the skies: if the wings had been made entirely of eagles' feathers, they would have exerted a natural tendency to soar into the heavens!

The alchemical experiments in Stirling Castle were continued until 1513, when the interest of the Scottish crown in alchemy came to an untimely end with the death of James IV upon the tragic field of Flodden. A century and a half later this interest in science found a rebirth in two of James's distant descendants—Prince Rupert of Bavaria and King Charles II.

* Abstract of a lecture delivered to the Society for the Study of Alchemy and Early Chemistry on May 11, at the British Academy, Burlington Gardens, London, W.1, by Prof. John Read, F.R.S.

Aeronautical Research in Australia

THE growth of civil aviation and the necessity for increased attention to Air Force requirements led the Australian Government last year, at the instance of the Council for Scientific and Industrial Research, to invite Mr. H. E. Wimperis, retiring director of research to the Air Ministry, to visit the Commonwealth to examine the existing situation with a view to the inauguration of aeronautical research. His report was presented in December last and its recommendations have been generally approved by Cabinet.

It was desired that such facilities as might be provided for aero-engine work should be extended to cover automobile engines: hence the first recommendation provides for an engineering research establishment at a suitable centre (almost certainly Melbourne), equipped for experimental work in wind tunnels, for engine tests for both aircraft and automobile use, and for physical tests of aircraft instruments and other apparatus. The laboratory will be administered by the Council for Scientific and Industrial Research, the programme of research, under a civilian superintendent, being supervised by an Australian Aeronautical Research Committee with an independent chairman. Its membership will include official representatives of the military and civil aviation departments, of meteorological services and radio communications, together with non-official members having special scientific and technical qualifications.

So far as practicable, use will be made of existing facilities at universities and in defence laboratories, the former being encouraged to undertake approved investigations in aeronautics for which they are fitted. It is proposed to create a chair and department of aeronautics (probably in the University of Sydney) to ensure a supply of trained personnel for military and civil aviation and for aeronautical construction. A readership in meteorology will also be established.

The Research Committee will form sub-committees to deal with aerodynamics; power plant; navigation and meteorology; materials; accidents; and air inventions. It will also be required to investigate the use of Australian-produced materials and processes in aircraft construction; and it will maintain a general information service.

On the automobile side it is proposed to set up an Industrial Research Committee to assist the Council with advice on a programme of research and to seek the co-operation of the industry in making provision for the carrying out of it.

It will be some considerable time before the projected laboratory is completed, but a start will be made in the current financial year. Provision is being sought for £143,000 to cover capital expenditure, and the estimated annual maintenance cost is put at £12,000.

Electrical Interference with Radio Reception

It has been well known for some years that a large proportion of electrical apparatus and plant, of both a commercial and domestic character, produces discontinuous electrical currents, which can result in interference with radio reception over a wide range of frequencies. In view of the widespread use of broadcast receivers in everyday life, it is very much in the public interest that all possible steps should be taken to mitigate the results of such interference. In Nature of August 1, 1936, reference was made to the work of a joint committee representative of all sections of the electrical and radio industries in the study of this problem. Following the report of this committee, a number of other committees have been at work under the auspices of the British Standards Institution compiling specifications of components which may be fitted to electrical ap-aratus and to radio receivers with the object of ducing the nuisance of interference to a minimum. ncurrently with the operation of these committees, e Post Office on one hand and the British Electrical d Allied Industries Research Association on the her, have been carrying out investigations on a mprehensive scale.

The results of such investigations were summarized a meeting of the Wireless Section of the Institution Electrical Engineers on April 6, when a paper was ad by Mr. A. J. Gill (of the Post Office) and Dr. S. hitehead (of the Electrical Research Association) nder the title "Electrical Interference with Radio ception". The paper described the method of essment of the interference to radio reception by ctrical equipment, and the degree to which such erference must be reduced to permit satisfactory vice. Various methods of measuring the inter-ence have been developed in different countries d the most reliable of these have been compared th the view of securing uniformity of interpretation the results.

With the aid of such apparatus, a study has been de of the interference produced under typically ctical conditions from such electrical sources as lley-buses, high-voltage overhead power lines, high-quency medical apparatus and surgical equipment, ctric lifts, telegraph and telephone plant, domestic pliances and the ignition systems of motor-cars. has been found that while in some cases the inter-nce is experienced by direct radiation from the ce, it is more common for the interfering voltages et up currents in the electrical supply network, from which the mains at the receiving station radiate locally to the receiving aerial. Following this appreciation of the nature and magnitude of the source of the interference, a detailed study has been made of methods of suppression to the level required to give satisfactory reception. Where possible, it is naturally best to suppress the interference at its source; but where this is either impracticable or unduly expensive, it is necessary to take steps to improve conditions at the receiver itself. Very effective methods of suppression have been worked out in some detail and some typical results of applying these are described in the paper. It is by the continued friendly co-operation between the electrical and radio industries that continued progress is to be anticipated as the methods of suppression and mitigation now available come into widespread use.

One of the methods adopted by the Post Office in dealing with this matter has been by co-operation with the ordinary broadcast listener in investigating complaints of interference brought to the notice of this Department. The number of such complaints brought to the attention of the Post Office has increased from some 10,000 in 1931 to nearly 50,000 in 1937. To deal with this problem, a full-time staff of about 250 are employed, and these have been trained by special courses of instruction. The equipment available to this staff comprises 110 motor-vans, each supplied with an interference locator, portable wireless receiving set, screened leads and a number of suppression components for demonstration purposes. The work of this staff has already produced a great amelioration in the conditions of broadcast reception. It is interesting to note that in some cases the broadcast listener is himself the cause of much of the interference of which he complains; for although it may not be usual in any one household to listen to broadcast programmes at the same time as the vacuum cleaner or electrically driven sewing machine is in use, these items may cause considerable interference to neighbouring listeners. Perhaps the time is not far distant when the man in the street may insist that all new domestic electrical appliances which he purchases will have been certified as 'interference free'.

The paper, to which reference was made above, concludes with an extensive bibliography, which indicates the large amount of scientific and technical work which has been devoted to this subject.

Science News a Century Ago

Magnetism at Low Temperatures

On May 17, 1838, Faraday wrote in his Diary: "Graham has lent me Thilorier's Carb. acid apparatus and I have been experimenting with it in cooling metals and ascertaining their relation to Magnetism. The metals were in pieces, kept a while in the mixture of Ether and C.A. with solid C.A. in it, and moved either by platina wires or by wooden tongs. The temperature according to Thilorier would be about 112° below 0° of Fahrenheit." With these arrangements, Faraday proceeded to test the magnetic properties of a large number of metals at the low temperature obtained, but without exception "these gave no deflection by a double astatic needle that was exceedingly sensible to the smallest particle of iron or nickel". The experiments were in continuance of some he had made in December 1835, and were the outcome of an idea he had at the time that all metals might acquire magnetic properties at low temperatures similar to those of iron. In 1835, the lowest temperature he had been able to reach was about − 70° Fahrenheit.

Thilorier had recently developed in France his apparatus for liquefying and afterwards solidifying carbon dioxide; and he had published his important observation of the value of a mixture of solid carbon dioxide and ether as a refrigerant. Faraday, interested in the attainment of low temperatures, was quick to see the advantages of the new method. He used the mixtures of carbon dioxide and ether afterwards in experiments on the liquefaction of gases; but it is interesting to notice that his first thought, on hearing that a temperature lower than any he had previously used could be obtained, was to test his theories of magnetism by it.

The "Graham" from whom the apparatus was borrowed was almost certainly Thomas Graham, the chemist.

Magnetic Observations at Greenwich

On May 21, 1838, at the Royal Observatory, Greenwich, as Airy records, "a magnet was suspended for the first time, Mr. Baily and Lieut. [afterwards Sir William] Denison being present". Airy had submitted a proposal for a magnetic observatory to the Admiralty two years before, and during the course of 1837–38 the observatory, a wooden building, had been erected in the form of a four-armed cross with equal arms, one axis being in the magnetic meridian. In 1840, the Magnetical and Meteorological Department was formed with James Glaisher, F.R.S. (1809–1903) as head. Glaisher held this position for thirty-four years. He was one of the first to adopt the photographic self-recording instruments of Charles Brookes (1804–79), and in 1850 he founded the Royal Meteorological Society, of which he was the secretary from 1850 until 1872. He was also well known for his balloon ascents for scientific purposes made during 1862–69 on behalf of the British Association Committee. On one of these, made on September 5, 1862, with Coxwell, he reached a height of seven miles.

Launch of the S.S. *British Queen*

At Limehouse, on May 24, 1838, Curling and Young, the shipbuilders, launched the Atlantic steamship *British Queen*, then the largest vessel of her kind in the world. She was constructed for th British and North American Steam Navigation Company. of which the American lawyer, Junius Smit (1780–1853), was the founder, and the famou African explorer, Macgregor Laird (1808–61), was th secretary. She was 275 ft. long from figurehead t taffrail, and 64 ft. wide over the paddle boxes. Afte her launch, she was sailed to the Clyde, where he engines of 500 horse-power were fitted by Rober Napier. She was one of the first vessels fitted wit surface condensers instead of jet condensers, and wa able to use fresh water in her boilers. Her first trans Atlantic voyage was made in July 1839, when sh crossed from Portsmouth to New York in 15½ days She returned to England in August, and during 183 made two more double passages. She made fiv double crossings in 1840 and one in 1841, after whic she was sold to the Belgian Government. She wa somewhat larger than her famous rival the *Grea Western*, which, however, proved a slightly faste vessel.

Supply of Rubber from India

On May 26, 1838, at a meeting of the Asiati Society, Dr. Royle, the secretary, read a pape entitled "On Caoutchouc or Indian Rubber". H stated that caoutchouc was known to the Peruvians and to the Chinese in early times. Condamine firs noticed it, in his voyage down the River Amazon i 1743, by the name *cachuchu*. Dr. Priestley afterward mentioned it as a rubber-out of pencil marks. D Royle said that, a few years before, about five ton were imported; now 500 tons are annually brough into London and Liverpool alone, and the quantit is daily increasing.

Caoutchouc is produced by numerous trees an shrubs of the natural families of the Euphorbiace Apocynaceæ, Asclepiadaceæ and Moraceæ in tropic parts of the globe, where high temperature is combined with moisture. It is imported from Para ar other places in South America, Vera Cruz, Sier Leone, Java, Penang and Singapore. It is also pr duced in India, being obtained from *Ficus elasti* a native of the forests of Silhet and Lower Assa It was of excellent quality, and feeling assur that the tree must be abundant and knowi that it could be easily grown in every part of In he (Dr. Royle) addressed letters on the subje to the societies and individuals in Calcutta. T replies proved that the supply of caoutchouc w inexhaustible.

A French Scientific Expedition

In its column of Miscellanea for May 26, 1838, t *Athenæum* said: "We have frequently had to repo the progress of the Bonite during her voyage rou the world in order to take out the consular agen of France to different colonies. The following is brief summary of the scientific labours of the office on board. The voyage was completed in 631 da during which the corvette only anchored 151 day it has therefore been a matter of surprise that much should have been done for zoology, for amo a considerable collection of rarities five have be added, which form types of new genera, and of whic there was either no vestige in museums or only i perfect specimens; and beside these there are ma new species. . . . The phosphorescence of the has been an object of continual research and organised beings which cause it have been carefully preserved in spirits of wine. . . . With respect to Physics, observations with barometer, thermometer and other instruments have been made at every hour of the day and night. Some experiments made with the apparatus of M. Biot to ascertain the composition of sea water at a great depth have produced some unexpected results ; and among other things Terrestrial Magnetism has been carefully studied. M. Gaudichaua has been equally indefatigable with respect to Botany, and has brought home an immense collection of woods, plants, fruits, seeds, drawings and notes. . . ."

University Events

Aberdeen.—The A. W. Garden fellowships will be awarded in June by the Senate of Aberdeen University. They are tenable from 3–5 years, and are of an annual value not less than £200. Graduates of medicine of any British university are eligible, but preference will be given to Aberdeen graduates. Application should be made to the secretary of the University, Marischal College, Aberdeen, before May 31.

Cambridge.—B. Cooper, of Clare College, has been appointed University demonstrator in engineering.

An election to the Isaac Newton studentships will be held early in the Michaelmas Term 1938. These studentships are for the furtherance of advanced study and research in astronomy (especially gravitational astronomy, but also including the other branches of astronomy and astronomical physics) and physical optics. Those members of the University are eligible for the studentship who have obtained a degree in the University, and who were under the age of twenty-five years on the first day of January 1938.

At St. John's College, the following have been elected to fellowships : Dr. D. H. Valentine, University demonstrator in botany ; G. C. Evans.

Oxford.—M. A. Jennings, Lady Margaret Hall, has been elected to the Schorstein research fellowship in medicine.

A. C. Hardy, of Exeter College, professor of zoology and oceanography in University College, Hull, has been granted the degree of D.Sc. for his work on plankton.

Perth, W.A.—On March 31 the University of Western Australia, Perth, reached the semi-jubilee of its teaching work, and the occasion was celebrated by a conversazione in the Winthrop Hall of the University held on April 29.

Prof. H. E. Whitfeld, vice-chancellor of the University, has been granted extended leave to visit Europe, America and South Africa. During his absence, Prof. A. D. Ross, of the chair of physics, will be acting vice-chancellor.

Sheffield.—Dr. R. P. Linstead, lecturer in chemistry in the Imperial College, has been appointed to the chair of chemistry, in succession to Prof. G. M. Bennett, who has resigned.

Societies and Academies

London

Royal Society (*Proc.*, A, 165, 453–595, April 27, 1938).

W. R. G. Atkins : Photo-electric measurements of the seasonal variations in daylight around 0·41μ, from 1930 to 1937.

J. S. Foster, G. O. Langstroth and D. R. McRae : Quantitative spectrographic analysis of biological material. (3). A method for the determination of sodium and potassium in glandular secretions.

C. T. Archer : Thermal conduction in hydrogen-deuterium mixtures.

D. S. Kothari : The theory of pressure-ionization and its applications.

A. Fage : The influence of wall oscillations, wall rotation, and entry eddies, on the breakdown of laminar flow in an annular pipe.

N. Feather and E. Bretscher : Uranium Z and the problem of nuclear isomerism.

D. H. Bangham and S. Mosallam : The adsorption of vapours at plane surfaces of mica. (1).

C. F. Elam : The influence of rate of deformation on the tensile test with special reference to the yield point in iron and steel.

Proc., A., 166, 1–177, May 4, 1938.

M. Blackman : On the diamagnetic susceptibility of bismuth.

F. W. Jones : The measurement of particle size by the X-ray method.

A. D. Misener : The resistance of superconducting cylinders in a transverse magnetic field.

B. F. J. Schonland, D. B. Hodges and H Collens : Progressive lightning. (5). A comparison of photographic and electrical studies of the discharge process.

H. J. Woods : X-ray studies of the structure of hair, wool, and related fibres. (4). The molecular structure and elastic properties of the biological cells.

T. E. Allibone and J. M. Meek : The development of the spark discharge.

N. Kemmer : Quantum theory of Einstein-Bose particles and nuclear interaction.

H. Fröhlich, W. Heitler and N. Kemmer : On the nuclear forces and the magnetic moments of the neutron and the proton.

Paris

Academy of Sciences, March 21 (*C.R.*, 206, 865–960).

Marcel Delépine : A special action of catalytic nickel during the hydrogenation of 2-methyl-4-amino-5-cyanopyrimidine.

Jean Cabannes, Jean Dufay and Junior Gauzit : Presence of sodium in the upper atmosphere. From observations on the yellow radiation of the nocturnal sky, made by interference methods, it is concluded that the vapour of sodium is a permanent constituent of the atmosphere.

Lucien Daniel : An unquestionable case of the heredity of acquired characters. Results of experiments on the grafting of the artichoke on the annual sunflower, tubercles appearing on the roots of the latter. In the fifth generation raised from seed, the variety *Helianthus tuberosus Costantini* has been found and this has inherited various characters of the grafted ancestor, including the tubercular roots. This variety, cultivated through the tubers, preserves the production of tubers on its roots.

Marc Krasner: The number of primitive superbodies of a given degree and the number of metagaloisian superbodies of a given degree of a body of g-adic numbers.

Léonidas Kantorovitch: The continuity and prolongation of linear operations.

Assène Datzeff: The graphical integration of certain differential equations.

V. A. Kostitzin: The Mendelian coefficients of heredity.

Mme. Christiane Pauc: The geometrical interpretation in non-holonome varieties of the theories of integration of systems of Pfaff equations.

Frédéric Roger: The equivalence of the ideas of quadrature and of primitive.

Jean Villey: Carburation by transference.

Roger Kling and Numa Manson: Liquid jets impelled with supersonic velocities.

Robert Fleurent and Maurice Beauvilain: The measurement of the time of reflection and acoustic levels by means of the fluxmeter.

Pierre Biquard: Study of the propagation of ultra-sounds in liquids under pressure. Description of experiments on benzene, toluene, methyl acetate and carbon tetrachloride at pressures ranging up to 700 kgm. per sq. cm.

Serge Gorodetzky: Analysis of the working of a selector with multiple coincidences. Description of an experimental arrangement.

Mlle. Marguerite Quintin: The potential of cadmium in cadmium benzenesulphonate.

Georges Ahier: Some dispersive liquids. Suggestions for various liquids capable of replacing ethyl cinnamate in prisms, possessing a lower temperature coefficient for the index of refraction and being less liable to change.

Raymond Ricard: The first spark spectrum of cæsium.

Mme. Irene Curie and Paul Savitch: The radio-element with a period of 3·5 hours formed in uranium irradiated with neutrons.

Mlle. Marcelle Pernot: The system mercuric iodide, cæsium iodide and water.

Clément Courty: The calcination residues attracted by a magnet. The application of the Curie-Chéneveau magnetic balance to the determination of minimal quantities of iron.

Victor Auger: The molybdic acid, H_4MoO_5. This acid is the yellow deposit from nitromolybdic solutions, and always contains ammonia. Various alternative methods of preparation are compared.

André Boullé: The dehydration of acid sodium pyrophosphate.

Mme. Yvonne Khouvine and Georges Arragon: The acetylation of perseulose.

Martin Battegay and Robert Krebs: The thiocarbamic esters.

Max Mousseron and Robert Granger: The dealkylation by sulphuric acid of the monoethers of the 1,2-cyclanediols with C_5 and C_6.

P. Bellair: The tectonic arrangement of the Provençal accidents.

Em. de Martonne: The tropical model in Brazil.

René Bernard: The interferential study of the yellow radiation λ 5893 A. of the twilight sky and the proof of the presence of sodium in the upper atmosphere (see also Nature of April 30, p. 788).

Georges Déjardin: The possible presence of certain lines of the neutral atom of sodium in the spectrum of the night sky. The hypothesis of the cosmic origin of atmospheric sodium cannot be rejected *a priori*.

Georges Lemée: The ecological characters of the Europeo-Atlantic floral element in the north-west of France.

Constantin Dawydoff: The endolarval metamorphosis in some Phyllodocians of Indo-China.

Jean Henri Vivien: The existence of accessory glands in the genital tract in the male of *Gobius paganellus*.

Léon Acolat: The distribution of the arterial and venous blood in the central arteries of batrachians and reptiles.

Henri Bierry and Bernard Gouzon: The spectral detection of the œstrogenic hormones in the urine of a pregnant woman. The method described, based on fluorescence spectra, characterizes the œstrogenic hormones, without confusion with cholesterol or other interfering substances.

Mme. Vera Dantchakoff: The rôle of hormones in the manifestation of the sexual instincts.

Maurice Lemoigne, Pierre Monguillon and Robert Désveaux: The reduction of nitrous acid by cystein and glutathione. Cystein and glutathione, like ascorbic acid, reduce nitrous acid with formation of hydroxylamine and ammonia.

Emile Rousseau: Melanine fixed on the non-dialysable protein complexes of the blood and of the urine of cancerous patients.

A. Sartory, J. Meyer and J. Waeldelé: Contribution to the study of a violaceine obtained in the crystalline state and arising from a violet bacillus isolated from the pus of a dental abscess.

Constantin Levaditi, Jules Bridré and Mme. Denise Krassnoff: The approximate dimensions of the claveau virus determined by ultrafiltration.

Marcel Lisbonne, Georges Roman and Gérard Renoux: The vaccination of the guinea pig against the brucellic infection (*Brucella melitensis*).

Max Aron: Serological researches on the existence of specific properties of the urine and blood of tuberculous patients.

Ivan Bertrand and Raoul Lecoq: Anatomical alterations of the peripheral nerves in the course of acute disturbance of food equilibrium of glucidic origin.

Dublin

Royal Irish Academy, April 11.

J. C. Harper and J. J. Hartley: The Silurian Inlier of Lisbellaw, Co. Fermanagh, with a note on the age of the Fintona Beds. This inlier, bounded by faults, was, in the Survey map of 1881, shown as consisting of both Llandeilo and upper Llandovery deposits. The whole is now shown to belong to the *Monograptus gregarius* zone of the Middle Valentian. It is one of the most north-westerly exposures of the Silurian System in the British Isles. A coarse conglomerate occurs having a sharp junction with the prevailing mudstones. *Pteraspis* is reported from the adjacent Fintona Beds, thus fixing their age as Lower O.R.S.

Cape Town

Royal Society of South Africa, March 16

Pottery from the Salisbury District, Southern Rhodesia. (1) Rev. Fr. Stapleton: The topography of Echo Farm, Didcot Farm, and the ruins on Didcot

Farm. (2) J. F. Schofield: The pottery from Echo Farm, Didcot Farm, and the ruins on Didcot Farm. (3) J. F. Schofield: A proposed classification for the pottery of Southern Rhodesia. (4) J. F. Schofield: Notes on iron implements from Echo Farm.

Geneva

Society of Physics and Natural History, March 3.

Renée Dovaz: The action of pre-pituitary extracts on the development of the organ of Bidder in the male castrated toad. Injections of prolan from the urine of ovariectomized woman, insertions and injections of hypophyses of frogs and toads into male castrated toads stimulate the transformation of Bidder's organ into the ovary, without, however, resulting in development as rapid as that described by Houssay, whose views were based on the weight of the organ. The effect on the ovocytes is in direct relation with the period of latency after castration. In the most favourable cases, a commencement of vitellogenesis is noticed in the ovocytes. The transformation observed is of the same order of magnitude as that undergone by the ovaries themselves, as will be described in a later note.

Renée Dovaz: The stimulation of sexual maturity in immature male and female toads, under the influence of pre-pituitary extracts. The injection into toads (*Bufo vulgaris*) of pituitary extracts (ox, toad, frog) and of prolan from the urine of ovariectomized woman, slightly stimulates the ovogenesis of immature females, and, more actively, the ovogenesis of the Bidder's organs of castrated males, still more actively, the spermatogenesis of immature males or, in a state of sexual prematurity, Bidder's organ behaves abnormally, and is activated at the same time as the ovary and testicle. The study of the problem would require that attention should be given to the time factor, on account of the slow development of the batrachians.

Ludwig Blum: The polarity of the buffer action in the tissues of an aquatic plant (*Potamogeton densus*). The buffer power of an aquatic plant (*P. densus*) has been measured towards acids and bases. The measurements were carried out on the apical and on the distal part of the stems. The *p*H of the stems is always distinctly acid and the buffering power against acids is more important than against bases. In general, the apical part shows a higher buffering power than the distal part.

Willy J. Schroeder: The discovery of submarine coulées of lava in the Flysch of the sheet of la Brèche. The author has identified in the crest situated between "Sur le Verchaix" and the pass of Jouxplane to the north of Samoëns (Haute-Savoie) submarine coulées of lava interstratified in the lower levels of the Flysch of the la Brèche sheet. Certain parts of the coulée are massive, others have a typical pillow-lava structure.

Willy J. Schroeder: Remarks concerning the coulées of lava in the Flysch in the la Brèche sheet. The most probable hypothesis concerning the origin of these coulées would be the following: A good part of the basic eruptive rocks of the Flysch of the la Brèche sheet would be remnants of submarine coulées of lava which date from the period of the deposit of the Flysch. The la Brèche sheet would then come from the eastern part of the zone of the Flysch and the crystalline rocks forming the lava would come from the zone of the green rocks of Versoyen.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, May 23

Wellcome Institute for Medical Research, at 5.30.—Dr. J. W. Trevan: "Variation in the Response of Animals to Drugs" (succeeding lectures on May 24 and 25).*

University of Oxford.—Prof. J. H. Hutton: "A Primitive Philosophy of Life" (Frazer Lecture).

Tuesday, May 24

Royal College of Physicians, at 5.—Prof. F. R. Fraser: "The Clinical Aspects of the Transmission of the Effects of Nervous Impulses by Acetyl Choline". (Croonian Lectures. Succeeding lectures on May 26 and 31).

Eugenics Society (at the Royal Society, Burlington House, W.1), at 5.15.—D. V. Glass: "Population Policies in Scandinavia and Elsewhere".*

Birkbeck College, London, at 6.—Prof. J. B. S. Haldane, F.R.S.: "The Marxist Philosophy" (Haldane Memorial Lecture).*

Institution of Mechanical Engineers, at 8.—Prof. H. J. Collins: "Engineering Problems of Modern Building Construction" (Chadwick Public Lecture).*

Wednesday, May 25

National Institute of Industrial Psychology (at the London School of Hygiene and Tropical Medicine), at 5.30.—Dr. Dwight L. Palmer: "Industrial Relations in the United States and Great Britain" (succeeding lectures on May 30, by Dr. C. H. Northcott, and on June 1, by Prof. John Hilton).*

Thursday, May 26

Royal Society, at 2.30.—Discussion on "Cosmic Rays" to be opened by Prof. P. M. S. Blackett, F.R.S.

Friday, May 27

Geophysical Discussion (at the Royal Astronomical Society), at 4.30.—"The Topography of the Ocean Floor" (Opener: Lieut.-Colonel R. B. S. Sewell, F.R.S.).

Royal Institution, at 9.—Prof. J. Chadwick, F.R.S.: "The Cyclotron and its Applications".

Rubber Technology Conference, May 23–25. To be held at the Hotel Victoria, Northumberland Avenue, London, W.C.2.

S. T. Rowe: President.

Linnean Society of London, May 24–26. One hundred and fiftieth anniversary to be held in London.

May 24, at 3.—Dr. J. Ramsbottom: "Linnæus and the Species Concept".

May 25, at 10.—Symposium on "The Concept of Species from the Time of Linnæus to the Present Day".

May 26, at 10.—Symposium on "Geographical Isolation as a Factor in Species Formation".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned.

Lecturers in Mathematics, Physics, Chemistry and Civil and Mechanical Engineering in the Woolwich Polytechnic, London, S.E.18—The Secretary (May 21).

Lecturer in Telecommunications (June 3) and **Lecturer in Mechanical Engineering** (May 23) in the Polytechnic, Regent Street, London, W.1—The Principal.

Head of the Department of Economics and Social Studies in the City of Birmingham Commercial College, Suffolk Street, Birmingham, 1—The Principal (May 25).

DEMONSTRATOR IN ELECTRICAL ENGINEERING in the Military College of Science, Woolwich, S.E.18—The Commandant (May 26)

LECTURER IN MECHANICAL ENGINEERING in King's College, London —The Secretary (May 27).

CHEMISTS under the War Department Chemist—The Under-Secretary of State (C.5), The War Office, S.W 1 (May 28).

TEACHERS OF CHEMISTRY AND OF MECHANICAL ENGINEERING in the Luton Technical College—The Director of Education, Shire Hall, Bedford (May 28).

HEAD OF THE DEPARTMENT OF PHYSICS in the Chelsea Polytechnic, London, S.W.3—The Principal (May 28).

LECTURERS IN MATHEMATICS, CHEMISTRY AND ENGINEERING in the Derby Technical School—The Clerk to the Governors, Derby Technical School, Normanton Road, Derby (May 28).

LECTURER IN MECHANICAL ENGINEERING in the St. Helen's Municipal Technical School—The Director of Education, Education Office, St. Helens (May 28).

TEACHER OF ENGINEERING DRAWING, MATHEMATICS AND SCIENCE in the Rochdale Municipal Technical School—The Secretary (May 30).

ASSISTANT (Grade III) for abstracting scientific and industrial papers at the D.S I R, 16 Old Queen Street, Westminster, S.W.1—The Establishment Officer (May 30).

TEXTILE ENGINEER to the Wool Industries Research Association, Torridon, Leeds—The Secretary (May 31)

UNIVERSITY DEMONSTRATOR IN CHEMISTRY in the University of Cambridge—Prof R G W Norrish, University Chemical Laboratory, Pembroke Street, Cambridge (May 31)

TEACHER OF PHYSICS in the Rugby College of Technology and Arts —P. I. Kitchen, 61 Clifton Road. Rugby (May 31).

BACTERIOLOGIST in the Veterinary Department, Kenya—The Director of Recruitment (Colonial Service), 8 Buckingham Gate, London, S W 1 (May 31).

LECTURER IN ELECTRICAL ENGINEERING in the Carlisle Technical School—The Director of Education, Education Offices, Fisher Street, Carlisle (June 1).

ASSISTANT LECTURER IN CHEMISTRY in the University of Manchester —The Registrar (June 2).

LECTURER IN MATHEMATICS in University College, Dundee—The Secretary, University, St. Andrews (June 4).

TWO UNIVERSITY LECTURERS IN ZOOLOGY and ONE UNIVERSITY DEMONSTRATOR IN BOTANY in the University of Cambridge—Dr. A. D Imms, Department of Zoology, Downing Street, Cambridge (June 7)

TWO CHEMISTS AND TWO FIELD GEOLOGISTS in the Geological Survey Department of the Federated Malay States—Director of Recruitment (Colonial Service), 8 Buckingham Gate, Westminster, London, S W 1 (June 10)

PROFESSOR OF BIOCHEMISTRY in the All-India Institute of Hygiene and Public Health, Calcutta—High Commissioner for India, General Department, India House, Aldwych, W.C.2 (June 24).

LECTURER IN CHEMISTRY in the University of Reading—The Registrar.

JUNIOR INVESTIGATOR to the British Non-Ferrous Metals Research Association—The Secretary, B.N.F.M R A, 1–6 Regnart Buildings, Euston Street, N W.1.

Scientific Research in International Affairs

"IN the revolution of thought through which we are living, the profoundest and most disturbing element is the breakdown of that ethical system which, since the days of Constantine, has imposed upon European culture at least the semblance of moral unity." This remark made by the regius professor of Greek at Oxford in his inaugural lecture last year, was recalled by Sir Alfred Zimmern in his address at Chatham House last October on the decline of international standards. Recent events should convince the dullest mind of the extent to which international standards have deteriorated and the anarchy which threatens the repudiation of law and order in favour of brute force.

Sir Alfred Zimmern suggests that among the factors which have led to the deterioration of international standards the weakening of the Christian ethics and sanctions is significant; and there will be those ready to place upon science some of the responsibility for weakening such sanction and belief. However profound may have been the influence of science upon religious thought, the whole trend of scientific thought is in the direction of law and order, and in recent years there has been mutual recognition of the spiritual purposes of both science and religion if mankind is to regain control over events.

The present crisis places beyond question the supreme importance of some alliance of moral and scientific forces if the downfall of civilization is to be averted; and scientific workers in those centres where science still retains its freedom of thought and speech will be as united in their repudiation of the methods by which these are being repressed as they will be sincere in their sympathy for those distinguished men of science whose work and freedom are now threatened.

Outside the totalitarian States, differing political views are indeed largely determined not so much by matters of fact—though, of course, the extent to which particular holders of them have access to the facts may well vary enormously—but also, and even more important, by questions of judgment and values. It is precisely this point which was emphasized by Prof. M. Ginsberg in his thoughtful paper to the British Association at Nottingham last year. The present situation does indeed throw down yet a further challenge to the universities to play their part more fully in shaping and moulding a public opinion competent to sort out the issues and form sound judgments on questions of value as well as of fact.

In this respect, as Prof. Ginsberg has shown, the contribution of science is largely one of technique to resolve the difficulties in the way of clear, accurate and unprejudiced thought. This is, however, far from being the only contribution of science to the problem of international relations at the present time. Fully as significant is the question of painstaking and accurate research into the basic facts upon and by which decisions must be based, judgment determined and policy guided. Of the contribution which science could make in this field there could be no more admirable illustration than is offered by the study of the work of the Institute of Pacific Relations and its bearing on the problem of peaceful change, by H. F. Angus, which was issued for the Tenth International Studies Conference at Paris last June.

In this particular study, Mr. Angus is not concerned with practical issues, but he gives an impressive picture of the wide field for research which such questions as trade and tariffs, comparative standards of living, land utilization, population and migration, commercialization or industrialization present in China and in other Pacific countries. The basic research involved in the solution of such problems has its bearing on such particular questions as the Chinese claims for the rendition of Shanghai and other settlements and concessions, for tariff autonomy and the abolition of extra territoriality, and no one can read this study without realizing how imperfect as yet are the knowledge and facts available for the decision of many of the problems the solution of which is being attempted so unhappily by force at the present moment.

It is true, of course, that research in itself can accomplish very little in promoting the peaceful settlement of disputes, and the significance of the Institute of Pacific Relations lies in the use made of its research. By referring the conflict of beliefs to the arbitrament of research, it is possible to banish the acrimony which often embitters international relations through the conflict of different beliefs held by parties to the dispute. A politician may find it necessary, in order to retain his popularity, to reiterate the beliefs generally held by his supporters. It is a different matter for him, however, to repeat the same views in quarters in which repetition will appear merely as evidence of his ignorance or his insincerity.

Part of the achievement of the Institute of Pacific Relations has been to bring international controversy into the atmosphere of scientific research, but as yet it has made no determined effort to diffuse this atmosphere among the general public by making accurate information and its thoughtful interpretation widely available. There has, of course, been a great improvement in the position here in recent years. The extent to which careful analysis has been made in the scientific spirit of the facts which lie behind the demands of a nation for an alteration of the *status quo* is being made plain by the publications of the Institute of Pacific Relations, the Royal Institute of International Affairs and other such organizations. Though the field of research is still immense, much is being done and is already available as a basis for action if Governments and nations are prepared to use the results of such research.

It is here that we reach the crucial issue at the present. The degree to which force is being accepted as the means for one-sided redress of real or imagined grievances raises new and disturbing issues, and it becomes more and more difficult to deal justly even with the original matters in dispute. The indignation raised by Japan's campaign in China, for example, leads many to overlook the genuineness of many of her grievances and the sincerity of her point of view. Sir Alfred Zimmern's address indicates how grave has been the deterioration in this field and how imperative is the work of education and of promoting a social integration between countries and groups of centres which will give the existing organization for co-operation an opportunity to function.

It is still true that public opinion remains the decisive factor in determining the conduct of foreign affairs and international relations by any Government. The Press and broadcasting and educational policy are, under modern conditions, far more potent instruments than ever before by which a Government can influence public opinion. But none the less, even in the totalitarian State, a Government can rarely proceed far in advance of the point for which propaganda has prepared its supporters, and may easily on the other hand arouse feelings which carry it far beyond the point at which it intended to halt.

It is this situation, in which nationals of one country make little or no attempt to appreciate the point of view of those of another, and do not seek to understand the reasons for one another's prejudices, that constitutes one of the greatest obstacles to international progress and co-operation to-day. International agreements, whether between individual powers or collectively through the League of Nations, have little force unless there is some common standard and measure of understanding in the minds of the parties to them. To promote such understanding and standards is of vital importance. The real significance of the admirable non-political work of the League of Nations to-day in the field of health, the settlement of refugees, the protection of women and children, the suppression of slavery and the control of the trade in opium and other narcotic drugs, or its reconstruction work like that in Austria, Hungary, Greece or in China, now interrupted by the war, like the work of the International Labour Organization, lies not less in the direct contribution offered to the relief of human suffering and distress than in the extent to which it prepares the way for understanding and good will and co-operation in a wider field.

The history of international sanctions, as revealed in the important recent study by a group of members of the Royal Institute of International Affairs, does not indeed indicate the invalidity of sanctions. What it reveals is the dangerous loose-thinking in this subject, the widely differing standards of values and thought in different centres. It demonstrates beyond question that collective security can only function effectively when public opinion in the different countries has been educated out of its parochialism and brought to an appreciation of what is really involved in international relations in this new world, in which the forces that science has placed at our disposal have much power to build or to destroy.

Those responsible for this wise and well-balanced study were not concerned directly with the larger questions as to whether or no the attempt to establish a world order on the basis of international law should be continued. Their purpose was rather to discover how far the constitution of a system of sanctions for the enforcement of international legal obligations is a feasible proposition. To this question they give no categorical answer. The book embodying the results of their investigation marshals the facts and analyses the experience so that others may be in a position to form their own conclusions. None the less, if the weaknesses and dangers of sanctions as hitherto applied are clearly expressed, the report puts the pregnant question whether, if the world lacks the spirit of courageous and self-sacrificing co-operation on which sanctions depend, any alternative course is available whereby the calamity of war can be permanently averted. The whole trend of recent events reinforces these pleas for calm and courageous thinking, and for a moral basis for the wise and determined action which must be taken if the rich heritage of civilization as we know it to-day is to be preserved from relapse into barbarism.

The Fourth Estate

Report on the British Press: a Survey of its Current Operations and Problems, with special reference to National Newspapers and their Part in Public Affairs. Pp. ix + 333. (London: Political and Economic Planning, 1938.) 10*s.* 6*d.*

THERE could be no more appropriate time than the present for a searching examination and re-appraisal of the British Press. Over a large part of the globe, freedom of thought and of speech has disappeared; and in the countries where truth still survives, its free expression is being subjected to economic, political and social pressures never before known except in time of war. The continued freedom of the Press, once taken for granted, is by no means a certainty even in Great Britain, if the intolerable political stresses of the past two or three years are not eased soon.

Moreover, there are many in Great Britain, devoted to the cause of truth, who cannot regard the present-day freedom of the Press as an unmixed blessing. Dissatisfaction with the performance of the British Press is growing, almost as fast in Fleet Street as elsewhere. How satisfactorily does the Press inform its readers promptly, truthfully, fairly, of what is going on in the world? How seriously is it dominated by its commercial proprietors or by outside pressure-groups like the advertisers? Is it, in fact, living up to its high position as the Fourth Estate?

These are only a few of the scores of pertinent questions which the research workers of P E P (Political and Economic Planning) have sought to answer in their admirable report on the British Press, published after three years of effort. The report makes no claim to be exhaustive; indeed, its authors found the utmost difficulty in assembling the material needed for what they have modestly described as a "preliminary analysis". Too often they have had to use one newspaper office as the source of their detailed information, although they should have had the co-operation of all.

Within its admitted limitations, their work is, however, beyond praise as a severely objective study of what is at the same time a great industry, a vital profession and a public utility of incalculable importance. The report is a rich storehouse of information on every conceivable aspect of British newspapers. It tells, in astonishing detail, how newspapers are produced, how they are financed, how the news is gathered. It takes the layman behind the scenes in newspaper offices on a night when some important event "breaks" after the first edition has gone to press. Considering the speed and pressure of daily newspaper production, it is one of the miracles of modern life that they should be as complete and as accurate as they are.

Yet this report is by no means a 'white-washing' document. It at least touches upon most of the shortcomings of the British Press and finds much cause for uneasiness. Admitting that all the British newspapers cannot and should not be remade in the image of *The Times* or the *Yorkshire Post* or the *Manchester Guardian*, the report finds particular fault with the reporting of scientific news. It doubts whether the Press "is adapting itself quickly enough to the growing output of potential scientific and industrial news and the growing demand for it". Scientific workers would do well to browse through these sections of the report; for the gulf between Fleet Street and the science laboratories is wider, perhaps, than between the public and any other field of endeavour.

> "Frequently," says the report, "good stories from the laboratory and the studio are bungled and misrepresented, simply because the journalist who writes them up cannot grasp their real significance. The ability to reason scientifically, the scientist's respect for facts, is essentially the product of higher education, and it is precisely this that so many journalists have missed. . . . Really competent scientific journalists, who are both good scientists and good journalists, are few and far between, and regarded as neither fish, flesh nor good red herring by scientists and journalists alike."

In short, the British Press, with one or two exceptions, does not yet know or care to know how to report scientific news. "The public doesn't want it" is the defence of nine editors out of ten—most of them unaware of the interest in scientific news which has been built up by intelligent reporting and editing, and by the co-operation of men of science, in the United States and Canada. In Great Britain scientists (again with a few exceptions) are apt to be distrustful of the Press and have as little to do with it as possible.

The fault, as the report sees it, is fairly evenly divided, and will require conscious effort by newspapers and scientists to correct it. On the newspapers' side the chief fault appears to be the slipshod recruitment of journalists. The habit of most Fleet Street organizations is to recruit their reporters from half-educated young men who have served apprenticeships on provincial newspapers from the age of fifteen or sixteen. The editors' prejudice is to distrust specialists and to assign everyday reporters, without the slightest training in science, to 'cover' such events as the meetings of the British Association. The result is the imbecilic 'bright' reporting one encounters all too often at the time of a British Association meeting, with trivial remarks picked out of Section E or Section L to make a good headline, while announcements of outstanding importance in fields of nuclear physics or genetics or medical research are left unreported.

The remedy, therefore, lies partly in the news editors' hands. If an editor makes up his mind that the public will read scientific news, and if he assigns his best qualified reporter to find it and write it, we may yet have adequate science news in the British Press. But men of science themselves also have it in their power to correct many of the evils of which this report complains. The late Lord Rutherford was not too busy, or too eminent, to help any reasonably intelligent journalist who came to him in search of 'background' information for science news. The achievements of the Cavendish Laboratory became known throughout the world because Lord Rutherford, without self-seeking or self-advertisement, liked the world to know what he and his colleagues were doing. It requires much patience for a scientific investigator to describe an experiment to non-technical journalist in non-technical language. It calls, also, for a broad outlook which is not always found in science laboratories. But, as this report indicates, the improvement of scientific news in Great Britain is a job worth doing. For there can be no public awareness of the mighty influence and inspiration of the scientific spirit unless science makes itself known.

Sex and Society

Sex in Relation to Society

Being the first English edition of Vol. 6 of "Studies in the Psychology of Sex", abridged and revised. By Havelock Ellis. Pp. xv + 529. (London: William Heinemann (Medical Books), Ltd., 1937.) 12*s*. 6*d*. net.

HAVELOCK ELLIS'S book is a new edition, abridged and revised throughout, of the concluding volume of his monumental "Studies in the Psychology of Sex", the greatest contribution to the subject ever made by any single writer. The original edition, however, is not thereby superseded, the present one being intended for a wider public. The author points out that thirty years ago his work on the problems of sex had to be published in a way that made it accessible only to specialists, whereas since then social and legal opinion has so far changed that it can now be presented to all serious readers. This is an important fact. For in the field of the marriage institution, only a very strong public opinion is able to effect reforms in the face of ancient entrenched traditions. Havelock Ellis says that this is particularly the case in England.

Among the reforms there is none that he has insisted on more strenuously than a change of the English divorce law. The most serious and the most profoundly unnatural feature of the ecclesiastical conception of marriage was "the flagrant contradiction between the extreme facility with which the gate of marriage was flung open to the young couple, even if they were little more than children, and the extreme rigour with which it was locked and bolted when they were inside. That is still the defect of the marriage system we have inherited from the Church". What is particularly needed is, that if a husband and wife can no longer live together, they should be allowed to part amicably, and in harmonious agreement effect all the arrangements rendered necessary by their separation; but "the law ridiculously forbids them to do so, and declares that they must not part at all unless they are willing to part as enemies".

Strangely enough, many legislators are still imbued with the idea that a marriage must inevitably end in a catastrophe, either by the death or some great misfortune of one of the consorts or by the commission of a criminal or immoral act, which is evidently regarded as a more proper ground or excuse for dissolving the marriage than the mutual agreement of both. Yet divorce by mutual consent is very ancient in European legislation. According to Roman law, a 'free' marriage could be dissolved either by mutual agreement between both parties or by the will of one party only, and divorce by mutual consent was permitted in the Roman Empire even in Christian times. The facility of such divorce remained in the Roman codes of the German kings; and those subjects of the Western rulers who elected to live under the old Teutonic systems of law seem to have had an equal facility, as is suggested by the dooms of Aethelbirht, Christian though they be. In modern times, divorce by mutual consent was reintroduced in France by the law of divorce of 1792—not, as has been alleged, by Napoleon, who on the contrary made such divorce more difficult, after that law had been in existence during twelve years. Nowadays a marriage may be dissolved upon the common application of the parties, after a short period of separation, in a few Catholic countries and in the States of northern Europe.

The present book contains twelve chapters, dealing with such subjects as sexual education, the function of chastity, the problem of sexual abstinence, prostitution, sexual morality, marriage, the art of love, the science of procreation. Each of these chapters is full of interesting and instructive facts, presented with none of the aridity so often found in scientific works, and accompanied by illuminating and well-balanced judgments, most of which every unprejudiced reader is bound to accept. In discussions of this kind, however, there is always likely to be some difference of opinion; which gives even the most appreciative reviewer an opportunity to express certain views of his own.

To the reviewer, it seems that Havelock Ellis's high estimation of sexual love—which he defines as a synthesis of lust and friendship—has made him unduly severe upon marriages contracted from other motives. He writes: "A man who marries for money or for ambition is departing from the biological moral ends of marriage. A woman who sells herself for life is morally on the same level as one who sells herself for a night." It would seem that wealth is better fitted than poverty for the biological purposes of procreation and the rearing of children, and, as Marañon remarks, a man's money is among ourselves a quasi-biological substitute for his physical ability in early times as a means of supporting his family. Further, how do the severe strictures upon mercenary marriages square with the statement that the community has no right to interest itself in the sexual behaviour of its members until a child is born or conceived, and that "it is an impertinence, if not an outrage, to seek to inquire into it?" Economic considerations are certainly of great importance at the conclusion of a marriage. Poverty may cause much hardship to the couple, and may prevent them from having children, or, if they have any, from giving them a proper education; and even some amount of wealth is not to be despised. No wonder, therefore, that economic circumstances influence very largely the choice of a partner.

Indeed, it is a very common observation that love-matches, especially early ones, easily come to grief. Schopenhauer quotes in support of his own opinion the Spanish proverb, "Quien se casa por amores, ha de vivir con dolores" ("He who marries for love has to live in sorrow"). Lord Beaconsfield wrote in his younger days: "All my friends who have married for love and beauty either beat their wives or live apart from them. This is literally the case." Bloch says "it is a well-known fact that marriages of reason are often more enduring than love-marriages". Loewenfeld points to cases of so-called "marriages of convenience" which in the course of years took on a form that converted connubial fellowship into a source of purest conjugal happiness for both parties concerned. Though love is commonly considered to be the proper motive for a marriage, it is, after all, more important that the parties should love each other after marriage than before.

In another respect, Havelock Ellis rather seems to be too tolerant. He opposes the view that marriage is a contract in the true sense, but admits that the entrance into the world of a child should be preceded by the formation of "a marriage contract which, while in no way binding the father and mother to any duties, or any privileges, towards each other", binds them towards their child—"a contract which leaves entirely unaffected their past, present, or future relations towards other persons". How is that possible ? The presence of the child certainly imposes duties on the father and mother in their behaviour towards each other, which in a very high degree affect the welfare of the child. Havelock Ellis seems to regard jealousy as a useless and stupid feeling, which, as he says, seldom makes a person more lovable, and frequently much less lovable. But if a married person behaves in a manner that causes jealousy in the other partner, the relations between them may be seriously disturbed thereby ; and, as Mr. Shaw says, "an unhappy household is a bad nursery".

EDWARD WESTERMARCK.

Petrology and Mineralogy

(1) **The Petrology of the Igneous Rocks**
By the late Dr. F. H. Hatch and Dr. A. K. Wells. (Text-Book of Petrology, Vol. 1). Ninth edition. Pp. xx + 368. (London : George Allen and Unwin, Ltd., 1937). 15*s*. net.

(2) **Elements of Optical Mineralogy :**
an Introduction to Microscopic Petrography. By Prof. Alexander N. Winchell. Fifth edition, revised and enlarged. Part 1 : Principles and Methods. Pp. xii + 263. (New York : John Wiley and Sons, Inc. ; London : Chapman and Hall, Ltd., 1937). 17*s*. 6*d*. net.

(3) **Introduction to the Study of Minerals**
By Prof. Austin Flint Rogers ; with a Section on Microchemical Analysis, by Dr. Lloyd W. Staples. Third edition. Pp. xviii + 626. (New York and London : McGraw-Hill Book Co. Inc., 1937). 30*s*.

(1) THE appearance of a revised edition of Hatch and Wells's "Petrology of the Igneous Rocks" is a matter of interest to British petrologists, since this has long been a standard text-book in British universities. Owing to the death of Dr. Hatch, the work is now, so far as the introduction of new matter is concerned, that of Dr. Wells, and this author has incorporated in the new edition, not only new material but also new ideas.

A most important innovation is the introduction of a new scheme of classification which, the author states, he has advocated and taught for years. Actually the scheme is, in principle, that recommended by a committee of the British Association in a preliminary report issued in the *Geological Magazine* in July 1936. This report was published with the view of attracting criticism and suggestions for the improvement of the proposed scheme, with the realization that it could only prove successful in so far as it met with general approval.

The essentials of the new classification are : (1) that the name given to a rock shall no longer carry any implication of *mode of occurrence* (for example ; plutonic, hypabyssal, or extrusive) ; (2) that the names now proposed for the main rock types are based on, and imply a definite *grain size* for the ground-mass (ignoring phenocrysts). Only a brief outline of the new plan can be given here. Dr. Wells first divides rocks into 'clans' on a chemico-mineralogical basis. Each clan is then sub-divided into three major classes, defined in terms of grain size. One example will suffice as an illustration. The granite clan is subdivided into granites, coarse-grained rocks of grain diameter exceeding 0·5 mm., micro-granites with grain diameter 0·5–0·05 mm., and rhyolites with crystals of grain diameter of less than 0·05 mm and not exceeding 0·0025 sq. mm. in area. Mode of occurrence can still, of course, be indicated by prefixing a suitable adjective to the rock name

The committee's report dealt only with the granite and gabbro series, and it is, apparently Dr. Wells alone who has assumed the responsibility of publishing a complete new classification, before the committee has issued a final report. This may be one way of testing geological opinion, but it is questionable whether it is advisable to adopt in a widely used text-book, a system not ye generally accepted. In any event it is unfortunate that the definitions of the new classification are not set out clearly, preferably in tabular form at the beginning of each section. It would also have been an advantage for students to have indicated which are the new rock names no previously in general use.

The classification has the advantage that i simplifies the teaching of petrology, and, to some extent, if it were generally accepted, it migh ultimately simplify the literature of petrology

Judging by the fate of other attempts at reform, this seems unlikely. Dr. Wells himself, for example, still uses terms, the disuse of which was recommended by a strong committee on nomenclature so long ago as 1921.

The chapter on the metamorphism of the igneous rocks has been omitted.

So much for the changes in the book, the desirability of which is a matter of opinion. There are also certain points that call for criticism. In Part 5, on cycles of igneous activity, the section on North Wales has been considerably enlarged. This is all to the good, but in dealing with the equally interesting igneous rocks of Scotland and the Border the treatment is unequal, and Dr. Wells has not always made full use of new work. The dyke swarms surrounding the Cheviot granite are no longer regarded as radial, and a more up-to-date diagram is available. This information can scarcely have escaped the author's notice, since he actually refers to the memoir in which it appears. There is no mention of the extensive Strontian granite mass, which was carefully described a few years ago. The Permian lavas of Ayrshire are erroneously shown in two text-figures as Carboniferous. Other lavas of the same age in Dumfriesshire are not mentioned. There are one or two other defects of a like nature, of which space forbids mention.

Hatch and Wells's text-book, being so well known, attracts criticism that a less widely used book might have been spared. It only remains to state that in a new and more attractive format it still retains its character as an excellent and readable introduction to the petrology of the igneous rocks.

(2) No important changes have been made in the fifth edition of Part 1 of Winchell's well-known text-book, but a number of corrections and additions have been incorporated. Among the latter may be mentioned the inclusion of illustrations of the latest models of polarizing microscopes.

(3) The scope of Rogers's "Introduction to the Study of Minerals" has been enlarged in the third edition by the inclusion of a section on microchemical analysis. The whole work has been thoroughly revised, particularly the sections on crystallography; and the determinative tables have been enlarged by the inclusion of forty-seven additional species A novel and useful feature of the latter section is the listing of the French and German equivalents of mineral names.

Mortality in the United States

Twenty-Five Years of Health Progress:
A Study of the Mortality Experience among the Industrial Policyholders of the Metropolitan Life Insurance Company 1911 to 1935. By Dr. Louis I. Dublin and Dr. Alfred J. Lotka. Pp. xi+611. (New York: Metropolitan Life Insurance Company, 1937.)

THIS interesting volume records the experience of more than 340 million years of life, with nearly three million two hundred thousand deaths, observed in the twenty-five years 1911–35. The industrial policy holders consist mainly of urban populations at the lower level of income, so that their mortality rates would be expected to be somewhat higher than those of the whole population of the same age groups. That is, in fact, the case, but there is clear evidence of convergence, a gratifying testimony to the effects of modern sanitary progress. The trends of mortality rates for the very large number of separate causes of death examined are so similar to those of the United States where comparison is possible, that the volume may be taken as a reliable index of the changes of the last twenty-five years.

In the very large majority of instances, the secular movement in America has been similar to that in Great Britain; thus what is said in this volume of changes in mortality from tuberculosis, cancer, diabetes and cardiac diseases might be applied almost unmodified to English experience. The authors comment energetically on the black record of the United States with respect to automobile accidents and homicide. In 1934 there were more than 12,000 homicides in the United States, which, they say, "is a shocking record and places the country in the unenviable position of being the most lawless nation in the world"; and they contrast this, which gives a rate of 9·5 per 100,000, with a rate of 0·5 per 100,000 in England and Wales. Before priding ourselves too much, we should reflect that England and Wales is, areally speaking, a very small country indeed.

The authors comment with almost equal severity on the 34,000 deaths in 1934 due to automobile accidents, giving a rate more than twice that of England and Wales. But they note that 75 per cent of the world's motor cars are owned in the United States, so that we have certainly nothing to be proud of.

The volume is a most useful contribution to the literature of demography.

M. G.

Les Classique de la decouverte scientifique

(1) Traité élémentaire de chimie de Lavoisier
Pp. xxxviii+191+2 plates.

(2) Leçons de philosophie chimique
Par J.-B. Dumas. Pp. xxviii+270+2 plates.

(3) La synthèse totale en chimie organique
Mémoires de MM. Wöhler, Gerhardt, M. Berthelot, Le Bel, Van't Hoff, Jungfleisch, Ladenburg, Pasteur. Préface et commentaires par Marcel Delépine. Pp. viii+144+8 plates.

(Paris: Gauthier-Villars, 1937.) 21 francs each.

In reprinting these three classics of French chemistry with introductions, an important service has been rendered to the study of the history of chemistry.

(1) The famous "Traité" of Lavoisier, with an introduction by Le Chatelier, is reprinted in part only, but the important sections have been retained. The first part, giving the theoretical views of Lavoisier, has been reprinted in full; the second part of the original work, containing tables of compounds, has been omitted entirely, which has resulted in a few important sections being wanting, and a third part, dealing with apparatus, has been abridged. The illustrations have been incorporated in the text. The present work will serve the needs of students but it cannot be regarded as a critical edition. No indication is given as to which edition of the original has been followed for the text, and the title-page as reproduced does not correspond with either of the editions of 1789.

(2) The work by Dumas has been reprinted in full, with an introduction by G. Urbain; it is essentially historical and is still of considerable value. The style is lively and the choice of subjects is an excellent one. This volume will not only be read with profit by students but also will be useful to specialists.

(3) The volume on organic synthesis, with an introduction by M. Delépine, contains a very appropriate choice of texts in French, beginning with extracts from the registers of the Academy dealing with experiments of Bourdelin, extracts from the paper by Rouelle on urine (in which urea is first described) and from the paper describing the work of Fourcroy and Vauquelin in which this substance is first isolated, a translation of Wöhler's paper on the synthesis of urea, extracts from Gerhardt's "Traité", long extracts from Berthelot's "Chimie organique fondée sur la synthèse" and other publications by Berthelot, papers of van't Hoff, Le Bel, Jungfleisch and Ladenburg, and notes on the work of Pasteur and recent publications.

The three volumes contain portraits.

Science (K'o Hsüeh)
Vol. 22. Nos. 1 and 2 (January–February, 1938). (Shanghai: Science Society of China, 1938.) 50 cents (6*d*.).

At this time of unparalleled unhappiness for China, it is particularly interesting to see that scientific work is going on and that sufficient support is available for the circulation of a monthly journal very similar in its aims and format to Nature.

The January–February number, which lies before us, opens with a translation of the Mather Lecture of the late Right Hon. Ramsay MacDonald, published in Nature of October 30 of last year. This is followed by more specialized articles, such as a mathematical paper by Mr. H. C. Wang and an account of work on pentosan fermentation by Mr. C. L. Kuo. Anthropology is represented by an especially interesting review of the geographical distribution of the "Jew's Harp" in the Orient, based on a good deal of British field work as well as on Mr. H. Liu's own researches and drawing upon the descriptions of the instruments in classical Chinese literature. Another interesting contribution is from Mr. C. F. Hsü, who lists a further thirty indigenous Chinese drugs, giving their names, characteristic place of origin, traditional therapeutic use and the nature of the active principles found in them by modern chemical methods. An appeal is made to botanists to help to identify these plants which have been known for so many centuries in the Chinese classics.

Besides these articles there are accounts of contemporary events such as the Galvani celebrations at Bologna, the ceremonies attending Prof. H. Wieland's sixtieth birthday, and various congresses. Translations of certain reviews from Nature are also given.

The journal is printed in the modern 'scientific' style extremely well and gives an excellent impression. It should be realized that scarcely twenty years have passed since Western science began to be studied seriously in China. The application of Western science to Chinese conditions is by no means easy, since a large body of men educated in this tradition has not yet grown up. Moreover, the glaring necessities of the social situation require an emphasis on studies of immediate practical importance. Chinese scientific men are thus especially well aware of their social responsibilities. The recent discussions in Nature of such problems, having been in the minds of Chinese scientific workers for many years past, will find a very sympathetic understanding in China.

G. D. Lu.

Naturwissenschaftliche Erkenntniss und ihre Methoden
Von M. Hartmann und W. Gerlach. Pp. v+70. (Berlin: Julius Springer, 1937.) 2.40 gold marks.

Two addresses on the origin and methods of progress in biology and on theory and experiment in the exact sciences, delivered in September 1936 by Prof. Hartmann of Berlin and Prof. Gerlach of Munich before the Gesellschaft Naturforscher und Ärzte have been issued in pamphlet form, the second with considerable additions extending it to 49 pages as against 21 for the first. The aim of both addresses is to show that the methods by which science is advanced are the same in principle in all fields. In biology the methods are illustrated by the development of the chromosome theory of heredity, and in physics by the ways in which the detailed study of the physical memoirs of the last hundred years rather than philosophical discussions have made progress possible. Many examples of the way in which theory and experiment have reacted fruitfully on each other and stimulated growth are given by Prof. Gerlach, some taken from the newer, but more from classical physics.

Photographic Measurements of the Great Aurora of January 25-26, 1938

By Prof. Carl Stormer, Institute of Theoretical Astrophysics, Blindern, Oslo

THE great aurora of January 25–26 last was observed and photographed from my nine photographic aurora-stations in southern Norway. From $18^h 16^m$ until $6^h 7^m$ G.M.T., about 1,390 photographs were taken, of which about 710 were successful. Among these, there are 95 sets taken simultaneously from two stations, 48 from three and 14 from four, to determine height and position. Furthermore, about twenty spectra were secured. Besides this, I received about 180 letters with observations from different parts of Norway and about 20 from abroad. The working up of this extensive material will take a long time, but some preliminary results already obtained may be of interest.

My assistant, O. Hassel, who works without telephonic connexion with the other stations, began to take pictures as early as at $18^h 16^m$ G.M.T. A fine series of about sixty pictures had already been taken when the other stations began their work at $19^h 40^m$ G.M.T. Clouds at the eastern stations prevented good simultaneous pictures being obtained before $20^h 11^m$, but from that moment until dawn photographs were taken in rapid succession as fast as possible from all stations connected by telephone. The stations were combined as two sets. Each set, with the main station in Oslo, had up to three secondary stations, and the two sets worked independently of each other. The work was directed from the main stations in Oslo.

Twenty-one sets of simultaneous pictures have so far been measured and calculated. Some of the results are here brought together. Fig. 1 represents the aurora towards the south photographed from the Tömte station at 21.40.09 G.M.T. Simultaneous pictures were taken from Oslo and Oscarsborg. The arc near the southern horizon was green and persisted for a long time as the southern boundary of the aurora. Above it are seen rays which were of red colour. For a long time the northern half of the sky was quite free from any aurora. With the base-line Oscarsborg–Tömte, 73.7 km., the following heights were found: Lower border of the green arc, about 95 km. Base points of rays, from 150 to 200 km.: summits, from 500 to 600 km. The whole aurora was lying in the earth's shadow. The geographical situation of the rays measured is seen on the accompanying map (Fig. 2) over Denmark.

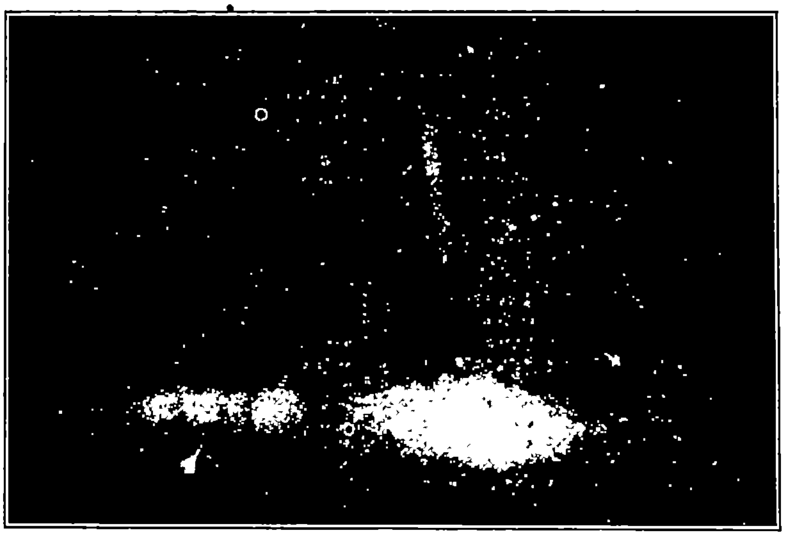

Fig. 1.

Aurora in the south photographed from Tomte, north of Oslo, at 21.40.09 G.M.T.

The green arc was lying under the base points of the rays. The further extension of the arc eastwards and westwards could be found from single pictures taken a little before, or after, the set mentioned, the height being supposed to be 95 km. The arc was sometimes single, sometimes double, and stretched from Ösel over Denmark to the northern part of Ireland, as seen on Fig. 2.

At the same time, two other rays were photographed simultaneously from Askim and Lillehammer. With this base-line, of 173 km., the base points of the rays were found to be at about 106 km. and 108 km., and the summits about 500 km. and 540 km.

All these rays were lying in the earth's shadow, and their great length, up to 400 km. and more, is quite astonishing; it seems to indicate that the high atmosphere is lifted up by the action of the big aurora, like the lifting up by the action of the sunlight in other cases.

At $21^{h}\ 41^{m}$ G.M.T., the ray-summits had neared the magnetic zenith in Oslo. With the base Oslo–Lillehammer, 133 km., the summits were again measured and gave heights up to 500 km.

A fine corona next developed. The point of radiation found from the Oslo picture at 21.41.40 G.M.T. could be measured with a precision of ± 0·2° in altitude and ± 0·6° in azimuth, to altitude 70·0°, azimuth 6·4° east of south. At 21 45.34 the base points of the rays of the corona in the east were measured with the base-line Oscarsborg–Tømte, and found to be 95–105 km. (parallax, 15–20°).

During the later maximum, near midnight G.M.T., new determinations of high rays were made and heights even to about 650 km. were found for rays lying in the earth's shadow, a very remarkable fact. At $0^{h}\ 14^{m}$ G.M.T. the whole heavens was filled with a gorgeous corona, and it was difficult to find parts of it characteristic enough to be measured. Only the base points of some rays towards the east against the dark sky behind could be measured, and a height of about 95 km. was found. During this corona, which may be characterized as the maximum activity of the aurora in Norway that night, my assistant, Mr. Tjönn, at my station on Njuke Mountain in Tuddal, 733 metres above sea-level, reported that he heard sounds with the aurora. He says in a letter to me :

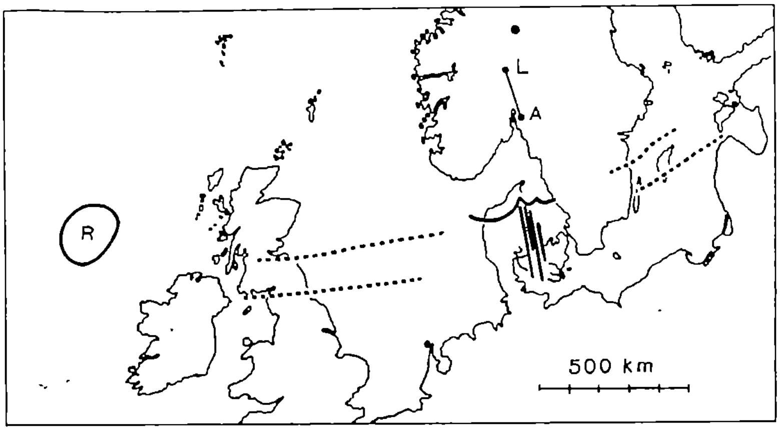

Fig. 2.

Geographical situation of auroral arcs and rays at about $21^{h}\ 40^{m}$ G.M.T. and of a red spot (*R*) at $0^{h}\ 35^{m}\ 45^{s}$. The dotted lines are found from single pictures supposing the lower border of the arcs equal to 95 km. *L–A* is the longest base-line, Lillehammer–Askim, 173 km.

"During the imposing display of this big corona, where the whole heavens was like an ocean of flames, my assistant and I heard a curious sound which came from above, first from the south-west, then from the zenith and at last from the north-east. The sound lasted about ten minutes, rose to a maximum and fell down again, following the intensity of the aurora. I had the impression that it had something to do with the white rays. At that time I had taken off the earphones from my ears (when I had them on, I heard nothing of this sound) and went some steps aside to hear it better ; that the sound came from the telephone is quite excluded. The sound is difficult to describe, it was similar to the sound from burning grass and spray. On the mountain it was absolutely quiet, no sound coming from wind, waterfalls, telegraph lines or motors. Both my assistant and I heard it and are quite convinced that the sound was real. On the summit of the mountain where we had our station, only a few fir trees grow. Under us on all sides we had the forest."

The same sound was heard independently of Mr. Tjonn, down in the valley Tuddal, by Öystein Reisjaa, who in a letter has confirmed in all details the description given by Mr. Tjönn. When Mr. Tjönn heard the sound, he telephoned to me ; but I was so occupied by securing height determinations of the big corona that I did not pay sufficient attention to his call. On account of the great height of the aurora, it is clear that the sound could not come from the aurora itself, but from lower parts of the atmosphere ; but where its origin was future observations may decide.

A very characteristic feature of the aurora of January 25–26 was the red colour, which appeared both as diffuse surfaces occupying sometimes vast areas of the sky, and as a red glow at the top of the aurora, well seen from stations so far south as northern Africa and so far north as middle and northern Norway. This fact made it most probable that the red coloration reached enormous heights, and at $0^{h}\ 35^{m}\ 45^{s}$ G.M.T. we also succeeded in getting simultaneous pictures of a red spot in the west-south-west from the three stations Askim, Oslo and Lillehammer on panchromatic plates, Agfa ISS. As the base-lines were almost normal to the direction to the spot, the determinations are fairly trustworthy. We found for the lowest part about 350 km., and for the summit, almost 700 km. above the earth. The spot was situated about 1,500 km. away over the Atlantic Ocean north-west of Ireland, and was quite in the earth's shadow. I am sorry that the weather prevented us from measuring the sunlit parts of this aurora early in the evening. Records of auroral heights would probably have been the result.

Among the spectra taken by my assistant, Herlofson, only a few need be mentioned. On the same Agfa ISS plate were taken two spectra when the spectrograph was pointed towards the green arc in the south mentioned in the first part of this report. They show the green line 5577 A. as the strongest; then come with decreasing intensity the lines 6300 A., 6550 A. and 4278 A. On the same plate were taken two spectra when the spectrograph was pointed towards red areas. They show 6300 A., by far the strongest, next 5577 A. and faint traces of 6550 A. and 4278 A.

On Agfa red ultra-rapid plate was taken with the same spectrograph a spectrum of the red colour in the southwest between 0^h 10^m and 0^h 30^m G.M.T. Here 6300 is again by far the strongest line, then 6550 and 5577 about equally strong, and traces of 4278. On the same plate were taken spectra of pulsating auroras and corruscations between 2^h and 4^h G.M.T., situated in the height interval from 90 to 120 km. Here all four lines have about the same intensity.

Photometric measurements of these spectra will be made later.

Medical Research in Great Britain

THE report of the Medical Research Council for 1936–37* gives, in summary form, an account of the researches carried out by members of its staff, either at the National Institute for Medical Research or in external institutions, as well as by the numerous investigators, working in different laboratories, who receive grants-in-aid from the Council. In this report, separate sections are devoted to the work carried out by members of the Council's staff in external institutions, instead of its being included in the sections also describing the investigations aided by grants, in order to give a truer picture of the organization of the Council's activities.

Lord Mildmay of Flete, treasurer of the Council, resigned his membership during the year; Mr. Goodenough was appointed to succeed him. Sir Thomas Lewis and Sir David Wilkie retired in rotation and were succeeded by Prof. Gask and Prof. Witts. The Council has made appointments to Dorothy Temple Cross research fellowships, to research fellowships in tropical medicine and also to Rockefeller medical fellowships. It will be recalled that last year it was announced that the Rockefeller Foundation had suspended the arrangement under which the Council awarded these fellowships, as it wished to concentrate its activities on certain selected fields of medical research: the Foundation has, however, now generously agreed to restore and augment the former arrangement. The Council has continued to maintain close touch, at relevant points in its work, with the Government departments concerned with questions of health and has also been closely concerned with international health work under the League of Nations, and especially with regard to questions of nutrition and of biological standards, upon the Commissions dealing with which it is directly represented.

The need for additional laboratories for work on chemotherapy and biological standards and for nutritional studies as well as to relieve the present overcrowding at the National Institute for Medical Research has led the Council to consider the possibilities of development at the present site at Hampstead and at the site of the farm laboratories at Mill Hill. Owing to the fact that the Hampstead site has been reported on as unsuitable for further development on the scale which is now in view, even without allowing any margin for future expansion, the Council has decided in principle to abandon this site and to concentrate the whole of the National Institute at Mill Hill. A final decision can be taken only in the light of a definite estimate of the cost, based on the detailed plans which are now being worked out. If the project can be undertaken at once, it should be possible to complete it within about two years, and to provide additional accommodation for some purposes at an earlier date.

The grant-in-aid provided by Parliament for the expenditure of the Medical Research Council was greater by £30,000 than the amount in the previous year, the difference representing special provision for the development of research work in chemotherapy. Chemotherapy is the treatment of infective diseases by the administration of chemical compounds synthesized in the laboratory, which have been found to have specific actions on the infective organisms associated with these diseases. The principal successes of this form of treatment have so far been in infections with spirochætes and protozoa rather than with bacteria, in venereal and tropical diseases rather than in the bacterial infections common in a temperate climate. Quite recently, however, success has attended the use of the sulphanilamide group of drugs in streptococcal and other infections, thus opening up a new field of chemotherapy, which is being rapidly and effectively developed.

* Committee of the Privy Council for Medical Research. Report of the Medical Research Council for the Year 1936–37. Pp. 165. (London: H. M. Stationery Office, 1938). 3*s*. net.

Although this is the usual sense in which the word "chemotherapy" is employed, there is a much wider field of medical treatment in which advance depends on the same kind of investigation, made by chemists and biologists working in close collaboration. In this field is included the discovery of chemical substances which have specific actions on certain bodily functions, and therefore great value in the systematic treatment of disease The Council points out that the discovery of chemical compounds of this nature has depended almost entirely on German science and industry, and still so depends, although several fundamental discoveries were made in Great Britain. There is therefore great need for further research in Great Britain aimed at the discovery of new chemical substances of therapeutic value, and strong reason for developing a national scheme of investigation not unworthy of comparison with the work that is done abroad, especially considering that the British Empire is the chief consumer of drugs used in the treatment of tropical diseases. The financial requirements of an effective scheme are too large to be met from the ordinary resources for medical research, so that it can only be supported by funds specially provided as a matter of national policy. In Germany, the research work has been mainly carried out in institutions maintained by manufacturing chemists: in Great Britain the interests of the larger firms have lain in other directions, and the smaller firms have been content to act as agents for the foreign producers. In the absence of the necessary expansion of chemical industry, the only possibility of securing that Great Britain takes its proper part in this matter, in relation to its imperial responsibilities, is a national scheme supported from public funds.

For some years, the Council has supported research work on chemotherapy at different centres and valuable results have been obtained; witness the recent discovery of the trypanocidal properties of compounds with terminal iso-thiourea and amidine groupings. Notwithstanding the results obtained under the present scheme, it had become clear that improved research facilities were needed to secure substantial advances in chemotherapy from the point of view of the ultimate practical effect on diseases inaccessible to other forms of treatment, and especially on the major problems of protozoal infections in the tropics. It is considered that a central research laboratory is an essential factor in a national scheme: it will provide for the close association of the biological investigators with those engaged in the synthetic production of new compounds: and it will provide mass data from which it may be possible to discover laws relating chemical structure to therapeutic effect, so that research in this field will become less empirical than it is at present.

The main part of the report is devoted to short accounts of the researches carried out by members of the Council's staff or by workers assisted with grants-in-aid; but certain subjects are selected for more detailed consideration in the introduction, of which two have been referred to above. Among others may be mentioned influenza and the study of viruses, the surgery of the heart, the causes of mental defect, the role of salt in the body, the diagnosis of cholera and the experimental study of leprosy. It is now known that the virus of influenza is multiple, that responsible for the 1933 epidemic being of a different strain from that isolated in the 1936–37 epidemic. Hence, if vaccination is to have the best chance of success in any future outbreak, it will be necessary to choose an inoculum made from a virus belonging to the same immunological group as that responsible for the immediate outbreak. Experiments with ferrets suggest that such vaccination may successfully prevent the ordinary human contact infection. The discovery that many viruses will grow in the chorio-allantoic membrane of the developing chick provides an experimental method of research into their properties, which is simpler and more precise than that involving inoculation of laboratory animals. It is possible that the egg-culture technique may be used in the future for producing vaccine to protect against smallpox on a large scale, thus superseding the lymph of infected calves.

An interesting account is given of recent experimental work on the surgery of the heart and its application to cases of heart disease in man. Vascular obstruction in the heart cannot ordinarily be remedied as in most other organs by the development of a collateral circulation: it has been found, however, that the great omentum can be brought up from the abdomen through the diaphragm and secured to the heart, when new blood vessels will grow into the heart muscle from it. Several patients have now been operated on and only one may be considered to have died as the direct result of the operation; the survivors are all improved and some formerly bed-ridden patients are now leading a life of normal activity. About a quarter of the patients operated on only survived a few months, but it is pointed out that individuals suffering from diffuse disease of the vessel walls in the heart are in any event liable to sudden death; two in fact died suddenly a few days before the date on which the operation had been arranged for them.

The discovery that the bacillus of rat leprosy can be transmitted to the Syrian hamster, has been followed by the announcement from Palestine that this species can be similarly infected with the causative organism of human leprosy. This work should provide the basis of a new attack on the problems of this disease, and, in particular, make possible the experimental study of the treatment of leprosy by chemotherapeutic methods.

A few only of the subjects dealt with in the report have been selected for notice in this review: for a fuller picture of the Council's activities reference must be made to the original. It may be mentioned that full titles and references to the original papers published by members of the Council's staff and other investigators are given throughout the report, so that those interested can easily obtain the further details they require.

The Linnæan Tradition

FOUNDED ten years after the death of the celebrated Linnæus, the Linnean Society of London has for the past hundred and fifty years carried on the work he initiated in systematic botany and zoology. The anniversary was celebrated in London by appropriate meetings on May 24–27. Without any doubt the founding of the Society was due to the presence of the Linnæan Collections in England in 1784, in which year they had been received by purchase from Linnæus's widow by James Edward Smith, a medical student then twenty-four years of age. That close contact with the materials used by the great Swede resulted in the English naturalists adhering very closely to what may be called the Linnæan tradition; and although the systems used by Linnæus have been greatly changed or superseded, it is significant that his authority and influence are still felt strongly to-day.

The tradition left by Linnæus was indeed a great and a worthy one. Despite the carping criticisms of certain historians, there is no doubt at all that Linnæus wrought a great and fundamental work in both botany and zoology. Concentrating his efforts on the classification and description of plants and animals, he did the task most needed for his time; leaving a vast body of completed work, and, as the result of his deep and sincere thought, methods which are followed in the main by taxonomists to-day. Looking across two centuries, we can visualize that short sturdily built man with his keen-sighted brown eyes and his open and pleasant face, who worked from boyhood to old age with singleness of purpose towards one objective—to know and classify all forms of living organisms. No living organism can be named correctly until it is known; none known properly until it is classified correctly.

Linnæus's achievements in botany and zoology can be gauged rightly only when considered in relation to the states of those sciences at the time when he worked. He came at a time when Western naturalists had succeeded in disentangling themselves from the ancient authority and superstition that had clung to them long after the Renaissance. Men had turned from the authority of books to study Nature; from travels and exploration more new plants and animals were becoming known each succeeding year; attempts were being made to present in systematic form the knowledge then extant; but the net result had been a chaos in which each worker had put forward his own ideas of system and nomenclature.

Coming at the very time when he was urgently needed, Linnæus, clear-headed, practical, imaginative, resolved that chaos into order. Although so early as 1738 he had published in "Classes plantarum" a sketch of a natural system in botany, and throughout his life continued to elaborate it, his botanical works were always arranged according to the sexual system, which he had devised when he was twenty-four years of age. His reason for adhering to that system was a sound one: at the time he worked, an insufficient number of plants were known to found properly a natural system. Nevertheless, his own system brought together automatically some of the natural groups; and when the rise of the natural system began with the work of the de Jussieus, Robert Brown and others, much of Linnæus's work on genera and species still held good. In zoology, also, Linnæus's influence continues in spite of changes of system.

The Linnean Society's early history reflects most clearly that almost religious adherence to the Linnæan tradition; but the rise of the natural system in botany, the impact of the Darwinian theory of natural selection, the influence of the great school of German physiological botanists, or the specialistic developments of modern biology, have not obliterated that tradition. None of these waves of influence could or can sweep away the ultimate necessity of presenting the facts of Nature in taxonomic form. Under his will, Darwin left a sum of money to be devoted to the compilation of a great index for the use of taxonomists, the "Index Kewensis"; the aim of the German physiologists was to find a better basis of taxonomy (one of the negative results of which is that to-day real systematic botany is but scantily touched upon in British universities); and the efforts of the ecologists, geneticists and cytologists can have but one real object—the ultimate reclassification of living organisms.

Among the tendencies of the present time, it is possible to detect an impatience with the existing forms of taxonomy; but any attempt to alter such forms without very profound consideration and fair trial would seem likely to lead to a chaos similar to that from which Linnæus rescued the learned world. Often without being able to read with any ease the Latin works of the older naturalists, some of the modern workers appear to be inclined to cut adrift entirely from the past. The remedy surely lies in a more careful consideration of the philosophical ideas upon which all taxonomy must be based.

A Discontinued Darwin Medal

By T. E. James

THE rise and mutual development in Great Britain of provincial natural history and literary societies, microscopical clubs and field clubs is one of the stories of nineteenth century science that scarcely requires iteration. Yet in regard to one of these, the Midland Union of Natural History Societies, an amalgamation of 1878, due in the main to the efforts of Mr. Lawson Tait, F.R.C.S., of Birmingham, there is a connexion of Darwinian interest in the Union's institution of a Darwin Medal, which in course of time has lapsed in award, and possibly is now altogether out of mind.

The medal bore on the obverse the portrait-bust of Charles Darwin in bas-relief and the reverse a branch of coral; while the medal itself was the work of Joseph Moore (1817-1901), a well-known medallist-sculptor and die-sinker in Birmingham.[*] Why the award of this medal ceased will be considered presently. Apart from the Royal Society's Darwin Medal (the first award of which was not made until 1890), there would appear now to be no medallic gift in Great Britain which periodically commemorates the researches of the great naturalist in this way.

The idea of an amalgamation of the numerous scientific and literary societies already existing in various parts of the Midland counties took practical shape in 1878 as above mentioned, and a journal called the *Midland Naturalist* was started as the organ of the Union; the journal appeared successfully down to the end of the year 1893. It was an effective and highly popular medium of intercommunication, but like other official fusions of the period, strength of membership carried latent weaknesses. The magazine eventually became an onerous task, its issue resting on the efforts of the zealous minority.

Returning to the Darwin Medal of the Midland Union, it appears that at the annual meeting held in 1880 at Nottingham, a suggestion was made by Mr. W. Jerome Harrison for the foundation of a yearly prize which should have as an objective the encouragement of original research connected with the natural history of the Midlands. Regarded favourably, it was unanimously agreed to institute an annual Darwin Prize of the value of £10, to include a gold medal denominated the Darwin Medal, for a paper embodying original research contributed by a member of the Union for publication in the *Midland Naturalist*. Incidentally, it may be said that Charles Darwin was a subscriber from the first to this publication.

DARWIN MEDAL OF THE MIDLAND UNION OF NATURAL HISTORY SOCIETIES.

Steps were taken to acquaint Darwin with the proposal and to ask his permission to adopt his name. Darwin replied as follows:

> "I request that you will be so good as to inform the members of the Committee that their wish to name the medal after me is a very great honour, which I gladly accept. It is particularly pleasing to me to have my name connected, in however indirect a manner, with a scheme for advancing science—the study of which has been my chief source of happiness throughout life."

---

[*] Joseph Moore also designed a medal for the British Association meeting at Birmingham in 1849 and at Cheltenham in 1856.

This cordial letter is not recorded in the "Life and Letters"; but somewhere perhaps the original may be in existence.

Regarding the provision of regulations for the "Darwin Prize", it was decided that the subjects for each of the three years ensuing should be geology, zoology and archæology. The following committee of five adjudicators was chosen: Dr. Thomas Wright, the Rev. George Deane, Prof. Charles Lapworth, J. J. Harris Teall (afterwards Sir Jethro Teall) and W. Jerome Harrison. The first recipient of the gold medal, for the year 1881, was Edward Wilson, of Nottingham, for his paper "The Permian Formation in the North-east of England". The award for the year 1882, in zoology, went to Prof. A. Milnes Marshall, M.D., and W. P. Marshall, M.Inst.C.E., for their joint paper on the "Pennatulida". Space forbids naming the adjudicators. The medal was presented at the annual meeting held at Tamworth in June 1883.

At this meeting it was reported also that a bronze copy of the medal had been sent to the family of the late Charles Darwin, and that Mr. W. Erasmus Darwin, writing from Basset, Southampton, on December 14, 1882, had expressed the opinion that it embodied a striking likeness of his father, who had much appreciated its foundation.

Awards continued, mostly yearly, but always subject to the receipt of meritorious papers. Mention may be made of the annual meeting of 1889, held at Oxford, with Mr. (now Sir Edward) E. B. Poulton, F.R.S., as president of the Union. His address bore the title "Theories of Heredity". We hear of "trenchant criticism" of the word "heredity" by Lawson Tait, and a "lively passage of arms" thereon with Francis Galton. The Darwin Medal for the year was handed to T. W. Walker, for a thesis on a geological subject.

So far back as 1882 a note of warning had been given in the *Midland Naturalist* that an endowment fund of £250 would be required if the gift of a gold medal was to continue as a permanent memorial. Alas! this object was never achieved; the Union sailed over uncharted and uncertain waters, and some indeed of its constituent bodies were bad sailors in Darwinian days. The *Midland Naturalist* ceased publication at the close of 1893, and the Darwin Medal became a final award in 1895 with its allocation to Dr. Walter E. Collinge, now keeper of the York Museum, for studies in comparative anatomy.

Obituary Notices

Mr. Hugh Ramage

THE death of Mr. Hugh Ramage, on April 16, at seventy-three years of age, will be deeply regretted by all who knew him. He was one of the most unassuming of men, yet his work in certain fields of spectroscopy was of a very high order, and his devotion to these studies in the leisure hours of a busy life manifested a spirit of self-sacrifice in the pursuit of scientific knowledge not often found at any time.

Mr. Ramage was born on March 31, 1865, at Wolverton, Bucks, but both his father and his mother were natives of Catrine, Ayrshire. He left school at twelve years of age, and a year later, after his parents had removed to Crewe, he entered the L.N.W.R. carriage works there in the telegraph office, his duties being to work the single needle telegraph instrument. While in this position, and afterwards when he became an apprentice in coach-making, he attended evening classes in elementary scientific subjects and mathematics at the Mechanics' Institute. Probably on account of these studies, he was eventually transferred to the laboratory of the locomotive works and became engaged in analytical work. When twenty-one years of age, he entered for the annual competition for National Scholarships or Royal Exhibitions, then awarded on highest successes in the Science and Art Department's examinations. As the result, he obtained a Royal Exhibition tenable at the Royal College of Science, Dublin, which he entered in October 1886.

After completing his course at the Royal College of Science, Mr. Ramage returned to the Crewe laboratory in 1889 under Joseph Reddrop, and while there carried out investigations on the bismuthate method of estimating manganese and the estimation of phosphorus and carbon in mild steels. He left Crewe in 1891 to become demonstrator in chemistry under Prof. (afterwards Sir Walter) Hartley at the Royal College of Science, Dublin; and in the following year he began to assist Sir Walter in researches on flame spectra. One of the chief objects in view was the study of Bessemer flame spectra; and the results obtained were valuable contributions to the knowledge of the thermo-chemistry of the Bessemer process. It was in conjunction with Mr. Ramage that Sir Walter Hartley discovered the existence of the bands in the flame spectra of many metals and from a study of these was able to draw important conclusions about the relation between the band and line spectra of the same element.

Mr. Ramage's introduction to the use of the spectroscope in chemistry in association with Sir Walter Hartley determined his main scientific interests and activities throughout the rest of his life. In 1899 he left Dublin and went to Cambridge as a research student, Prof. Liveing giving him facilities for work on the oxyhydrogen flame spectra of metals, especially the band spectra of copper, silver and gold, but also of other elements, and to study homologous lines in spectra and relationships between wave-length or wave-number and atomic weight. In his ninth term he submitted two theses to the Board of Studies and obtained his degree upon them. Three years later, in 1904, he was appointed organizer of higher education and principal of the Technical Institute at Norwich, out of which developed the Norwich Technical College, of which he was the principal until his retirement in 1930.

Mr. Ramage was the author, or joint author, of a number of papers published in the proceedings or transactions of societies and in scientific journals. Reference has already been made to his work with Reddrop, with whom he was associated in his first paper published by the Chemical Society in 1895, on the volumetric estimation of manganese by oxidation with sodium bismuthate, which is now in general use. From that date until 1901 he was the joint author, with Sir Walter Hartley, of fourteen papers contributed to the Royal Society, Chemical Society, Iron and Steel Institute and other societies, on spectrographic analysis of various minerals and metals and related subjects. Among the subjects of similar papers of which he was the sole author are the spectra of potassium, rubidium, cæsium and their mutual relations, abnormal changes in some lines in the spectrum of lithium, and the distribution and spectra of metallic vapours in electric sparks. He also discovered that Norwich flue-dust was a source of gallium.

In recent years, Mr. Ramage devoted chief attention to the use of the spectroscope to biology and medicine, and his researches in this field are of particular importance. Some of the most interesting of these were published as communications to NATURE, and others appeared in the *Biochemical Journal*. The first account of results obtained by Mr. Ramage in his extension of spectrographic analysis to vegetable and animal matter seems to have been given by him in NATURE of April 20, 1920. This was followed, in the issue of August 23, 1930, by a communication on such an analysis of mushrooms, which showed that each part had a high potassium and a low calcium content. Copper and silver were also shown to be contained in different parts of a mushroom. (In August of last year Mr. Ramage extracted from half an ounce of dried mushrooms in powdered form a tiny pellet of silver and a similar one of copper.) In NATURE of November 1, 1930, a joint communication from Prof. Munro Fox and Mr. Ramage summarized the results of a survey of animal tissues with the view of detecting and analysing quantitatively those of the less common elements contained in protoplasm and its products capable of being investigated by spectrographic methods. A paper on this subject by Fox and Ramage was published in the *Proceedings of the Royal Society* in the following year. It was shown by these studies that manganese was widely distributed and that the manganese content of animal tissues varied with the locality in which a given species of animal lived. Further work showed that strontium occurred in the genital duct of the edible snail and that manganese was a prominent element in its liver. Copper and iron were always detected; and silver was present in the kidney and liver of all crabs and lobsters examined. Similar methods were applied to the study of the composition of human tissues, the results of which appeared in the *Biochemical Journal* and the *Proceedings of the Royal Society*. Among other results, this work led to the first description of the presence of barium in the human choroid.

The essential importance of small amounts of mineral constituents in soils, as affecting the growth of both plants and animals, is now fully recognized, and the researches carried out by Mr. Ramage himself, and in association with others, upon the occurrence of such elements in plant and animal tissues have proved to be of greater practical value than was ever anticipated by him. He played an important part in the study of a deficiency disease of sheep in Australia, which ultimately proved to be curable by cobalt, by virtue of his discovery that the soil in the affected areas was deficient in this element. The sole motive of his scientific work was to increase his own knowledge of natural actions and phenomena, and to present the world with the results obtained, whether they were of practical use or not. In this respect he represented the noblest type of the scientific spirit.

While attending the Toronto meeting of the British Association in 1897, Mr. Ramage met Miss Winifred Pye-Smith, who became his wife in 1904 and survives him, with one son and one daughter.

Sir Wolseley Haig, K.C.I.E., C.M.G.

WE regret to record the death of Sir Wolseley Haig, distinguished as soldier, administrator and orientalist, which took place on April 28, at the age of seventy-two years.

Thomas Wolseley Haig was a son of Major Robert Wolseley Haig, of the Royal Artillery and fellow of the Royal Society, and was born on August 7, 1865. He was educated at Wellington College and Sandhurst, joining the Seaforth Highlanders in 1884. He transferred to the Indian Army and was engaged in the suppression of the dacoits of Upper Burma. His appointment in 1892 as a member of the Berar Commission, which was entrusted with the Assigned Dominions of the Nizam, brought him into close touch with the life of the Deccan and turned his interests to the study of its history and linguistics. After holding various administrative posts there, he entered the Political Department of the Government of India in 1901, serving at Hyderabad, at headquarters, and at Alwar, where as political agent he exerted great influence over the somewhat difficult Maharaja. His final term of service in the East, from 1910 onward, was passed mainly in Persia. He served in a consular capacity at various posts, including Baluchistan, Khorasan and Ispahan, to the last-named of which he was transferred in 1916, and where he was associated with General Percy Molesworth Sykes, who speaks highly of his abilities and achievement in dealing with Eastern peoples in his "History of Persia". In 1920 he retired, having received the orders of the Star of India, St. Michael and St. George, and the British Empire. In 1922 he was created K.C.I.E. In 1923 he accepted an heraldic appointment in Scotland. He resigned the office of Albany Herald in 1935 on the ground of ill-health.

As an oriental scholar, Sir Wolseley Haig will be remembered chiefly for his contributions to Indian history and for his detailed knowledge of Moslem rule. As a translator his version of Badaoni's history, one of the chief sources for Akbar's reign, is the standard of reference. He also translated the *Burhan-i-Maasir* of Tabatabai, the principal source for the Nizam Shahi dynasty of Ahmadnagar. On his return to England, Sir Wolseley was appointed professor of Arabic, Persian and Hindustani at Trinity College, Dublin, and later was lecturer in Persian in the School of Oriental Studies, London. He was also joint editor of the "Cambridge History of India", the third and fourth volumes, covering the whole Moslem period, being allotted to him. The third volume was largely his own work; but owing to a breakdown in health, after he had planned the fourth volume and prepared voluminous notes, the completion of the volume fell to Sir Richard Burn.

News and Views

Prof. J. J. Abel, For. Mem. R.S.

Prof. John Jacob Abel, who has just been elected a foreign member of the Royal Society, is the doyen of American pharmacologists. He is one of the best known and widely beloved personalities in medical science, in his own and other countries. After graduation, he worked under C. Ludwig in Leipzig and O. Schmiedeberg in Strassburg. Returning to the United States, he became professor of pharmacology at Ann Arbor, Michigan, migrated from there in 1893 to be the first professor of pharmacology at the Johns Hopkins Medical School, Baltimore, and held this chair with great distinction for nearly forty years. Prof. Abel's direct contributions to science have been chiefly on the chemical side of pharmacology. He was the first to bring to practical completion the isolation of epinephrine (adrenaline); later he discovered the same substance in the skin glands of a South American toad, from which he also isolated the toxic principle 'bufagin'; and he was the first to crystallize insulin. Among many other achievements, he devised methods for studying the diffusible constituents of the living blood, and the reconstitution of its plasma after hæmorrhage. Even in his retirement he is actively engaged in new and important researches on tetanus toxin. Throughout medical science in the United States his influence has been spread by his pupils, inspired by the example of a long life of selfless devotion to the pursuit of knowledge.

Prof. N. E. Nørland, For. Mem. R.S.

An unusually wide circle among men of science, including mathematicians, astronomers and geodesists, will approve and appreciate the election of Prof. N. E. Nørlund to the foreign membership of the Royal Society. Prof. Nørlund has since 1923 been the director of the Danish Geodetic Institute, an office always previously held (as in the case of the Ordnance Survey in Great Britain) by a military officer. In recent years, he has undertaken a new first-order triangulation of Denmark, and in Greenland also he has instituted a new triangulation which will extend up to 76° N.—a most valuable contribution to the determination of the figure of the earth. In mathematics, his works include memoirs on the theory of difference equations in the complex domain; on divergent series; and on continued fractions. In astronomy, at the University Observatory of Copenhagen, he has worked especially on the errors which affect the meridian observations of fixed stars, and has also made an important study of the double star ξ Ursæ Majoris, concluding from a very slight perturbation in its orbital motions that it is a triple star, the observable pair having an invisible satellite. Prof. Nørlund has held many distinguished offices in his own country, and has played a prominent part in the international organization of science; he has presided over the Baltic Geodetic Commission, the International Time Commission, and the International Council of Scientific Unions. He is a foreign member of the Academies of Science in Paris, Rome (Lincei) and Stockholm, and an associate of the Royal Astronomical Society.

Prof. René Leriche

The Lister Medal for 1939, which is awarded in recognition of distinguished contributions to surgical science, has been awarded to Prof. René Leriche, professor of clinical surgery in the University of Strasbourg, and he will deliver the Lister Memorial Lecture in 1939 at the Royal College of Surgeons of England. Prof. Leriche, who was born on October 12, 1879, received his medical education at Lyons, taking his degree in 1906. In 1906–9 he was chief of the surgical clinic of the Lyons hospitals, and then became full surgeon. In 1920 he became lecturer in experimental surgery at Lyons, and has also held there the professorship of external pathology. In 1924 he was appointed to the chair of clinical surgery in the University of Strasbourg which he now holds. He was made an honorary fellow of the Royal College of Surgeons of England in 1937. Prof. Leriche is chiefly interested in the surgery of the stomach, bones, joints, the sympathetic system, and diseases of arteries. This is the sixth occasion of the award, which is made by a Committee representative of the Royal Society, the Royal College of Surgeons of England, the Royal College of Surgeons in Ireland, the University of Edinburgh, and the University of Glasgow.

Dr. D. T. A. Townend

DR. D. T. A. TOWNEND has been appointed Livesey professor of coal gas and fuel industries in the University of Leeds. After nearly four years of war service, Dr. Townend entered the East London (now the Queen Mary) College, London. He graduated in 1920 and then proceeded to the Department of Chemical Technology at the Imperial College of Science, London, for post-graduate study and research under Prof. W. A. Bone. He has since collaborated with Prof. Bone more particularly in investigating gaseous explosions at high initial pressures. Dr. Townend was awarded successively a Salters' research fellowship and a Rockefeller international research fellowship. He has been largely concerned in the equipment and organization of the High Pressure Laboratories at the Imperial College. Dr. Townend, who is a recognized teacher in the University of London, is an authority on combustion and high-pressure problems and has published many books and articles both independently and in collaboration with his colleagues at South Kensington.

U.S. National Academy of Sciences: New Members

AT the annual meeting of the U.S. National Academy of Sciences held on April 25–27, the following were elected foreign members: Prof. Alfred Fowler, emeritus professor of astrophysics, Imperial College of Science and Technology, London; Prof. Pierre Janet, professor of psychology, Collège de France, Paris; Dr. S. P. L. Sorensen, director of the chemical division of the Carlsberg Laboratory, Copenhagen; and Prof. D. M. S. Watson, Jodrell professor of zoology and comparative anatomy, University College, London. The following members were also elected: Prof. M. H. Stone, professor of mathematics, Harvard University; J. A. Fleming, Department of Terrestrial Magnetism, Carnegie Institution of Washington; Dr. C. D. Anderson, California Institute of Technology; Prof. G. W. Stewart, professor of physics, University of Iowa; Prof. Theodor von Kármán, director of the Daniel Guggenheim Laboratory, California Institure of Technology; Prof. W. K. Lewis, professor of chemical engineering, Massachusetts Institute of Technology; Prof. C. S. Marvel, professor of organic chemistry, University of Illinois; Prof. W. H. Rodebush, professor of physical chemistry, University of Illinois; Prof. W. H. Bucher, professor of geology, University of Cincinnati; Prof. L. J. Stadler, professor of field crops, University of Missouri; Prof. T. S. Painter, professor of zoology, University of Texas; Prof. W. de Berniere MacNider, professor of pharmacology, University of North Carolina; Prof. E. Adelberg Doisy, professor of biochemistry, St. Louis University; Prof. S. B. Wolbach, professor of pathological anatomy, Harvard University; Prof. L. L. Thurstone, professor of psychology, University of Chicago.

Metal-Mining Enterprise

SIR WARINGTON SMYTH was the first professor of mining at the Royal School of Mines, and his forty years of service coincide with one of the most momentous changes in the history of the world, namely, the growth of industry on a metallic foundation. Prof. S. J. Truscott showed, in his Warington Smyth Memorial Lecture delivered on May 5 (Pp. 38 + 2 plates. London: Macmillan and Co., Ltd. 1*s*. net)how to-day everything civilized man enjoys depends on metals; without them rapid transport, modern housing, preservation of foodstuffs, etc., are impossible. Metals are durable as contrasted with vegetable and animal products, which are used once, whereas metals can be and are refabricated. The annual production of fresh supplies of metal merely augments the amount already in use, an amount greater in value than the total of all other commodities utilized by man. Metals, with the exception of gold, are not found to any extent as native metal and have to be extracted from highly complex ores. The enterprise of the miner has made many valuable discoveries such as the Bessemer process for ferrous metallurgy, the McArthur cyanide process for precious metallurgy and the flotation process for the base metals, and probably the same enterprise will find a cheap method of producing the light metals such as aluminium and magnesium. Further enterprise has rendered available vast sources of minerals which would otherwise have remained valueless, and in addition has shifted the centre of production of certain metals, for example, copper, from one continent to another. As the result of the exploitation of these processes combined with similar advances in engineering technique, one part of gold in 200,000 is being won at a profit, and one hundred million tons of base metal minerals are being treated by the flotation process per annum.

Mining Engineering as a Profession

IN his presidential address delivered on May 19 to the Institution of Mining and Metallurgy, Dr. C. B. Kingston discussed "Mining Engineering as a Profession". He said that mining is essentially a man's job and offers a splendid career to the keen ambitious man who is not seeking security first but likes a spice of adventure and finds satisfaction in a constructive occupation that makes some definite contribution to the world's welfare. The training of a modern mining engineer should be based on a sound general education, as not only must he be a technician but also in addition a man of affairs, a competent negotiator and preferably a linguist. The technique of mining is difficult to define, as it is all-embracing in its requirements, but briefly it can be described as the application of all the applied sciences to finding, winning and subsequent preparation for the market of a mineral deposit. The increasing importance of metal in the world's affairs is creating further demands on a mining engineer's accomplishments in an ever-widening field of activity and with larger-scale operations than ever before. A study of history, ancient and modern, in terms of minerals is fascinating because the growth of nations and the cause of many wars cannot be dissociated from the possession or a determination to secure control of high-grade deposits of essential minerals. The question has been asked, "Who owns the earth ?", and the answer given is "The nation which controls the greatest mineral resources."

Roman Wroxeter

RECENT excavations on the site of the Roman city of Uriconium, which lies beneath the modern Wroxeter, five miles from Shrewsbury, were described by Miss Kathleen Kenyon, the field director of the excavation, at a meeting of the Society of Antiquaries of London on May 12. Some years ago excavations were carried out with the object of determining the position and character of the defences of the legionaries' camp, but without success, nor has investigation been more successful on the present occasion. Much information, however, has been obtained about the history of the city. It would appear that Uriconium, which was the fourth largest Roman city in Britain, was founded about A.D. 48 as the headquarters of the Fourteenth and Twentieth Legions, of which it was the station while Wales was being subdued. When the legions were moved to Chester, Uriconium became the tribal capital of the Cornovii. Two successive defensive systems of the city have been found, of which the earlier, dating from about the end of the first century of our era, enclosed a much smaller area than the later. This latter dates from the middle of the second century, and encloses about 170 acres. It marks the largest expansion of the town. The structure known as the Baths Building, which was excavated in 1859, was re-examined. It was found that originally it had not been intended for use as baths, but had consisted of two ranges of large rooms on either side of an enclosed courtyard, with a long two-sided hall beside it. This was built about A.D. 140 and must have formed part of the public buildings, possibly the law courts, of the town. The Forum opposite was nearly contemporary. Not very much later the whole was transformed into an elaborate and complicated bath of the usual Roman type. An interesting discovery was the body of an infant which had been placed below the floor at the time of the alteration, possibly as a foundation burial. At the end of the third century the building was destroyed by fire, but was restored in a partial and slipshod manner. It remained in use for a further hundred years.

Archæological Exploration in the Panjab

ALTHOUGH a considerable period of time has elapsed since the Government of India, soon after the discovery of Mohenjodaro and Harappa, decided to allow duly accredited archæological expeditions from outside India to explore Indian archæological sites, little advantage, unfortunately, has been taken of the opportunity. Two American expeditions and one Belgian have visited India, of which the American expedition to the Salt Hills under Dr. H. de Terra, in a series of investigations extending over several years, has produced much valuable palæontological and archæological material. The excavations at Mohenjodaro for the Archæological Survey were conducted by Dr. E. Mackay, who has since been in charge of further investigations in the Indus valley; but although Dr. Mackay may be regarded as a British excavator, no British expedition has been sent out. This neglect of opportunity is the more to be deplored in view of the evident importance of India for understanding of early cultural development in the Near and Middle East. India itself is now to make an effort to repair this neglect by the inauguration of a "Panjab Exploration Fund", on behalf of which an appeal is issued by Diwan Chaman Lall, president; Prof. E. Dickinson, acting president; and Dr. C. L. Fabri, field director. Funds have been collected in India to begin excavation in the coming autumn on the ancient city site of Surkanwali Ali, near Bhera on the Jhelum, where trial excavations have been made recently by the field director of the Fund. These have revealed the existence of at least five superimposed cities, dating from the Moghul period to pre-Buddhist times. The Fund has the support of the principal scholars and notabilities of the Panjab. A considerable sum is required to place the Fund on a permanent basis; and if a sufficient amount can be raised, it is proposed also to found an ethnographical and archæological museum, for which nucleus collections are already in hand. Contributions should be addressed to the "Panjab Exploration Fund", Imperial Bank, Lahore, or to the London Branch of the Bank, 25 Old Broad Street, London, E.C.2.

Prehistoric Mines in East Africa

EXPLORATION of a cave in the Njoro Forest Reserve of Kenya by Dr. L. S. B. and Mrs. Leakey has brought to light cultural evidence, which they believe, it is stated by the Nairobi correspondent of *The Times* (May 23), points to a connexion with prehistoric opal mining on an extensive scale. The excavations have shown that this cave was used as a place for the disposal of the dead of stone age man. The bodies were brought to the cave, placed in a shallow excavation, and burnt to ashes by a fire lit over them. As time went on, the earlier ashes were disturbed by later incinerations, and the remains of at least sixty bodies have been discovered. The large number of cultural objects found include five hundred stone and one thousand bone beads. The stone beads are especially interesting, as among them are specimens of what appear to be jade and opal, as well as rock crystal and green quartz. Attractive jade pendants were also found. Many of the beads are said to show skilful workmanship, and it is therefore suggested that they may have been brought to East Africa by traders from Egypt and Mesopotamia. The beads are being submitted to experts in England for examination and report. It has been possible to reconstruct from charred fragments both basket work and rope work, and an exquisitely carved wooden vessel. Dr. Leakey, it is stated, attributes the large number of beads found here to trading activities attracted by the opal mines, and, tentatively, suggests 4000 B.C. as a possible date.

Plastics and the Glass Industry

IN his address to the Fifth Glass Convention held last week at Droitwich under the presidency of Mr. H. S. Williams-Thomas, Dr. V. E. Yarsley stressed the view that plastics are not to be regarded as substitutes for the older materials, glass, wood and metals. Much of the work done on the new transparent plastic materials such as the methacrylate and polystyrol products has been inspired by glass. In aircraft construction, where low weight must combine with security and good optical properties over a wide range of temperature conditions, 'organic glass' has no rival. The technique of the manipulation of these materials has progressed very considerably, but, as was brought out in discussion afterwards, not sufficiently to enable a bottle, for example, to be blown from a plastic mass in the manner in which molten glass is manipulated by fully automatic machinery. Much interest was aroused by the reference by Dr. A. Caress to the optical and other properties of materials of the 'Perspex' type, and Drs. W. M. Hampton and J. C. Peddle pointed out the tremendous range of optical properties furnished by the optical glass manufacturers to comply with the requirements of the instrument makers, and the need for both homogeneity and very precise annealing. It appears that as yet the only serious competition that might be feared in this field is in the manufacture of ophthalmic lenses, and mass-produced lenses of the type used in very cheap cameras.

"Frustration of Science" Exhibition

THE Scientists' Section of the Left Book Club held an exhibition on May 17–22 at the Unity Theatre, Goldington Street, N.W.1, illustrating "The Frustration of Science". Charts, pictures and select quotations illustrated the contrast between science as a constructive force in society and science as a weapon of destruction, science as a means towards arousing and satisfying communal needs and science merely as an instrument for profit. Side by side with evidence of the increasing concentration on productivity from the soil was shown the destruction of commodities and foodstuffs. Alongside the figures showing the multiplication of productivity was widespread evidence of malnutrition and scarcity. The meagre sum spent on health research was contrasted with that devoted to investigations in chemical warfare; and the repression of scientific work and the destruction of scientific opportunity in Fascist countries were pointedly illustrated. Comparative graphs showed the speed-up in production that follows from rationalization, and the lag that exists between this and the index of wage rates. In the advertising of fictitious remedies for all kinds of diseases, approximately £3,000,000 per annum is spent, as compared with £139,000 per annum expended from Government sources on medical research in Great Britain. A total retail turn-over of these remedies amounts to £20,000,000 per annum.

The exhibition was opened by Prof. P. M. S. Blackett, who dealt with the historical factors that called science into being, and underlined how these same forces were now frustrating it. In discussing the treatment of scientific men in Fascist countries, he stressed its blindly reactionary character, its penalization of scientific workers in the first instance and, in the drive towards war, how later it had become essential to reverse that policy, in order to regain military and aerial efficiency. It was not, he considered, the task of men of science to solve these problems by their action alone, any more than they had alone called this situation into being; but it was their duty to discard their scientific aloofness and to bring their special knowledge and understanding to bear on these social issues in order to show, in terms of social forces, how the present situation had arisen, and so to discover a way out.

Trans-Atlantic Steam Navigation

IN connexion with the recent commemoration of the centenary of the inauguration in 1838 of trans-Atlantic steam navigation, an article on which appeared in our issue of March 26, p. 540, Mr. J. W. Morgan, of Springfield, Ohio, has directed our attention to the voyage from Nova Scotia to England in 1833 by the Canadian-built steam vessel *Royal William*. The performance of this vessel led the Canadian Government in 1895 to place a commemorative tablet on the walls of the Parliament Buildings in Ottawa, on which she is referred to as "The First Vessel to Cross the Atlantic by Steam Power . . . The Pioneer of Those Mighty Fleets of Ocean Steamers by which Passengers and Merchandise of all Nations are now Conveyed on Every Sea throughout the World". The *Royal William*, of about 800 tons and 200 horse-power, left Pictou on August 17, 1833, and arrived off Cowes, Isle of Wight, nineteen days later. It has sometimes been stated that she crossed under steam power alone, but that statement cannot be substantiated. As Engr.-Capt. Smith was careful to point out in his lecture at the Science Museum on March 16, every steamship both before, and long after 1838, was fitted with sails and made the fullest possible use of the wind. Indeed it is quite impossible to say with certainty what vessel first crossed the Atlantic by steam power alone. The Atlantic had been crossed by the steamers *Rising Star*, *Curaçao* and *Savannah* before the *Royal William* made the passage, but their voyages, like hers, had nothing to do with a considered scheme for a regular service. The true significance of the events of 1838, the year which saw the Atlantic crossed and recrossed by the *Sirius*, *Great Western*, *Royal William II* and *Liverpool*, lies in the fact that they were the first vessels placed on the run with the idea of maintaining regular communication between Great Britain and the United States by steam in all weathers and at all times of the year. Of the four ships, it was the *Great Western* which unmistakably demonstrated the feasibility of the project. She was the true forerunner of our modern Atlantic liners.

Farming in the U.S.S.R.

FARMING in Soviet Russia is the title of a recent interesting article by Sir John Russell (*J. Min. Agric.*, 44, 1063). The natural conditions of this vast territory vary from arctic to sub-tropical, and the agricultural products are in consequence correspondingly wide, ranging from rye, flax and potatoes in the north, through wheat, sunflower and sugar beet in the temperate zones, to oranges and tea in the sub-tropical regions. The preponderance of grain cultivation and the small production of animal products is the chief general feature of Russian agriculture, a characteristic shared by other non-tropical continental regions such as Canada, but the distinguishing mark of the Russian system is that it is planned by a central authority, and the production of certain quantities of the various products are allocated in turn to the constituent republics, regions and collective farms by their appropriate managements. There are two types of farm, namely, the State and the collective farm. The former are managed by State officials, and the employees receive a definite wage in money. The collective farm, on the other hand, is a new departure in agricultural organization. The entire land, live stock and implements are pooled and the whole is worked as a single unit under a committee of management. Workers are allotted certain duties and their achievement is reckoned in terms of 'labour days', a standard day's labour of ploughing or milking, for example, being assessed by the committee. After the Government's claim on the produce has been fulfilled, the remainder is divided between the workers on a basis of their 'labour days', that is, their wages are in kind only. Some 98 per cent of the sown area is now in collective farms, and the peasants appear more contented than previously, so quite apart from political and social issues, the progress of this new system will be closely followed by all interested in agriculture.

Fuels for Heating and Hot-water Supply

MR. H. L. PIRIE, in a paper presented at a joint meeting of the Institute of Fuel and the Institute of Heating and Ventilating Engineers on December 1, discussed the suitability of British coal and its derivatives for heating and hot-water supply. Selection of fuel must be dependent entirely on the purpose in view, available supplies and apparatus. Gas and electricity may be regarded as coal derivatives and present certain advantages over both coal and coke for specific requirements. Nevertheless, fuel and appliances must be considered together if efficient performance is expected. Open fires, continuously burning stoves, hot-water boilers, central heating boilers and steam boilers all require special types of fuel. Mr. I. Lubbock, at the same meeting, assessed the advantages of fuel oil for heating and hot-water supply. Summarily these are: comparatively small space occupied by plant and fuel, rapid and easy filling of storage tanks, which, by suitable piping may serve two or more widely separated boiler houses, cleanliness, lack of smoke, flexibility of supply to meet the needs of varying atmospheric conditions, elimination of standby losses, automatic control, and thermal efficiency. Admittedly, gas and electricity may possess in many cases similar advantages, but they should all be taken into account in fuel selection. Fuel oil is moreover suitable for widely different types of installation. For example, it is now extensively used in office buildings, cinemas and theatres, churches, factories, hotels, trains, garages, flats, and houses, and the types of boiler which it is possible to install in these places are of necessity highly divergent. It is not claimed that fuel oil is better in every case than any other fuel, but it is claimed that oil as a fuel for central heating and hot water should be considered on its own merits in relation to other fuels.

Archæology in the University of London

CHANGES of no little importance for archæological studies are announced in the examination arrangements of the University of London. In and after 1939 no examination for the degree of B.A. in honours in archæology will be held; but archæological subjects will be added as optional or special subjects in the B.A. honours examination in classics, Greek, Latin, Arabic, Chinese, Hebrew, Indo-Aryan, Persian and history. Further, the subject of "Prehistory of Western Europe" is added to the list of subjects which may be taken at the B.A. (General) examination. In view of the very marked progress and development in method of prehistoric studies relating to western Europe in recent years the inclusion of this subject in the general arts curriculum is especially noteworthy, marking an advance in status among academic studies. Similarly at Oxford, by a decree of Congregation, geography and anthropology jointly have been elevated to the dignity of a 'faculty'.

University of London: Progress since 1900

IN his report on the work of the University during the year 1937–38, Dr. H. L. Eason, the recently appointed principal, briefly reviews the progress that it has made since it became a teaching university in 1900 (University of London. Report of the Principal on the Work of the University during the Year 1937–38. Pp. 13. London: University of London). The number of candidates for examination increased sevenfold to 46,000, their fees tenfold to £188,000, the expenditure of the University, exclusive of grants dispensed to schools, institutions and departmental institutes, tenfold to £247,000. There are now in the schools and institutions of the University 240 professors, 160 readers and 945 recognized teachers; the roll of internal students reading for degrees and diplomas comprises 13,730 names, whilst the registered external students number 10,771. Of the 4,863 candidates for degrees in 1937, 3,074 were internal and 1,789 external. The principal recalls words used by Lord Haldane in 1920: "It ought to be the chief centre of learning in the entire Empire, . . . Here ought to be concentrated the highest talent, the highest level in that passion for excellence of which I have spoken, the highest atmosphere, such as only can come in a great capital at the heart of a great country." More and more, says the Principal, does the University approach this ideal. Among the notable events of the past session was the inauguration of a Research Fund to which the University Court resolved to appropriate not more than £5,000 a year, from which grants are to be made for specific projects for research.

Research in Tropical Medicine

The Medical Research Council is offering up to three junior fellowships immediately, for award to qualified medical men wishing to receive training with a view to careers in research work in tropical medicine. The fellowships will be tenable for three years. The first year will be spent at a school of tropical medicine; the second in doing research in the same or some other institution at home; and the third largely in work under direction at some centre in the tropics. The stipend will be at the rates of £300, £400 and £500 per annum in the successive years, with an additional allowance during service abroad and necessary expenses. In three years' time, at least one senior fellowship will be available for candidates who have held the junior fellowships. This will be awarded for a further period of three years, carrying stipend at the rate of £600–£750 per annum, with an additional allowance during service abroad and expenses. The time will be spent mainly in research work in the tropics. The Council is also prepared to consider immediate applications for senior fellowships from candidates who have had adequate experience in research work, whether already specially trained in tropical medicine or not. The Council further intends to establish in due course, as suitable investigators become available as the result of the fellowship scheme, permanent and pensionable appointments for research work in tropical medicine, including senior posts. Further information can be obtained from the Secretary, Tropical Medical Research Committee, 38 Old Queen Street, London, S.W.1.

Rich Display of the Aquarids

Mohammed A. R. Khan, Begumpet, Deccan, carried out observations of the η Aquarids on May 1–5, the total time of observation being $3^h\,45^m$. During this period he saw 37 Aquarids and 32 sporadic meteors. The Aquarids are described as moving with long, white, evanescent trains, and the maximum display took place on May 2. In 1935 the maximum occurred on May 5 and was not so rich as this year. An interesting and important note is added by the observer. In some cases, not only with the Aquarids, but also with the sporadic meteors, the meteors grew considerably brighter towards the end of their course. One Aquarid, starting with a scarcely visible nucleus, developed a long voluminous train, glowing with a beautiful apple-green luminescence, towards the end of its flight. A sporadic meteor which was moving rather slowly developed a bright coma of reddish-green colour, attaining a magnitude 3 at maximum. These facts are important in connexion with a photograph of a meteor shown by Mr. E. H. Collinson at the meeting of the British Astronomical Association on March 30. It was suggested by some members that the bright portion of the photograph was the beginning of the path, but those who were experienced in meteor work did not corroborate this view. The observations from Begumpet confirm the usually accepted fact—that meteors generally brighten up towards the end of their flight.

The Night Sky in June

The summer solstice on June 22 brings the shortest night lasting, in the northern latitude of Greenwich, less than $7\frac{1}{2}$ hours, according to the sun's setting and rising, and a little more than 3 hours if twilight (nautical) be taken into account. The moon is full on June $12^d\,23{\cdot}8^h$ and new on June $27^d\,21{\cdot}2^h$ U.T. A lunar conjunction takes place with Jupiter on June $19^d\,3^h$: with Saturn on June $22^d\,15^h$ and with Venus on June $30^d\,14^h$. Venus, a bright star in the evening western sky, sets at about $22\frac{1}{2}^h$, preceded by Mars. Jupiter rises before 0^h after June 10; its present stellar magnitude is about $-2{\cdot}1$, as compared with $-3{\cdot}4$ for Venus. Saturn is reappearing in the skies as a morning star, and in the middle of the month rises after 1^h. About 21^h in mid-June, Arcturus stands out conspicuously on the southern meridian. Lower in the south at this time will be found Spica just west of the meridian and Antares on the east. Antares, with a radius 450 times that of the sun's, has an average mean density of only 1/3,000 that of air at N.T.P. From a radiant not far from Antares come the slow-moving fireballs known as Scorpiids. Two interesting double stars in Bootes may be noted—ϵ Bootis, having the euphonious name of *Pulcherrima*, is a beautiful double the components of which, separated by $2\frac{1}{2}''$, are a 3rd magnitude yellow star and a blue star of magnitude $6\frac{1}{2}$. ξ Bootis, with a period of about 160 years and an orbit of great eccentricity, comprises a yellow star (mag. 4·7) and a purple star (mag. 6·6) separated by about $4\frac{1}{2}''$. α Herculis provides another finely coloured pair—a mag. 3·0 orange star and a blue green mag. 6·1 also separated by $4\frac{1}{2}''$. Between η and ζ Herculis may be seen a nebulous spot of light which is the well-known globular cluster in Hercules. The stellar population of this spherical system is not less than 50,000 stars; these occupy a volume of space (500 light years across) which would be able to contain the greater number of our naked-eye stars.

Announcements

The degree of doctor *honoris causa* has been conferred by the University of Athens on Sir James Frazer in recognition of his distinguished contributions to Greek classical learning.

Sir Frederick Hobday, formerly principal and dean of the Royal Veterinary College, will give a course of six lectures entitled "A Comparison of Diseases in Animals and Men" at St. George's Hospital Medical School, London, at 5 p.m. on Mondays from May 30. They will be open to medical and veterinary practitioners and students without fee.

The following Royal Society lectures have recently been announced: June 16, Bakerian Lecture by Prof. C. K. Ingold, professor of chemistry in the University of London, on "The Structure of Benzene"; June 30, Croonian Lecture by Prof. A. N.

Richards, professor of pharmacology in the University of Pennsylvania, on "Processes of Urine Formation"; November 10, Ferrier Lecture by Prof. E. D. Adrian, Foulerton research professor, on "Some Problems of Localisation in the Central Nervous System"; December 8, Pilgrim Trust Lecture by Dr. I. Langmuir, associate director of the General Electric Co., New York, on "Molecular Films". All lectures will commence at 4.30 p.m.

AT the anniversary meeting of the Linnean Society held on May 24, the following officers were elected for the year 1938–39: *President*, Dr. J. Ramsbottom; *Treasurer*, Mr. Francis Druce; *Secretaries*, Mr. M. A. C. Hinton (zoology) and Mr. I. H. Burkill (botany); *New Members of Council*, Prof. W. A. F. Balfour-Browne, Mr. R. H. Burne, Dr. G. R. de Beer, Dr. E. Marion Delf, Dr. Anna B. Hastings.

THE following have been elected to fill the vacancies on the board of the Institute of Physics which will occur on September 30: *President*, Dr. C. C. Paterson; *vice-president*, T. Smith; *honorary treasurer*, Major C. E. S. Phillips; *honorary secretary*, Prof. J. A. Crowther; *ordinary members of the board*, Dr. J. D. Cockcroft and E. B. Wedmore.

THE National Fitness Council for England and Wales (1 Queen Anne's Gate Buildings, Dartmouth Street, S.W.1) has set up a Medical Committee with the following terms of reference: (1) To take such action as may be found desirable in order to enlist the co-operation of the medical profession in promoting the policy of the Council; and (ii) To consider and report on the medical aspect of the Council's work. The chairman of the Committee is Lord Dawson of Penn, and the vice-chairman Sir Kaye le Fleming.

THE Minister of Finance of Northern Ireland has announced that the Government proposes to increase the annual grant to Queen's University, Belfast, by £20,000. The University receives at present from this source £40,000 annually for general purposes, and £7,000 for the Faculty of Agriculture. The Government also proposes to make a grant of £2,500 a year to Magee University College, Londonderry, which is affiliated to the University of Dublin, and to increase the annual grant to Armagh Observatory from £100 to £300, and to make to the observatory a special grant of £150 this year.

A LARGE earthquake was recorded at Kew Observatory on May 23. The first movement arrived at Kew at 7h. 31m. 11s. G.M.T. and the record indicates that the shock originated 5,900 miles away in Japan at 4.19 p.m. local time. The largest movements of the ground at Kew were about 1/50 of an inch.

THE tenth International Congress for Psychiatry will be held in Oxford on July 29–August 2 under the presidency of Prof. C. G. Jung of Kussnacht. Further information can be obtained from the secretary, Mr. H. Gibbs-Smith, 106 Brompton Road, London, S.W.3.

THE forty-third Annual Congress of the South-Eastern Union of Scientific Societies will be held at Worthing on June 21–25, under the presidency of Dr. Julian Huxley. The subject of Dr. Huxley's presidential address will be "Natural History—Taxonomy and General Biology". Further information can be obtained from the honorary general secretary, Mr. A. Farquharson, Le Play House, 35 Gordon Square, London, W.C.1.

THE second Conference of the International Guild of Hospital Librarians will be held in Berne on June 7–10, when the speakers will include Mrs. M. E. Roberts, Mrs. Beddington, Mrs. Raymond, Dr. Georges Duhamel of Paris, Prof. Walter Gut and Dr. Wyrsch. Further information can be obtained from the Secretary of the Guild, 48 Queen's Gardens, London, W.2.

AN institute for the study and prevention of occupational diseases has recently been established in Paris by the French Minister of Health. The institute, which is the first of its kind in France, includes an examination room, a laboratory for extensive chemical and toxicological research, a special photographic laboratory and a library of international literature dealing with occupational diseases. The organ of the institute is the *Archives des maladies professionnelles, d'hygiène et de toxicologie industrielles*, which will appear every two months. Further information can be obtained from the Secretary, Institut d'étude et de prévention des maladies professionnelles, 6 rue de la Douane, Paris X^e.

Under the joint auspices of the Institution of Naval Architects and of the Institute of Marine Engineers an International Conference of Naval Architects and Marine Engineers will be held in London on June 16–18. It is anticipated that some three hundred, including ladies, will attend from many parts of the world in addition to the British participation. Important delegations are expected from Belgium, France, Germany, Holland, Italy and the United States of America. Further information and a programme of papers can be obtained from the Secretary, Mr. C. V. Boys, 3 Robert Street, Adelphi, London, W.C.2

A SIXTH spectroscopy conference will be held at the George Eastman Research Laboratories of the Massachusetts Institute of Technology on July 18–20, repeating the type of programme presented at the conferences held during the past five summers. Morning and afternoon meetings will be held on three days. Papers and discussions on analysis of materials by the emission spectrum, absorption spectrophotometry, photographic photometry, biological and chemical effects of spectral radiation, and industrial applications of spectroscopy, are being prepared. The usual summer courses on practical and applied spectroscopy will be offered at the Institute between June 13 and July 23. Further information can be obtained from Prof. George R. Harrison, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts.

Letters to the Editor

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 978.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Nitrogen and Argon in the Earth's Crust

IN a recent letter[1], it was stated that various specimens of granite contain per gram about 10^{-6} c.c. of neon and 4×10^{-5} c.c. of argon. This makes the ratio neon/argon some thirteen times as great as in the atmosphere.

The same rocks and a considerable number of others have now been examined for nitrogen. The quantity found is remarkably uniform, and amounts to about 3×10^{-2} c.c. per gram. Various evidence indicates that the nitrogen is not occluded like the argon and neon, but is for the most part held in chemical combination.

The ratio argon/nitrogen comes out about $1{\cdot}3 \times 10^{-3}$. The atmospheric ratio is about $1{\cdot}2 \times 10^{-2}$, some nine times greater.

It appears from these nitrogen determinations that, contrary to what has been supposed, the total nitrogen in the earth is many times more than in the atmosphere. It has been estimated[2] that 0·65 of the earth's mass consists of rock. On this basis, it may be calculated that the rocks contain thirty-seven times as much nitrogen as the atmosphere.

Discussion of the cosmological bearing of these results is deferred.

Absorption Bands and Electron Transitions in Coloured Fluorites

THE absorption spectra of fluorites coloured by natural or artificial irradiation show, in general, principally two regions of strong absorption[1]: from 350 to 470 mμ and from 530 to 650 mμ. The latter has already been attributed to reduced calcium, either as isolated atoms or as colloidal particles; the former can now be attributed to the bivalent ions of the rare earth elements, which, as has been shown before[2], are responsible for the diffuse fluorescence bands of fluorites. The blue Eu++-band has its maximum of excitation[3] in the region of 350–390 mμ, the red band of Sm++ in CaF_2 most likely towards 430 mμ. The red Sm++-fluorescence of some natural fluorites is connected with absorption maxima between 420 and 470 mμ. The different colours of fluorites can now be explained by the varying intensities of the different absorption maxima: Eu++ alone gives a light yellow colour (for example, Derbyshire), Sm++ a deeper yellow brown (Wölsendorf and others), the bivalent rare earths together with the Ca-maxima give the green colours (Weardale), predominance of the Ca-maxima the blue and violet colours, violet corresponding to a more disturbed lattice (larger colloidal particles ?).

Various colour changes through heat or light can be attributed to the transfer of electrons from the bivalent rare earth ions to the calcium ions and back, for example, the 'improving' of the colour of greenish fluorites by exposure to sunlight[4], which gives deeper purple colours: reduction of calcium by electrons given off photo-electrically by the bivalent rare earths. In some yellow and green fluorites, this transfer is reversible at low temperatures[5]: irradiation with ultraviolet light in the rare earth maximum diminishes this and builds up the calcium maximum (violet colour); irradiation in this maximum by yellow light reproduces the original colour. This return is accompanied by luminescence and one can, in this case, regard the 'excited' state of fluorite as due to the transfer of electrons from the bivalent rare earths to the calcium, that is, to a chemically different constituent.

Another example of this electron transfer is perhaps given by certain fluorites that fluoresce red (Sm++) in their natural state. This red fluorescence is sometimes increased by heating the sample[6], the electrons returning from the Ca-atoms to the Sm+++-ions and reducing them to Sm++, an effect that can also be obtained by artificial radium treatment.

If circumstances allow, a more detailed account will be given elsewhere.

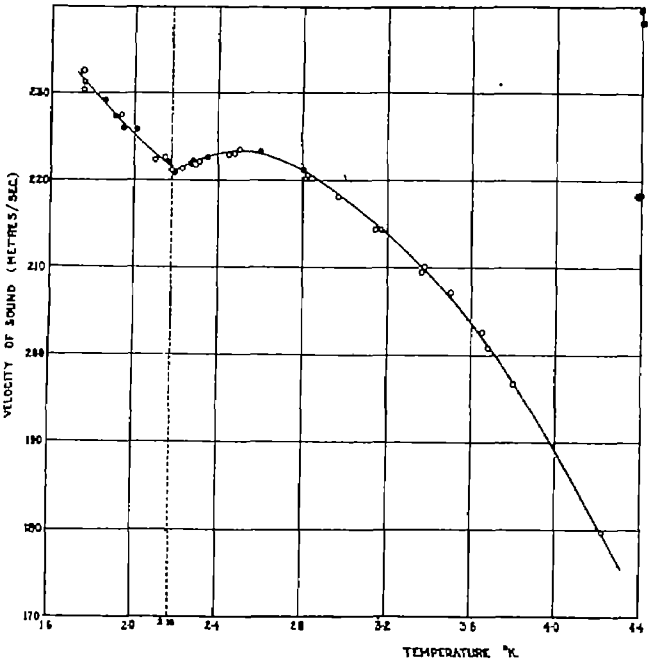
Velocity of Sound in Liquid Helium

THE velocity of sound in helium I and helium II has been determined by a method similar to that used by Pitt and Jackson[1]. Standing waves were set up in the liquid between a vibrating quartz crystal and a brass reflecting plate. The crystal was driven near its natural resonance, at a frequency of 1,338 kilocycles per second, maintained constant by means of a quartz crystal master oscillator. The reflector was moved by means of a micrometer screw, and as it passed through the nodal positions, the existence of the standing waves was shown by the resonant reaction on the vibrating crystal. Sharp and easily measurable resonance peaks were obtained in both helium I and helium II, the wave-length being of the order of 0·16 mm. The temperature was controlled by means of the helium vapour pressure.

The accompanying graph shows the results, velocity in metres per second plotted against temperature in °K. The points marked by solid circles are considered less reliable than the open circles. For the remainder, the probable error is estimated to vary from about 0·1 per cent in helium I to about 0·25 per cent at the lower temperatures in helium II.



CURVE SHOWING RELATION BETWEEN TEMPERATURE OF LIQUID HELIUM AND THE VELOCITY OF SOUND IN IT.

The velocity at points not too close to the λ-point agrees approximately with the values calculated from the adiabatic elasticities estimated with the aid of the entropy relations[1]. It is doubtful whether the expected discontinuity in velocity at the λ-point occurs or not, and it is certainly less than 0·5 per cent. The change in elasticity calculated from Ehrenfest's relations for a phase change of the second order[3] would cause a decrease in the velocity from helium I to helium II of about 2·5 per cent. Other than this disagreement, there is no reason to suppose that the ordinary formula for the velocity of sound is not obeyed in both helium I and helium II, and it is hoped that the results may be used to adjust the entropy relations for liquid helium.

Profs. Grayson Smith, J. O. Wilhelm, A. Pitt and Mr. J. C. Findlay have co-operated in this work.

Absorption of Group *A* Neutrons in Silver

IN examining the details of the silver resonance level for Group *A* neutrons, it becomes important to know the self-absorption coefficient for very thin absorbers and detectors. This information is, for example, useful in the interpretation of experiments on the Doppler broadening of this level[1].

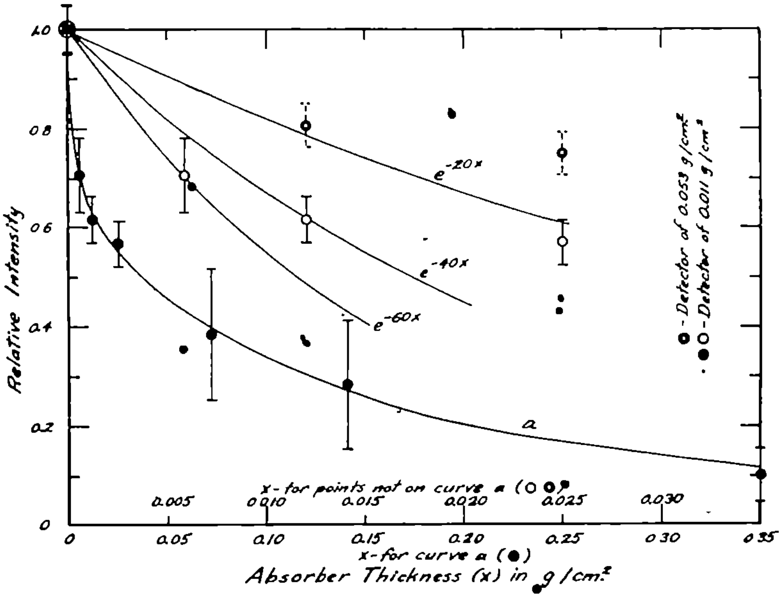
In their early survey of slow neutron effects, Amaldi and Fermi[2] found, with a detector of 0·057 gm./cm.^{2}, an average absorption coefficient of 20 cm.^{2}/gm. for group *A* neutrons in silver. Since the influence of self-reversal[3,4] should be important for a detector of this thickness, it was thought worth while to determine again the self-absorption curve for these neutrons with a thinner detector (0·011 gm./cm.^{2}), and with reasonably good geometry.

A hinged support allowed six silver foils (15 mm. diameter) to be activated simultaneously, and permitted their activities to be followed at one time with a single thin-walled Geiger-Muller counter. Collimating channels, in the equivalent of 0·7 gm./cm.^{2} of boron lined with 0·35 gm./cm.^{2} of silver, led to each detector, restricting the inclination of activating neutrons to 30° or less. Frisch[4] showed that in permitting such an angle of approach one would introduce an error independent of absorber thickness which would give activities corresponding to absorbers 7 per cent thicker than actually used.

The source of slow neutrons was 300–800 mc. of radon plus beryllium imbedded in paraffin. A cadmium filter of 0·83 gm./cm.^{2} was used to eliminate thermal neutrons. Scattering materials in the neighbourhood of the detectors were carefully avoided. The detectors were irradiated for 45 seconds, and measurements of one minute duration were begun 15 seconds later. All results were corrected for the presence of the 2·3 minute period and for the contribution of Group *B* neutrons.

The accompanying figure [see over] shows the final absorption curve for detectors of 0·0114 gm./cm.^{2} (Curve *a*), and, on a thickness scale ten times larger, the initial part of the same curve and corresponding points for detectors of 0·053 gm./cm.^{2}.

The absorption coefficient (20 cm.^{2}/gm.) for the thicker detectors agrees with the value of Amaldi and Fermi[2]. The points for zero and 0·0058 gm./cm.^{2} absorption, with thin detectors, give, however, an absorption coefficient of 59 ± 19 cm.^{2}/gm. This value represents a minimum, because even for the thin detector, self-reversal would be expected to make the absorption coefficient lower (possibly 25 per cent) than the true initial absorption coefficient. Also, the rather uncertain correction for the influence of Group *B* neutrons was made in such a way as to give the absorption coefficient too low a value. A minimum value for the contribution of this group was estimated by correcting to the amount of Group *A* to be expected with the thickest absorber used assuming resonance form for the line (Doppler broadening was neglected, making the value for the Group *A* component a maximum). As the self-absorption coefficient for Group *B* is unknown, the same correction was taken for all absorber thicknesses. The boron-silver shield for Group *A* was comparatively transparent for the less absorbable group; so the Group *B* correction was 50 per cent



as large as the initial intensity attributed to Group *A*. It is estimated that the error introduced by this correction would tend to make the apparent initial absorption coefficient 10–15 per cent too low.

Considering that only one of the two equally abundant silver isotopes should be effective in the resonance absorption of Group *A* neutrons, the absorption coefficient indicated above should be doubled, giving 120 cm.²/gm. This value, which represents by far the largest resonance cross-section measured to this time, cannot be used with activation values of Amaldi and Fermi[2,5,6] to determine the total width of the line because it leads to the following contradiction: the combined natural and Doppler width so determined is smaller than the Doppler width alone obtained directly from the energy of the line and the mass of the silver atom.

A discussion of this measurement as related to the Doppler effect[1] will appear in the *Journal de Physique*.

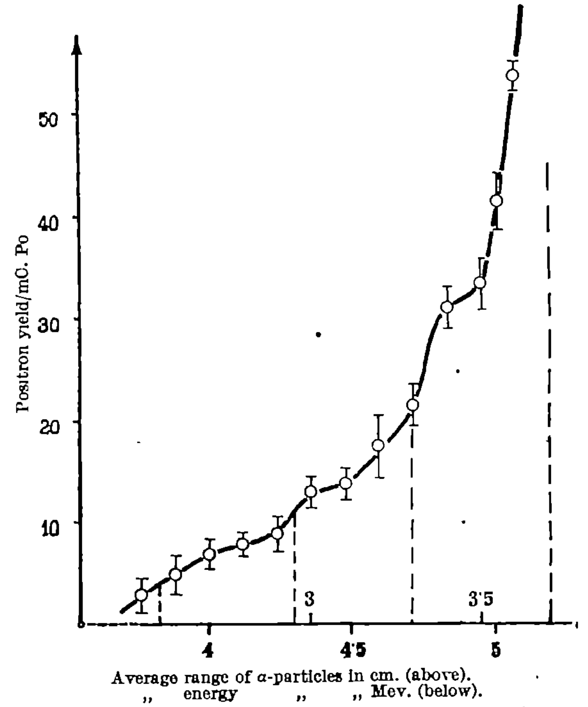
Fine Structure of the Yield-Curve of the Transmutation of Aluminium

THE yield-curve of the transmutation ^{27}Al (α ; ^{1}n)^{30}P is of theoretical importance in relation to that of the transmutation ^{27}Al(α ; ^{1}H)^{30}Si. Four very definite resonance levels have been observed for the proton emission[1,2] with α-particles of ranges 2·5–4·0 cm. In spite of this, one very broad, or some less definite levels have been observed for the neutron emission[3,4]; the yield-curves of the two transmutations seemed to be different.

Since the yield of the neutron emission is much smaller than the proton yield at these ranges, a larger solid angle of the α-particle beam was favoured by recent investigators on account of the uniformity of the ranges. It would be essential to bombard with α-particles of uniform range to resolve the levels.

In the present work, a target consisting of an aluminium hemisphere of 50 mm. diameter was bombarded from a polonium source of 3 mm. diameter at its centre[5] (strength about 10 mC.). This arrangement enabled us to obtain a solid angle of 2π, and the inhomogeneity due to different paths of the α-particles was not more than 1 mm., when retarded by a carbon dioxide atmosphere of 10 mm. air equivalent. An inhomogeneity of ± 1 mm. arose in a gold layer of 1 mm. air equivalent, covering the surface of the source. The large solid angle of the activation enabled us to obtain a reasonable yield although the source was weak. The target was activated to saturation of ^{30}P and was put over a counter which consisted of a hemisphere of aluminium (about 50 mgm./cm.²). The counter had a loop (platinum wire) of 3 mm. diameter in the centre and was filled with argon and alcohol vapour[4].

The graph below shows the integral yield (thick target) of positrons from ^{30}P per mC. polonium for infinite exposure as a function of the average ranges of the α-particles. At each α-range where levels have been observed for the proton emission



THE YIELD-CURVE OF THE TRANSFORMATION ^{27}AL (α; ^{1}n)^{30}P. NUMBER OF POSITRONS FROM ^{30}P PER MC. POLONIUM (THICK TARGET, INFINITE EXPOSURE) AS A FUNCTION OF THE ENERGY OF THE EXCITING α-PARTICLES. DOTTED VERTICAL LINES DENOTE RESONANCE LEVELS FOR THE PROTON EMISSION.

(dotted vertical lines at 2·55 cm., 2·95 cm., 3·3 cm. and 3·75 cm. average ranges), resonance levels exist for the neutron emission. The first process, the capture of the α-particle, is independent of the emitted particle (proton or neutron). There is a difference in the yield of the levels. All four levels give about the same yield for the proton emission ($3 \cdot 5 \times 10^{-7}$)[1]. A tentative determination of the yield of the neutron emission gives the following values, supposing that about 30 per cent of the positrons entered the counter :

Average range	^1n yield	$\frac{^1H \text{ yield}}{^1n \text{ yield}}$
2 55	$0\ 5 \times 10^{-8}$	70
2 95	$0\ 5 \times 10^{-8}$	70
3 3	$1\ 5 \times 10^{-8}$	23
3 75	$3\ 5 \times 10^{-8}$	10

It is interesting that the branching ratio, proton yield/neutron yield, decreases with increasing energy of the exciting α-particle. Differences in the change of energy at the two transformations give a very obvious explanation for this fact.

The apparatus has been built in the Institute of Physics, Debrecen, Hungary, by means of a financial grant from the Academy of Sciences, Budapest. I wish to thank Prof. Z. Gyulai for his kind interest, and also Prof. St. Meyer and Prof. G. Stetter for their valuable suggestions and for having allowed me to carry out the measurements in Vienna.

Measurement of the Anærobic Glycolysis of the Regions of the Amphibian Gastrula by the Cartesian Diver Ultramicromanometer

THE use of the Cartesian diver as an extremely sensitive micromanometer was suggested in this journal last July by Linderstrøm-Lang[1], and the description of the technique was somewhat amplified in a subsequent note[2]. Since adequate micromethods are, for the embryologist, indispensable, we have employed ourselves since that time in the adaptation of the method for use with small pieces of tissue, and in particular with the regions of the amphibian gastrula dissected out by the Spemann glass needle technique.

The delicacy of the method in its present form may be gauged by the fact that whereas 1 cm. on the scale of the usual Warburg manometer corresponds to a gas change of about 20 c.mm., 1 cm. on the scale of the diver manometer corresponds to a gas change of 0·008 c.mm.

For our purpose, a number of special problems required solution. (1) Fragile embryonic tissue cannot be passed through an air-water interface, and the divers must therefore be submerged beside the tissue fragments in the medium to be used. In our experiments the medium used was Holtfreter solution containing an amount of bicarbonate sufficient to bring it into equilibrium with 5 per cent carbon dioxide in nitrogen. After the fragments have been pushed into the diver bulbs, a known amount of Holtfreter-bicarbonate solution is withdrawn from the divers. (2) Completely anærobic conditions within the divers are attained by handling them inside a special glass chamber with one or more pipettes mounted on glass universal joints. A stream of the nitrogen–carbon dioxide mixture passes through the chamber and the pipette. (3) As pieces of tissue of the order of 100 γ dry weight are used, a new Kjeldahl technique was devised for measuring the amount of total nitrogen present. The incineration vessels are so shaped that they may afterwards function as diffusion vessels analogous to those of the well-known Conway method. (4) Since total nitrogen was estimated, the ammonium sulphate proposed by Linderstrøm-Lang as the flotation fluid for the divers was replaced by lithium chloride at the same density, which has the further advantage of considerably lower gas solubility. (5) Since developing amphibian embryo tissue, unlike that of adult mammals, forms considerable quantities of ammonia, estimations of ammonia produced during the experimental period were necessary ; these were done following the method of Linderstrøm-Lang and Holter[3]. (6) The method of calibration of the divers was further investigated. A suitably modified Warburg equation was verified for divers of various volumes by direct comparison with Warburg manometers of the usual pattern, using reactions such as the decomposition of oxaloacetic acid and the autoxidation of cystein*. All these adaptations and special procedures will be fully described in forthcoming publications.

The importance of an understanding of the metabolism of the gastrula lies in the fact that the vertebrate axiation of normal development depends on the liberation of a chemical substance or substances at the dorsal lip of the blastopore and not elsewhere. It is known that glycogen disappears from the invaginating material[4], and there is evidence that glycogen may form part of the inactive organizer complex[5]. We now found, by an extensive set of measurements on the embryos of *Rana temporaria*, a substantial difference between the metabolism of the dorsal lip of the blastopore and that of the ventral ectoderm.

	$Q_L^{N_2}$	Ammonia (c.mm./γ dry weight/5 hr.)
Dorsal lip of blastopore	0·63	2·31
Ventral ectoderm	0·21	0·97

While noting the significance of these differences, we would prefer to postpone the discussion of them until data can be obtained for Q_{O_2}, $Q_L^{O_2}$ and *R.Q.*, in the investigation of which we are now engaged.

* We find that although the oil seal greatly retards, it does not completely prevent, the escape of gas from the diver, but if the oil and the lithium chloride solution are previously saturated with the gas mixture, the error due to gas loss is reduced to negligible proportions.

Ascorbigen in Plant and Animal Tissues

WE have previously given evidence[1,2] to show that cabbage contains ascorbic acid in a combined form from which ascorbic acid is released on heating. Chloroform extracts of dried cabbage, which were quite free from ascorbic acid as shown by the indophenol indicator, developed a marked dye-reducing value on heating. Treatment of cabbage with hydrogen sulphide in the hot and cold conditions also led to the same conclusion. Further, it was found by treatment with ascorbic acid oxidase, that 60–70 per cent of the indophenol reducing value of the chloroform extract of cabbage is to be attributed to combined ascorbic acid[3]. This work showed incidentally that, apart from combined ascorbic acid, which we called 'ascorbigen'[4], cabbage contains some non-specific reducing substance also in a combined form.

Biological experiments with guinea pigs confirmed the view that 60–70 per cent of the indophenol-reducing value of the dried chloroform extract of cabbage was due to ascorbigen. The guinea pigs were fed on a scorbutic diet and when they were falling in weight one group was given supplements of ascorbigen and the other group was fed with equivalent doses of ascorbic acid (varying from 2 mgm. to 4 mgm. in terms of ascorbic acid). The rates of growth in the two groups during the next ten days were comparable. Similar results have just been reported by Reedman and McHenry[5], who have given biological evidence for the presence of ascorbigen in potato. They have, however, fed the experimental guinea pigs with ascorbigen and ascorbic acid from the start of the experiment; but their results and ours are substantially in agreement. It has been possible to purify the ascorbigen of cabbage very considerably by extracting dried cabbage with chloroform, treating the dried chloroform extract with water, re-extracting with chloroform, again extracting with water and precipitating with alcohol. The substance is under further investigation.

We have observed the presence of ascorbigen and of some non-specific reducing substance in a combined form in the brain and liver tissues of the normally fed guinea pig. Similar results have also been obtained with urine by Mr. S. Bannerjee in this laboratory, which are confirmatory of the findings of Scarborough and Stewart[6]. It thus appears that the distribution of ascorbigen and some non-specific reducing substance in a combined form in plant and animal tissues is fairly general, though perhaps not universal.

In any estimation of ascorbic acid from the nutritional point of view, the foodstuff should be evaluated with reference to (1) free ascorbic acid, (2) dehydroascorbic acid, and (3) ascorbigen, as we pointed out elsewhere[7]. For this, a method has been developed involving treatment of the material with hydrogen sulphide in the hot condition, removing hydrogen sulphide in a current of carbon dioxide and treatment of an aliquot with ascorbic acid oxidase. This method appears to give the 'total' ascorbic acid of foodstuffs.

Details are being published in the *Journal of the Indian Chemical Society*.

Action of Anol and its Derivatives on the Nipple of the Guinea Pig

Dodds and Lawson[1] have stated that anol will induce œstrus in rats. W. Jadassohn, Uehlinger and Margot[2] have investigated whether anol will cause enlargement of the nipples of guinea pigs by simple external application of the solution of this substance (nipple test with anol). The result was positive although not so strong as with œstrone. Later, Dodds and Lawson[3] found that pure anol in not very large doses failed to induce œstrus. We reinvestigated the action of pure anol in the nipple test and found it to be completely negative. (A solution of the same anol prepared a few months later showed a positive nipple test.)

We have examined by means of the nipple test substances which may have been responsible for the activity of the 'active anol solutions', that is, derivatives of them.

The demethylation of anethol, by means of a Grignard reaction (Serini and Steinruck[4]) gave rise to an anol that contained polymerization products; this polymerized material after acetylation boiled at 180–210° under 0·5 mm. pressure. Similar experiments were also made with isoanol[5] and its acetyl derivatives prepared by heating isoanethol with potassium hydroxide in a sealed tube under pressure (N. R. Campbell, E. C. Dodds and W. Lawson[5]).

All these preparations were active in the nipple test. However, the application of œstrone solution in a concentration of 0·003 γ per c.c. gives a definite effect, whereas these preparations in a concentration of 1 γ per c.c. were quite inactive; 10 γ per c.c. was weakly active and 60 γ per c.c. showed a strong effect.

So far as the nipple test is concerned, we must refer to our previous publications[2,6,7,8]. For the present, however, we shall briefly recall its principle. We have developed a simple method of measuring the enlargement of the nipple (male guinea pig). We have found that external application of very small doses of female sex hormones produces such an enlargement. This method has proved to be specific and quantitative.

'Climbing Organs' in Insects

MANY insects possess adhesive organs (pulvilli, tarsal or tibial pads, etc.) which enable them to climb on perfectly clean glass. Presumably these organs function whenever the foot comes in contact with any surface, such as leaves or polished stones or the bodies of other insects, too smooth for the claws to grip. Miller has suggested[1] that the 'fossula spongiosa' of adult Reduviids may have been developed for the purpose of holding the bodies of their prey; Gillett and I[2] suggested that it might be of use in holding the other sex during copulation.

In unpublished observations on the bed-bug *Cimex*, we could obtain no evidence that the similarly placed organ will assist this insect in walking on glass; the 'fossula' appeared equally unsuited to this purpose in dried specimens of various Reduviids. It is only moderately efficient for this purpose in *Triatoma*[1]; but as anyone can satisfy himself in a few minutes, the adult *Rhodnius* is able to hold and climb on clean glass, even when nearly vertical, by means of this tibial organ. For that reason, it was described as a 'climbing organ'[2]. But since this type of 'climbing' is only a special case of adhesion, and since the natural purpose of such organs is not always clear, it might be preferable to refer to them simply as 'adhesive organs' without prejudice to the question of their normal function. Though very different in appearance from the homologous 'fossula spongiosa' of some other Reduviids, this highly efficient adhesive organ of *Rhodnius* is certainly not a vestigial structure.

Viscosity of Monomolecular Films

Two letters by Harkins and Myers, and by Harkins and Kirkwood respectively, concerning a surface viscosimeter have recently appeared in NATURE[1]. We wish to direct attention to the previous results that we have obtained with a viscosimeter of the same type[2].

We have shown experimentally that the surface flow per second, Q, is in fact proportional to the difference of pressure and inversely proportional to the length of the channel, but we think it necessary to insist that there is no law analogous to Poiseuille's law concerning the width of the slit. The corresponding Poiseuille equation for a two-dimensional fluid should contain a factor d^3 (d = width of slit). The results of our systematic study with channels of different widths show clearly that the problem is much more complicated. There is no doubt that we have simultaneous entrainment of the water and that the viscosity of the substrate becomes the preponderant factor as soon as channel widths of the order of 1 cm. are reached, that is, the flows per unit time become independent of the nature of the fluid film as the diameter increases, finally reaching the same value. The relation with d^3 would be valid only as a limiting law for very narrow channels, since, as the diameter decreases, we find *linear* variation up to 5 mm., this variation gradually changing to d^3 at 0·5 mm.

We think that, even with corrective terms, one can hope to attain only the order of magnitude of the two-dimensional viscosity of the film. The calculation made by Kirkwood is valid only for a deep channel, which is not the case for the viscosimeters used by us and by Harkins. The theory introduced by Bresler and Talmud[3] would give results in better qualitative accord even for large channels, although it introduces arbitrarily a frictional term proportional to the speed in the differential equation. Unfortunately, an error in the integration prevented these authors from observing the accordance cited above.

The correct integrated form should be:

$$Q = \frac{2\varphi}{SA\varkappa}\left[R - \sqrt{\frac{\eta}{A\varkappa}}\tanh\sqrt{\frac{A\varkappa}{\eta}}\,R\right],$$

where φ is pressure gradient; S is surface per gram; A is a constant; $\varkappa$ is the viscosity of water; $R = d/2$; η is viscosity of the film. This gives for large channels the approximate expression:

$$Q = \frac{2\varphi R}{SA\varkappa},$$

and for infinitely small channels

$$Q = \frac{2\varphi R^3}{3S\eta}.$$

Nevertheless, in spite of this theoretical difficulty, one can, by using the experimental values of the flow for a given channel, detect very accurately changes of state in monolayers. We have shown[4], for example, that a liquid film of triolein exhibits at about 115 A.[2] a sharp change in the variation of the viscosity. In the same manner, a fluid film of stearic acid on 0·001 N hydrochloric acid gives changes at about 20·5 and 22 A.[2]. Thus, from this point of view alone, the measurements of surface viscosity constitute already a very promising new method of investigation.

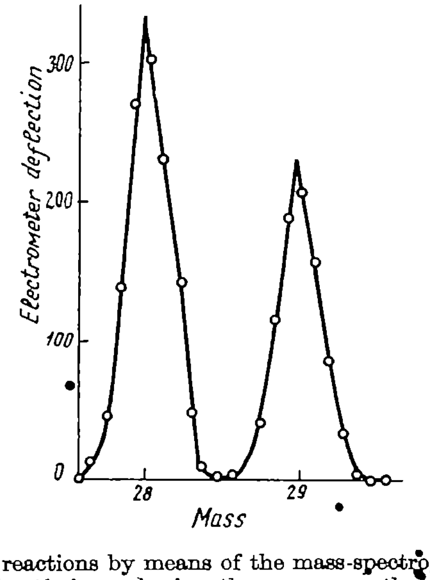
Direct Evidence for the N_2H^+ Ion in the Discharge Reaction between N_2 and H_2

So far as I am aware, no attempt has been made to study chemical reactions and in particular discharge reactions by means of the mass-spectrograph. Thus Lunt[1], in reviewing the numerous theories of discharge reactions including ion clusters, excited or



metastable molecules, kinetic ions, etc., considers that there are no direct grounds for assuming the existence of compound ion formation except in the case of H_3+.

Using a mass-spectrograph of the Dempster type. it has been found that N_2H+ is produced abundantly when a mixture of N_2 and H_2 is bombarded with electrons. The accompanying graph shows the type of curve obtained in $N_2 + 5H_2$ at a total pressure of about 8×10^{-3} mm. From the intensity-pressure curve it appears that N_2H+ owes its origin to N_2+ and not to H_2+, and from the ionization function curve, that the reaction starts at the ionization potential of N_2.

Since compound ions of higher and lower mass were found in only very small quantities, it may be concluded that the formation of N_2H+ is only the first stage in the production of NH_3. The second stage presumably takes place at the walls in the presence of atomic hydrogen, in agreement with the results of Mochan and Gelbert[2].

The probability of the formation of N_2H+ is even higher than that of H_3+. Thus the ratio N_2H+/N_2+ is 4·3 times the ratio H_3+/H_2+ in that part of the pressure range which is free from selective absorption effects.

Connexion between Electromagnetic and Neutrino Fields

As previously stated, one arrives at the formulation of specific 'coherence' (parallel motion) of two neutrino particles forming a photon, if both neutrino mass μ and neutrino 'charge' ε (non-electromagnetic) are put equal to zero but their relation to one another is kept constant[1], $\left(\frac{\varepsilon}{\mu} = \pi\sqrt{\frac{2c^3}{h}}\right)$.

Developing the consequent neutrino theory of light, one must now establish the expressions connecting all components of the electro-magnetic field $\Phi_{\mu\mu'}$ with neutrino wave functions ψ.

All requirements (that is, Maxwell's equations and the commutation rules) are fulfilled if one defines the antisymmetric field tensor by the following equation :

$$\Phi_{\mu\mu'} = i\varepsilon\left(S_v \frac{\partial}{\partial x_v}\right)^2 \Box^{-1}\varphi + \alpha_\mu \varsigma_2 \alpha_{\mu'}\varphi,$$

where $S_v \frac{\partial\varphi}{\partial x_v} = \psi$; α_μ, ς_2 are Dirac matrices and (S_μ) is an auxiliary constant vector, the direction of which corresponds to the definite choice of gauge for electromagnetic potentials[2].

From the neutrino wave function we can further construct two scalars defined by the formula :

$$\Phi = \varepsilon\, S_v \frac{\partial}{\partial x_v}\, \Box^{-1}\varphi + S_\mu \beta_\mu \varphi,$$

where (1) $\beta_\mu = \alpha_\mu$ and (2) $\beta_\mu = \varsigma_1 \alpha_\mu$.

These latter quantities are connected with the longitudinal component of the electromagnetic field.

The above relations yield Coulomb's law for the static case, if the distance between interacting electrons is less than $h/\mu c$, so that Maxwell's electrodynamics is limited from this point of view on the side of very great wave-lengths, which magnitudes depend from the mass of neutrino.

A. SOKOLOW.

Siberian Physical-Technical Institute,

---

[1] Sokolow, A., NATURE, **140**, 810 (1937).

[2] Sokolow, A., "On the Neutrino Theory of Light (3)", *Phys. Z. Sowjetunion*, in the press.

IN Jordan's form of the neutrino theory of light[1], the emission of a photon appears as the absorption and re-emission of a neutrino, or the simultaneous emission of a neutrino and an antineutrino, with identical directions. If the energy E and the momentum $\mathbf{p}$ transferred in the process are related by the equation

$$E = c|\mathbf{p}|,$$

as required by the usual theory, the mass of the neutrino must be assumed zero.

The angular momentum of a photon, in the direction of propagation, is either $\hbar$ or $-\hbar$. Assuming the neutrino to have spin $\frac{1}{2}\hbar$, this implies that the neutrino reverses its spin in the first kind of process, and that in the second kind the two particles have parallel spins.

From the mathematical point of view, the aim of the theory is to express the photon amplitudes, satisfying the commutation relations of the Bose-Einstein statistics, in terms of the neutrino amplitudes, satisfying the commutation relations of the Fermi-Dirac statistics, in a manner consistent with these physical assumptions. This can be shown to be impossible. The impossibility arises from the contradictory requirements of the conservation of angular momentum and the commutation relations. Certain pairs of two-rowed matrices occur, which by the first condition are required to be of the form

$$\begin{pmatrix} 0 & a \\ b & 0 \end{pmatrix}, \begin{pmatrix} 0 & -ia \\ ib & 0 \end{pmatrix};$$

the second condition requires that a and b should be different from zero and that the matrices should commute with one another, and this is easily seen to be impossible. No special form for the Hamiltonian function of the neutrinos need be assumed. A more detailed account has just appeared in the *Proceedings of the Royal Society of London*[2].

The three-dimensional neutrino theory proposed by Kronig[3], which at first seemed to offer a complete solution of the problem, is seen, on closer inspection, not to be invariant against changes of co-ordinates. It also violates the conservation law for angular momentum.

This result does not apply to the theory of Sokolow (cf. previous letter). The main difference between the theories of Sokolow and Jordan is in the mass of the neutrino. In the former it is essential that the rest-mass, however small, should be finite, whereas in the latter it is zero. It seems, if the neutrino theory is to be retained, that some deviation from Jordan's hypothesis, such as Sokolow's, must be tried.

Science, Logic and Philosophy

My attention has been directed by Mr. John Bradley of Christ's Hospital, Horsham, to a passage by Prof. J. H. Muirhead[1], containing the words: "The truth is that what is called a natural law is itself not so much a statement of fact as of a standard or type to which facts have been found more or less to approximate. This is true even in inorganic nature." My statement[2] that the variation of observations from a mathematical formula is quite unknown to philosophical critics has therefore at least one exception, which I am glad to acknowledge. But much in philosophical works would receive additional force from its recognition; for example, in the later parts of Prof. L. S. Stebbing's "Philosophy and the Physicists". Mr. Bradley directs attention also to a passage in Plato: "I have never been able to find out anything for certain and have had to be content with the probable." Locke said the same thing at greater length, and W. E. Johnson made important constructive contributions to the quantitative theory; so I did not intend to disparage the contributions of philosophers to this side of the question.

My opening passage should have been expressed somewhat differently, and should be read in conjunction with the closing one. Two correspondents have referred to it as a refutation of idealism, but it is only a refutation of a particular form of it. I show in the course of the article that the scientific use of generalization can permit even an idealist to escape from solipsism, and my final conclusion is that there are forms of realism and idealism that are scientifically equally valid. My own preference is for the realist one, but I admit that that is pure prejudice. On the other hand, I am not sufficiently familiar with idealist literature to say whether any actual idealist would accept the form of idealism that I consider tenable.

A Binocular Illusion

The interesting binocular illusion described by Prof. Dixon[1] is usually called the wall-paper experiment in England and *Tapetenbilder* in Germany. It has frequently been rediscovered—often by children—and I know of a number of people who have found it out for themselves.

Exactly two hundred years ago Robert Smith[2], afterwards Master of Trinity College, Cambridge, described the illusion of binocularly fusing two candle flames by converging the visual axes on a nearer point. The effect was that of a smaller candle closer to the observer. H. Meyer[3] in 1842 published a detailed account of the phenomenon as seen in patterned wall-papers. Two years later it was seen by D. Brewster[4] in wall-papers, carpets, and other patterned objects. He described the curious unreality of the appearance—a semi-transparent object suspended in the air and moving with every movement of the observer. He always claimed to be the original discoverer, and made no reference to Smith or Meyer.

The chief physiological interest of the illusion is that it has seemed to several writers to indicate that the amount of convergence of the eyes necessary to avoid diplopia is an important datum in the visual judgment of distance. It is possible, however, that the illusory closeness of the percept is mainly due to the fused pattern being judged to be at about the known distance from the observer of the fixation point, or of other objects the images of which fall on corresponding points of the two retinas.

Ounce Molecular Weight of a Gas

The useful equivalence, gm. per litre = oz. per cub. ft. (approx.), as a practical connecting link between metric and British weight-volume relationships, referred to by Dr. H. D. H. Drane in Nature of April 30 (p. 791) is well known to industrial chemists and engineers, and appears in Woodward's "Logs and Tables for Chemists" (1917), p. 62.

The much older expression of the same equivalence, pounds per cub. ft. × 16 = kgm. per cub. metre has appeared in various engineers' handbooks for more than twenty-five years (for example, Frye's "Civil Engineers' Pocket-Book" (1912), p. 89). Easily remembered equivalents of this kind constitute one of the first lessons learned by a laboratory worker when he goes into industry.

In the case of gases, where we generally deal with large volumes, Lunge's simple calculation ("Alkali Maker's Handbook" (1891) p. 26) based on the same equivalence of gram and ounce molecular weights, is most useful. The molecular weight of a gas divided by 4 gives the approximate weight in cwt. of 10,000 cubic feet. This may also be applied to mixtures of gases. For example, the average molecular weight of dry air, calculated as one fifth oxygen and four fifths nitrogen, is 28·8, and $\frac{28\cdot 8}{4} = 7\cdot 2$ cwt. per 10,000 cub. ft. The precise figure at N.T.P. is 7·206 cwt.

The volume of an ounce molecular weight of oxygen as visualized approximately by Dr. Drane is 22·5 cub. ft. weighing approximately 2 lb. The actual weight at N.T.P. is 2·008 lb. and calculated by Lunge's method is 2·016 lb.

I entirely agree with Dr. Drane that notes of such relationships between metric and British units might well appear in the text-books.

James Strachan.

The Orchard,
Hook Green,
Meopham,
Kent.
April 30.

* * *

The fact that the molecular weight of a gas or vapour in ounces occupies 22·4 cub. ft. at S.T.P. seems to have been pointed out first by Prof. J. W. Richards in an article on "Some Abridgments in Chemical Calculations", published in the *Journal of the Franklin Institute*, 152, 109 (1901). It is quoted as far back as the 1912 edition of Dr. J. W. Mellor's "Modern Inorganic Chemistry".

Apropos of abridgments, it does not appear to be generally known that the conversion factor from Calories per cub. m. to B.Th.U. per cub. ft., namely, 0·11236, can be represented by 1/9 + 1/800 to an accuracy of better than one part in 100 thousand.

Science Subjects at External Arts Examinations

IT will be generally agreed that workers in the field of pure science should be recruited so far as possible from the educated population as a whole and not from particular social or economic classes within this whole: where the range of intellects is wider, the resultant products are likely to be more varied and richer. Equally it is agreed that the primary aim of science is the advancement of pure knowledge as a whole, not merely of highly developed branches demanding equipment, the expense of which will tend increasingly to place originally disinterested workers in the power of less disinterested 'patrons'.

If we admit this, shall we not be the more insistent in requiring that regulations for examinations be drawn up so far as possible upon lines tending to offer wide scope to individual talent, and not upon lines which only too often seem to have *elimination*—stressing the negative sense of the word—as their principle? Referring specifically to conditions in the University of London, the arbitrary and highly undesirable selection of workers which the expense of a science degree at present often renders unavoidable might be compensated for in some measure by a far-reaching extension and broadening of the regulations for external degrees *in Arts*, and should include a relaxing of certain present restrictions as regards special fees or a transferring of these to other subjects, a knowledge of which is not so much sought after or so socially urgent.

I make the following preliminary suggestions:

(1) Sociology should be included as a subject for the B.A. General Examination. (2) Anthropology should be forthwith freed from its special fee of an *additional* five guineas. (3) Honours candidates who are prohibited by expense from taking subjects where a practical examination is necessary, should be allowed to take sociology without having to show a knowledge of Kant's "Critics". (4) Students of languages (who often show as marked an aptitude for science as they do little capacity for literary appreciation) should be offered more attractive and varied syllabuses: optional papers on the geography, history, ethnology, sociology of the country, etc.; on the lines of the present Slavonic syllabuses. (5) Some attempt should be made to separate such parts of a science as are capable of purely theoretical and critical treatment and to form these into material for the creation of additional science subjects, which may be taken by those unable to take the practical work at ordinary science examinations. It seems, in this latter case at any rate, time that such a promising division of labour were given further consideration.

ARTHUR MOLE.

13 Grafton Road,
Worthing.

Points from Foregoing Letters

LORD RAYLEIGH finds that igneous rocks in general contain about 3×10^{-2} c.c. of nitrogen per gram, mostly held in chemical combination. The ratio argon/nitrogen is much less in the earth's crust than in the atmosphere. The total nitrogen content of the rocks is many times greater than that of the atmosphere.

Prof. K. Przibram states that the different colorations of fluorites are due to the varying intensities of the absorption maxima of the bivalent rare earth ions and of the reduced calcium, and explains various colour and luminescence effects by electron transfer from the bivalent rare earth ions to the calcium and back.

Prof. E. F. Burton reports the results of experiments on the velocity of sound in the two forms of liquid helium, helium I and helium II. A graph is submitted giving the variation of this velocity with temperature; the slopes of the curves are different in the two liquids and there is an indication of a slight discontinuity at the λ-point. The value at the λ-point is 221 metres per second.

An absorption curve for Group *A* neutrons in silver with thin detectors (0·01 gm./cm.^{2}) and with thin absorbing foils (down to 0·006 gm./cm.^{2} has been obtained by Dr. H. Paxton. The absorption coefficient of 60 cm.^{2}/gm. determined from the beginning of this curve is supposed to set a lower limit for the value which would be measured with negligibly thin absorbers and detectors.

A graph showing the yield of positrons from radio-phosphorus of mass 30 (obtained by the action of polonium α-rays upon aluminium), as a function of the average range of the exciting α-particles, is given by A. Szalay.

By using a Cartesian diver method for detecting minute pressure variations, so that a change of one millionth of a c.c. of gas can be observed, Dr. J. Needham, E. J. Boell and Veronica Rogers are investigating the chemical changes in different parts of the developing amphibian embryo (gastrula).

Prof. B. C. Guha and P. N. Sen-Gupta bring further evidence in support of the view that cabbage, and also certain animal tissues, contain ascorbic acid in combined form (ascorbigen) and in addition a non-specific reducing substance in combined form. The authors outline a method for the estimation of the 'total' ascorbic acid.

D. G. Dervichian and M. Joly point out that while the flow of surface monolayers is proportional directly to the difference in pressure and inversely to the length of the channel, the dependence of the flow upon the width of the slit is complicated owing to the entrainment of water. The rate of flow gives useful information concerning change of state in monolayers.

A. Sokolow derives a connexion between electromagnetic and neutrino fields for the three-dimensional case in relativistically invariant form by assuming that the rest-mass of the neutrino is zero.

Research Items

Albanian Gypsies

Mrs. Margaret Hasluck has prepared an account of the gypsies of Albania, based partly on literary sources, and partly on her observations, of which the first instalment has appeared (*J. Gypsy Lore Soc.*, Ser. 3, **17**, 2; 1938). In Albania there are, broadly speaking, two classes of gypsies, readily distinguishable as nomads living in tents and speaking Romani as their mother tongue, and the sedentaries who live in houses and huts, and have forgotten Romani. The gypsies form a relatively large proportion of the Albanian population, as they number some 20,000 out of a total of one million. The two classes of gypsies are given different names by the Albanians, and these also vary in form and meaning according to locality. Several of these names are to be traced to the root seen in the English word "Egyptian". The houses of the sedentaries, like those of the poor Albanians, are one-storied cottages, with living-room and kitchen. They contain little furniture. In the towns the gypsies form a separate quarter. Sometimes nomads may live in a house for a period, possibly some months, and then revert to tent life. The huts are of wattle and daub, about seven feet high, and, unlike the houses, have no furniture. The tents are usually of the simplest type, the tent being thrown around the pole like a cloak, with an ever-open door. Occasionally a tent with a ridge-pole on two forked uprights is used. Quilts and straw-mats are the only bedding carried, leaves and branches serving for mattresses. The chief utensils are a pot and frying-pan. Thus at need a donkey can transport all the goods of a family. No cradles are used, and small children are carried in a sling thrown over one shoulder, which allows the child's feet to rest on the mother's hip. As linguists, the nomads surpass the sedentaries. The average nomad is taller than his sedentary counterpart, and has a lither body and darker complexion. So dark are they that a nomad woman is sometimes styled "as black as the kitchen crook". Owing to this their tongue appears unusually red and their teeth very white. Hence the Albanian belief that the gypsies have a redder tongue and better teeth than themselves. Some of the sedentary gypsies have fair hair and skin and blue eyes. This colouring others endeavour to obtain by sympathetic magic, putting a silver coin in the milk on St. George's Day and then hanging it round their necks to prevent sunburn.

Emotion and the Secretion of Urine

The fact that emotional stress and muscular exercise can inhibit the secretion of urine has been known for many years, but its cause has remained obscure. Rydin and Verney (*Quart. J. Exp. Physiol.*, 27, 343; 1938) have now carefully analysed this phenomenon. They find that the nerve supply of the kidney is not concerned in the effect, but that it is due to some circulating substance, other than adrenaline, reaching the kidney through its blood vessels. The inhibition produced by emotion can be imitated with considerable exactness by the intravenous injection of minute quantities of the active principle of the posterior lobe of the pituitary gland, and this has led the authors to suggest that a discharge into the blood stream of the anti-diuretic principle of the pituitary is the normal accompaniment of such emotional stress. The existence of nervous connexions between the hypothalamic nuclei and the pituitary body adds cogency to this suggestion, and the probability that it is a normal physiological event is supported by the extraordinary potency of very minute amounts of posterior pituitary extract. The authors calculate that an effective dose would mean the exposure of the cells of the kidney to only 30 molecules each of the anti-diuretic principle.

Density of Small Living Organisms

The *Proceedings of the Linnean Society*, 1937–38, Part 2, contains a very clear description, by Mr. A. G. Lowndes, of an experimental method by which the density of small living organisms may be determined, using the normal specific gravity bottles, in which the organisms are weighed in their natural fluid. The volume of the organism is determined by immersing it either in sea water, if a marine organism, or in a glucose solution and afterwards determining the volume of fluid displaced by the organism by a titration. A certain number of densities are given and also results of experimental test of the accuracy of the method by a comparison of the density of glass beads determined by this method and by direct determination of volume displacement and of weight. The table of densities shows that the stickleback is always denser than its natural medium, and must continually keep itself up by its own muscular effort; a more striking result is that the sinking factor in the stickleback is less at 20° C. than at 10° C. so that the higher the temperature the less the muscular effort required to keep afloat. It is argued cogently that, with small organisms of low density, surface area is the dominating factor so far as body orientation is concerned, rather than the position of the centre of gravity, so that spines or plumose setæ increasing the surface will have considerable significance in relation to orientation. (See also Nature, Feb. 12, p. 289.)

Non-Setting of Pears

Certain varieties of good quality pears blossom profusely, but are most irregular in setting their fruit. D. N. Srivastava (*J. Pom. and Hort. Sci.*, 16, 39; 1938) has investigated the problem at East Malling, using one free-cropping variety (Conference) and two shy-cropping varieties (Doyenné du Comice and Pitmaston Duchess). Two waves of dropping were observed, (1) a very early shedding of non-fertilized flowers, (2) a late and comparatively light dropping of partially developed fruits, popularly known as 'June drop'. The main cause of June drop did not appear to be lack of fertilization, since plenty of apparently healthy seeds were found in most of the fruits dropped. Individual fruit size was correlated with length of life on the tree, the larger fruits remaining attached longest, from which it is inferred that dropping is due to competition for nutrients. Cutting back the main branches to eight year old wood increased the set of fruit the same year, but reduced the number of fruit buds the following year. Ringing increased fruit-bud formation but did not improve the set of fruit, whilst bending over and tying down the main branches gave variable results both for fruit-bud formation and for fruit set. It is thought that the problem is a nutritional one.

Geological History of Indian Rivers

IN the symposium which followed the presidential address to the National Institute of Sciences of India (NATURE, 141, 797, April 30, 1938), Mr. D. N. Wadia of the Geological Survey reinforced Prof. M. N. Saha's plea for detailed investigations of Indian rivers by emphasizing how many important changes have taken place within historic times. In common with Saha, he accepts the hypothesis of a great river in early Pleistocene times (the Indobrahm of Pascoe or the Siwalik River of Pilgrim) which flowed from the east—somewhere in eastern Assam or China—along the courses of the present Middle Brahmaputra, the Ganges and the Indus to discharge into the Arabian Sea Wadia considers that tectonic movements are still taking place in the Himalayan foredeep. After the separation of the Indus and Ganges groups, the Jumna continued for long a tributary of the Punjab rivers. So late as the twelfth or thirteenth centuries A.D. the Sutlej appears to have flowed as a great river (the Hakra) into the Rann of Cutch. Wadia points out that the Himalayan rivers are cutting back and that there is a real danger of the Kali Gandak tapping the head waters of the Brahmaputra in Tibet and bringing that river—with consequences which can scarcely be even imagined—into the Gandak and Ganges. Another example of rapid changes is afforded by Rennell's map of Bengal (1786) and utterly different from the present. Dr. S. L. Hora of the Zoological Survey of India finds the hypothesis of the Indobrahm supported by the distribution of fish and that the Indus and Ganges were only separated at a very late period geologically. If such major changes are still taking place, it is clear how modern engineering works may be jeopardized without the nature of the changes being thoroughly understood.

Local Variations of Temperature

AN account of local variations of temperature within an area of a few square miles in the neighbourhood of Nottingham was read before the Royal Meteorological Society by A. B. Tinn on April 27. There were eight observation stations with a range of height above mean sea-level of only 130 ft., yet it was found that the daily minimum temperature showed local differences of more than 4° F. in the monthly mean and of 10° F. on individual days. The records of four of the stations were analysed over a period of two years—April 1935–March 1937—to discover the conditions most favourable for large differences. For minimum temperature these were winds from between north and east, fine weather, a high barometer and low humidity, although the conditions giving low minima did not always result in large differences. Rainy and windy conditions bring the differences to a minimum. Daily maximum temperatures show large differences less often, but such differences are occasionally found to amount to between 4° and 6° even in summer and to 8° or 9° in winter, extreme differences being most likely when some places remain in fog while others are in sunshine. The topography of the region does not contain any remarkable features, the high ground consisting of irregular spurs extending north-north-east from Nottingham Castle while the lowest ground is to the south bordering the River Trent. Its share in producing the observed differences did not show very clearly, doubtless owing to the limited number of stations compared with the variety of topographical nature. Attenborough, only 89 ft. above sea-level, showed the most Continental climate.

Condensation on Board Ship

A RECENT lecture before the Royal Society of Arts by J. S. Duly on "Condensation on Board Ship" contained several interesting illustrations of how well-known physical principles may be applied to large-scale commercial undertakings. He pointed out that cargoes in unrefrigerated holds have such considerable heat capacity that the temperature alters but little, even during a relatively prolonged voyage. Consequently in the tropics, the cargo is at a temperature below the dew point of the warm moist sea-air, and it follows that condensation can best be avoided, not by ventilation, as is usually assumed, but by its opposite, that is, by preventing the entrance of this air. A second point made by Mr. Duly was that for each commodity, the equilibrium moisture content is a function of the relative humidity of the air and (to a small extent) of its temperature. Consequently, in a closed space, a condition is reached in which the moisture content and the atmospheric humidity are in equilibrium. In other words, each commodity maintains around itself an atmosphere of appropriate humidity. Further, the outer layers of a cargo in bulk tend to protect the main mass from changes in moisture content, since any alteration on the outside affects the atmospheric humidity in such a direction as to oppose further change. On Mr. Duly's views, these facts account for damage by condensation being so small as is found in practice. He deduces, besides the conclusion mentioned above, that care should be taken in ship design to avoid either very hot or very cold surfaces anywhere on the walls of the cargo space, and also that the choice of the material from which containers are made is not a matter of indifference.

Orbits of Double Stars

DR. HENRY NORRIS RUSSELL has recently described a method for the rapid determination of visual binary orbits (*Mon. Not. Roy. Astro. Soc.*, 93, 8, June 1933). This graphical method was so easy to apply that two complete orbits could be computed in one day. Dr. R. v. d. Woolley has modified Russell's method for cases where the eccentricity is high, and by assuming that this is unity his graphical method is simple and capable of rapid application ("A Parabolic Double-Star Orbit", *Mon. Not. Roy. Astro. Soc.*, 98, 5, March 1938). This is applied to the double star Σ 1639. The values of the position angle and separation deduced from the elements are compared with nine normal places, and there is a very good agreement in both co-ordinates. It is not, of course, implied that the orbit is definitive, but if the object is carefully observed for a few years it is possible that the eccentricity can be determined. It is also suggested that σ_2 *UMa*, to which Halpern fitted a parabolic orbit about six years ago, should be observed for some years in order that its eccentricity may be computed.

Progress in Physics

Tributes to Max Planck

THE recent issue of the *Annalen der Physik* has been dedicated to Prof. Max Planck in honour of his eightieth birthday on April 23 (see NATURE, April 23, p. 720). Some of the twenty-two papers offered to him by his friends, colleagues and pupils may be picked out for mention here.

(1) The first paper is by N. Bohr on the quantum of action and atomic nuclei. Bohr contrasts the situation in the early days of interpretation of atomic spectra with the present situation of nuclear theory. In the atom, the weak and long-range Coulomb forces between the particles made possible the successful application of the correspondence principle. This failed only at an advanced stage of interpretation, when it was superseded by a fundamental revision of the laws governing observation in physics.

The nucleus, on the other hand, is held together by strong short-range forces with saturation properties, which couple the constituent parts to form an indivisible system. Gamow's theory of α-ray spectra gave an indication of the energy levels of this system. These cannot be explained on the assumption of individual particles moving in a fixed field of force as of the Coulomb type. The strong coupling of the particles and easy transfer of energy between them is revealed in the transformation processes of nuclei under neutron bombardment.

Fermi showed that the impinging energy of the neutron is spread over the whole nucleus, with formation of an unstable nucleus. This strong coupling thus makes a nucleus similar to an elastic system in dynamics, in which the effect of a shock will be distributed over a great number of proper frequencies forming an extended and finely graded spectrum. The energy of the bombarding particle 'heats' the nucleus and an 'evaporation' of some of the nuclear constituents may follow this process (cf. NATURE, **137**, 344 and 351 (1936).

(2) In the second paper, W. Heisenberg discusses the relevancy of the length $r_0 = e^2/mc^2 = 2{\cdot}81 \times 10^{-13}$ cm., which he considers to be one of the 'primary universal constants'. By this term are designated universal constants implying some kind of invariance of the physical laws. Examples are c, determining the Lorentz-invariance and h, determining the interchange relations and the invariance of the quantum laws against rotation in the Hilbert space. These 'primary universal constants' indicate the limits where the laws formulated for our initial domain of experience break down ($v \approx c$, $E \approx h\nu$). The length r_0 may be taken to indicate the limit down to but not beyond which the usual quantum mechanics hold. The new laws governing physics at distances less than r_0 may be expected to manifest themselves in the following phenomena:

(*a*) Self-energy and radius of the electron, Sommerfeld's fine structure constant, $\alpha = e^2/hc$. (Since $e < \sqrt{hc}$, classical explanations for these are not to be expected.)

(*b*) β-Disintegration. The present difficulties arise from imposing arbitrary limits on certain integrations; this treatment may be considered as a kind of correspondence to the treatment taking account of the new laws below r_0.

(*c*) Masses of elementary particles may be hoped to follow from r_0 in a similar way as the term values of hydrogen from h by way of the Rydberg constant.

(*d*) Interaction of particles provided the energy implied is of the order hc/r_0. This will be the case for the ordinary interaction in nuclei and for collision between particles rich in energy. Disintegration by 'explosion' may be expected if the nuclear field 'separates' from the nucleus on approaching another nucleus by less than r_0.

(*e*) Lengths less than r_0 will not be measurable, even by the γ-ray microscope, since the act of measuring would lead to nuclear explosions.

(*f*) A clue to the ultimate invariance property connected with r_0 will perhaps be obtained from relations between the observable values such as cross-sections for cosmic ray processes.

(3) R. A. Millikan discusses the "1938-values" of the fundamental constants. Acknowledging fully the importance of recent X-ray measurements by DuMond and Bollmann and by von Friesen, he arrives at:

$$e = 4{\cdot}796 \pm 5 \times 10^{-10} \text{ E.S.U.}, \; h = 6{\cdot}610 \pm 12 \times 10^{-27} \text{ erg. sec.}, \; N = 6{\cdot}097 \pm 6 \times 10^{23}.$$

(4) Two papers deal with the influence of conditions imposed on the solutions of the Schrodinger equation. E. Schrödinger finds that ψ need not necessarily be limited to single-valued functions in order to obtain unambiguous physical predictions. It is not possible, however, to have more than double-valued functions, of opposite sign in the two branches, and the same problem admits of either mono- or divalent functions only for all its states.

A. Sommerfeld and H. Welker surround an hydrogen atom by an infinitely high and steep spherical potential wall, and show that the ground state for this 'enclosed hydrogen atom' is expressed by confluent hypergeometric functions. With decreasing radius of the wall, the energy rises from its normal negative value and becomes positive when the available distance of the electron from the centre is limited to 1·835 times the normal ground state radius.

(5). Several papers are devoted to thermodynamical and statistical problems. W. Meissner goes into the details of the growth of solid carbon dioxide into liquid carbon dioxide as realized in the 'Agefko' process. A very large heat gradient exists over a boundary layer of 0·1 mm. in thickness which is traversed by capillaries 1 μ in diameter. General equations for stationary thermodynamical processes at the moving boundary between two phases are given.

Statistical considerations initiated by Gibbs and Vollmer for problems of condensation are applied by R. Becker to the segregation of the constituents of a mixed crystal. The rate of formation of crystal nuclei for further growth can be determined as a function of under-cooling for a crystal in which the binding forces act between neighbouring atoms only. This compares well with the measurements.

M. v. Laue gives a study of the thermodynamics of supra-conductors, F. Hund the theory of diamagnetic properties of very small pieces of metal at low temperatures. The heat anomalies found for alums at very low temperatures by Simon and his co-workers are attributed to the internal electric and magnetic fields of the crystal acting on the trivalent metal ion by P. Debye in a paper on cooling by adiabatic demagnetization. A detailed discussion of the iron-ammonium alum gives the Curie point at 0·038° K. as against the value 0·034° K. given by Simon from his observations. The magnetic coupling of the atoms leads to the formation of spontaneous order below a temperature of some thousandths of a degree, and prohibits a further cooling by demagnetization, which therefore will only be possible by action on the magnetic moments of the nuclei.

(6) Limitations of space forbid mention of further papers, save one by K. Schmeise and W. Bothe on a new kind of ultra-hard cosmic ray shower which seems to originate in the hard component of the primary cosmic rays. These showers scatter over an angle of about 10°, half that of normal showers, and are transformed into the ordinary soft showers on passing through matter.

The Problem of Stellar Energy

THE problem of stellar energy was the subject of discussion of the Fourth Annual Conference on Theoretical Physics sponsored by the George Washington University and the Carnegie Institution of Washington, and held in Washington, D.C., on March 21–23. The Conference was attended by astrophysicists studying the internal constitution of the stars (S. Chandrasekhar, B. Strömgren, T. Sterne, D. Menzel and others) as well as by physicists working on different branches of nuclear physics (H. Bethe, G. Breit, G. Gamow, J. v. Neumann, E. Teller, M. Tuve, L. Hafstad, N. Heydenburg and others).

On the fundamental problem concerning the nuclear transformations as the source of energy of stars, some interesting conclusions have been reached. According to the so-called "aufbauhypothese", the process of the building up of the heavier elements from hydrogen is continually taking place in stellar interiors. Further, it is assumed that such processes liberate sufficient amounts of energy to account for the radiation of the stars. However, it seems that the model scheme proposed by von Weizsäcker (${}^{4}_{2}\mathrm{He} + {}^{1}_{1}\mathrm{H} \rightarrow {}^{5}_{3}\mathrm{Li} \rightarrow {}^{5}_{2}\mathrm{He} + \beta^{+}$) is contradicted by recent experimental evidence, according to which the nuclei ${}^{5}_{3}\mathrm{Li}$ and ${}^{5}_{2}\mathrm{He}$ are both unstable, emitting heavy particles in a very short time. Another possible chain of reactions for the synthesis of the heavier elements from hydrogen and helium would require the stability of ${}^{8}_{4}\mathrm{Be}$, which is again very doubtful according to recent experimental evidence. It appears, then, that the only course not excluded by present evidence on the binding energies of the light nuclei is the formation of ${}^{6}_{4}\mathrm{Be}$ in triple collisions involving an α-particle and two protons.

Although the existence of ${}^{6}_{4}\mathrm{Be}$ has not yet been established experimentally, there are some indications that it might be a stable nucleus. If so, the chain of reactions leading to the synthesis of the heavier nuclei from hydrogen can be traced. The estimate of the probability of such reactions involving triple collisions shows that, under the conditions in the stellar interiors, the rate of liberation of energy will be sufficient to account for the radiation of the stars.

As another possibility the reaction ${}^{1}_{1}\mathrm{H} + {}^{1}_{1}\mathrm{H} \rightarrow {}^{2}_{1}\mathrm{H} + \beta^{+}$ was suggested. It seems that the rate of such a reaction under the conditions in stellar interiors would be just enough to account for the radiation of the sun, though for stars much brighter than the sun other more effective sources of energy are required.

Special attention was directed to the possibility of resonance effects for nuclear reactions occurring in the interior of the stars; in such cases it would be necessary to consider that some light nuclei have virtual levels in the region of 10 kv. (corresponding to temperatures of the order 4×10^7 degrees Kelvin). The presence of resonance levels would not only increase the rate of liberation of energy of the reaction in question, but also would at the same time require a rather different type of stellar model. The rate of ordinary nuclear reactions increases exponentially with temperature, leading effectively to a point-source model in which the energy sources are concentrated at the centre. The selectivity with respect to temperature which would arise from resonance levels at about 10 kv. would, on the other hand, suggest a shell-source model with the maximum liberation of energy in a spherical shell surrounding the centre. It seems that this new model has a number of advantages over the point-source model.

The possibility of an extremely dense neutron core at the centre of the star (as proposed by L. Landau) was also discussed. The study of a number of known stars does not indicate a central condensation of more than what corresponds to 90 per cent of the total mass within half the radius. Thus, so far as astrophysical evidence is concerned, the model of a star with a heavy 'stellar nucleus' at the centre is *not* confirmed, except possibly for supergiants (for example, the *M*-component of vv Cephei, the infra-red component of ε Aurigæ), for which cases the observational evidence allows one to infer a high degree of central condensation corresponding to 90 per cent of the mass within less than ten per cent of the radius. Further, a stellar model with a 'nucleus' would require extremely high temperatures and densities ($\sim 10^9$ degrees and $\sim 10^9$ gm./cm.^{3}) at the surface of the core. In such physical circumstances *all* nuclear reactions would occur at extremely high rates and the total liberation of energy would lead to predicted luminosities for stars of altogether different orders of magnitude from those observed. It was therefore concluded that stellar models with a concentrated nuclear core cannot represent real stars.

S. Chandrasekhar (Yerkes Observatory).

G. Gamow (George Washington University).

M. A. Tuve (Carnegie Institution of Washington).

Elliot Smith Memorial

ON Tuesday, May 3, in the Thane Library of the Faculty of Medical Sciences, University College, London, a bust in bronze of the late Sir Grafton Elliot Smith, professor of anatomy in the College from 1919 until 1936, was unveiled by Prof. J. T. Wilson and presented by him on behalf of the subscribers to the chairman of the College Committee (the Right Hon. Viscount Sankey of Moreton). Prof. J. P. Hill reported on behalf of the Committee that the subscribers to the Fund included old friends, colleagues and pupils of Elliot Smith from all the continents, and most of the countries of the world. The execution of the memorial was entrusted to Mr. A. H. Gerrard of the Slade School, and the bust is a striking portrayal of a man of vigorous personality and great intellectual capacity.

In making the presentation, Prof. Wilson, in a short speech of singular charm and warmth of feeling, remarked that Elliot Smith's best memorial is not material but spiritual and is to be found in the impressive record of his lifelong activity and in his influence on innumerable people besides his pupils, colleagues and friends. The qualities that his friends have recognized have been an extraordinarily penetrating vision and a capacity for interpretation, together with a striking vigour and clarity of exposition. Prof. Wilson made mention of the very varied character of Elliot Smith's career as an anatomist, first in Sydney, then in Cambridge, followed by Cairo, Manchester and finally London, and of how all these manifold experiences influenced the trends of his remarkable activities. He recalled that some forty-five years ago, Elliot Smith had been his pupil in the University of Sydney and afterwards his demonstrator, and speaking as the representative of his Alma Mater, he further recalled with pleasure that he had had the honour of recommending him for one of his first distinctions, the Gold Medal awarded for his thesis for the doctorate.

Lord Sankey, in accepting the bust on behalf of the College, said it was a remarkable memorial to a remarkable man and yet another treasure to the gallery of great and distinguished men who by their life and learning have contributed to the prestige of University College.

The Provost of the College, Sir Allen Mawer, in thanking Prof. Wilson and the subscribers, spoke of the part played by Elliot Smith in the negotiations with the Rockefeller Foundation which resulted in the munificent benefaction through which it was possible to build and equip the existing Department of Anatomy, and of his influence in promoting the close association which exists between the College and the universities of the Dominions and more particularly of Australia.

Immunological Reactions of the Filterable Viruses

ONE of the greatest services which a group of investigators can give to the larger scientific public is the compilation of a sound and detailed résumé of their own particular field of research. F. M. Burnet, E. V. Keogh and Dora Lush have done this for the immunological reactions of the filterable viruses (*Aus. J. Exp. Biol. and Med. Sci.*, 15, Pt. 3 (supplement), pp. 231–368; 1937: also published separately, price 10*s*. 0*d*., from the Librarian, Univ. of Adelaide, South Australia, or Messrs. H. K. Lewis and Co., Ltd., 136 Gower Street, London, W.C.1). The specialist contribution of these workers lies mainly in their quantitative study of the immunity reactions of numerous animal viruses, using a method which produces discrete pock marks upon the chorioallantoic membrane of a developing egg. Their present monograph contains a short reference to the serology of plant viruses, but is otherwise devoted in detail to those which attack bacteria and mammalian animals. Chapter I contains a useful comparison of animal viruses with bacteriophages. The latter can be regarded as virus diseases of bacteria, and have particle-sizes commensurate with the small size of their hosts. They range from 10 to 65 mμ in diameter, where animal viruses vary between 10 and 300 mμ. Both are composed mainly of nucleoprotein, with traces of ether-extractable substances and salts, whilst carbohydrates are lost during washing.

The section describing the immunology of bacteriophage is, of necessity, more general than that setting forth the comparable reactions of animal viruses. Specificity of bacteriophage inactivation by immune sera, differences in antigenicity among bacteriophages, and the antigenicity of inactivated phage, are some of the main lines of discussion, whilst the details of typical phage-antiserum reactions are given at considerable length.

It is possible to be much more specific in the sections which deal with the immunology of animal viruses. The causal agents of influenza, cow-pox (vaccinia), louping-ill, rift valley fever, equine encephalomyelitis, Newcastle disease, infectious laryngotracheitis and myxomatosis, are each given a particular chapter, wherein their immunology is adequately portrayed. Chapters upon virus immunity from a biological point of view, on the site of formation of virus antibodies, on the principles of active immunization against virus infections, and on modern views upon the antigen-antibody reaction, minister to the more general reader in search of biological background.

Considerable lists of references to the literature are given, and if the Australian investigations are emphasized somewhat, workers in the northern hemisphere can only be grateful for their concomitant availability, and be glad of such fundamental contributions. It would indeed be difficult to over-emphasize the value of such monographs as the one under review; it serves to nullify any incipient bewilderment at the increasing volume of modern knowledge in its particular sphere.

Science News a Century Ago

Geographical Exploration

ON May 28, 1838, at a meeting of the Royal Geographical Society, six communications were read. These referred to the discovery of the outlet of the River Murray in Australia; the expedition of Thomson D'Abbadie to Abyssinia; a journey in north-west Persia by Lieut.-Colonel Shiel; some observations from Bagdad by Lieut. Lynch, who had examined the banks of the Tigris from its source to that city; a proposal from G. A. Hoskins sent in the name of the Society of Egyptian Travellers suggesting sending a native of Dongola to explore the western branch of the Nile, and a communication from Schomburgk in British Guiana dated November 18, 1837. Ascending the Rivers Essequibo, Rewa and Quitaro "we halted," wrote Schomburgk, "on the 7th Nov. in order to visit the Atáraipú, a natural pyramid, of which I had heard so many and such contradictory reports. Our road to it led through thick woods, until after a scramble of two hours we stood at the foot of a hill of gniess, barren with the exception of a few parasitic plants as Orchideæ, Cacti, Chusia, which draw their scanty nourishment from a thin layer of vegetable mould lying in the clefts of the rocks. After ascending for 300 feet, the view opened to the west, and from the abyss below rose the far-famed Atáraipú, one of the greatest natural wonders of Guayana. Its base is wooded for about 350 feet high from thence rises the mass of granite, devoid of all vegetation, in a pyramidical form, for about 550 feet more, making its whole height 900 feet above the plain . . . a little to the south of it another, almost similar of gneiss, of which, when we consider that all beyond was unknown ground, it might well be said, in the words of the poet, that they

"Like giants stand
To sentinel enchanted land."

Blowing up of a Sunken Vessel

CONSIDERABLE interest was taken in the blowing up by means of gunpowder, on May 28, 1838, of the coal brig *William*, which in 1836 had sunk in the River Thames off Gravesend, with about 300 tons of coal aboard. According to the *Mechanics' Magazine*, this was the first attempt to destroy a vessel under water. The task of destruction was entrusted to Colonel (afterwards General Sir) C. W. Pasley (1781–1861), director-of the Royal Engineers' Establishment at Chatham. Two leaden cylinders each containing 2,500 lb. of gunpowder were made. These were completely enclosed in wooden cylinders of 3 in. timber, 4 ft. in diameter and 10 ft. long, bound with hoop iron. One of the cylinders was placed in position by divers and the charge was exploded by means of a fine powder hose in a flexible leaden pipe attached to the cylinder, the upper end of which was moored to a red buoy. The gunpowder train was connected with a small tin canister in the centre of the great charge. A sapper with a lighted taper set fire to the fuse, which burnt five minutes, allowing him to row out of danger. The explosion raised a dome of water 800 ft. in diameter 70 ft. high. Much the same methods were used by Pasley a year or two later in destroying the *Royal George*, except that electricity was used for firing the charge.

The Greenwich Lunar Observations

"ON May 31, 1838, the Treasury assented to the undertaking of the Lunar Reductions and allotted £2,000 for it; preparations were made, and in the autumn 7 computers were employed upon it" (Airy). "The reduction of the Greenwich lunar observations from 1750 to 1830," says Grant, "was undertaken at the public expense in consequence of a representation to that effect having been made to the Government by the British Association, agreeably to a suggestion of Sir John Lubbock's on the occasion of the meeting of the Association, which was held in Liverpool in 1837. The organization of the plan of reduction, as well as the superintendence of its execution, was confided to Mr. Airy. In consequence of the multitude of inequalities by which the moon's motion is affected, the undertaking was one of stupendous magnitude. In order to form some idea of the labour expended in its execution, it may be mentioned that upwards of 8,000 places of the moon were deduced from the observations, and compared with the corresponding places calculated from the tables. . . . The calculations connected with this great undertaking were superintended by Mr. Hugh Breen, who had the melancholy satisfaction of just living to see its completion. Mr. Airy, who bears honourable testimony to his skill and accuracy, states, at the beginning of the first volume of the published results, that after a short illness he expired on the morning of April 1, 1848, only a few hours having elapsed after the last supplementary tables had been sent to the press."

Influence of Nitrogen on Growth of Plants

AT a meeting of the Royal Society on May 31, 1838, Robert Rigg read a paper entitled "An Experimental Inquiry into the Influence of Nitrogen on the Growth of Plants". After alluding to a previous paper describing the chemical changes which occur during the germination of seeds, the author proceeded to trace the connexion between the phenomena exhibited during the growth of plants and the direct agency of nitrogen. The results of his experiments were arranged in tables indicating in about 120 different vegetable substances, not only the quantities of carbon, oxygen, hydrogen, nitrogen and residual matter, but also the quantity of nitrogen in each compound, when compared with 1,000 parts by weight of carbon in the same substance. The most important tables were those which exhibited the chemical constitution of the germs, cotyledons, and rootlets of seeds; the elements of the roots and trunks of trees, and the character of the various parts of plants, especially of the leaves at different periods of their growth. From his observations it appeared that nitrogen and residual matter are invariably the most abundant in those parts of plants which perform the most important offices in plant physiology, and the author was disposed to infer that nitrogen (being the element which more than any other is permanent in its character) when combining with residual matter, is the moving agent, acting under the living principle of the plant, and moulding into shape the other elements.

Spanish Bells

THE issue of the *Gentleman's Magazine* for May 1838 contains the following information: "In consequence of the difficulties to which the existing government of Spain has been reduced in the war with Don Carlos, a large quantity of bells, which were the property of the convents and were transferred from them for the relief of the Queen's cause, were sent to Marseilles and sold as old metal. About sixty were purchased by an American gentleman and shipped to New York, where the most experienced bell-founders examined them and pronounced that they are such that cannot be made in America, nor probably anywhere at this time. It is well known that the ancient Spanish bells and indeed all the old bells cast in Catholic countries were considered as sacred; the more precious their metal, the greater their sanctity, and nearly all of them are thought to have more or less silver in their composition. The art of compounding silver with the other metals entering into the composition of bells is now entirely lost. The tones are said to be inimitably beautiful; and it is stated that one of these bells weighing 100 pounds has as much power and strength of tone as an ordinary bell weighing 300. They weigh from 100 to 1700 pounds each; and are often highly ornamented with figures of the Cross, royal Arms of Spain and various devices *in alto relievo.* After being a certain time on view at New York, they were dispersed by public sale, and will now be scattered about in every quarter of the States. . . . The largest weighing 1700 pounds is already doing duty on the top of the New York City Hall."

University Events

BELFAST.—Mr. A. H. Naylor has been appointed professor of engineering as from October 1, in succession to Prof. F. Hummel, who is retiring. Mr. Naylor is at present research officer of the Institution of Civil Engineers.

LEEDS.—Dr. D. T. A. Townend has been appointed Livesey professor of coal gas and fuel industries, to take office from October next, in succession to Prof. J. W. Cobb (see p. 964).

LONDON.—Prof. H. H. Read has been appointed, as from January 1, 1939, to the University chair of geology tenable at the Imperial College of Science and Technology. Since 1931 he has been George Herdman professor of geology in the University of Liverpool.

Dr. G. R. de Beer has been appointed to the University readership in embryology tenable at University College. For the last eleven years he has been Jenkinson lecturer in embryology and senior demonstrator in zoology and comparative anatomy in the University of Oxford.

The title of professor of natural philosophy in the University has been conferred on Dr. Herbert Dingle, in respect of the post held by him at the Imperial College—Royal College of Science.

The following doctorates have been conferred: D.Sc. in biochemistry on W. T. J. Morgan, of Queen Mary College, Lister Institute of Preventive Medicine, and West Ham Municipal College; D.Sc. in botany on A. E. Muskett, of the Imperial College—Royal College of Science; D.Sc. in chemistry on H. N. Rydon, of the Imperial College—Royal College of Science.

The Dunn exhibitions in anatomy and physiology for 1938 have been awarded to Mr. S. D. V. Weller (of University College) and Mr. J. W. L. Doust (of King's College) respectively.

Societies and Academies

London

Royal Society (*Proc.*, B, 125, 187–290, April 27, 1938).

D. KEILIN and T. MANN: Polyphenol oxidase: purification, nature and properties.

J. MELLANBY and C. L. G. PRATT: The coagulation of plasma by trypsin.

A. S. PARKES and I. W. ROWLANDS: Studies on the hypophysectomized ferret. (10) Growth and skeletal development.

E. C. DODDS and W. LAWSON: Molecular structure in relation to œstrogenic activity. Compounds without a phenanthrene nucleus.

P. N. MARTINOVITCH: The development *in vitro* of the mammalian gonad: ovary and ovogenesis.

H. G. SMITH: The receptive mechanism of the background response in chromatic behaviour of Crustacea.

H. WARING: Chromatic behaviour of elasmobranchs.

LORD ROTHSCHILD: The polarization of a calomel electrode.

Dublin

Royal Irish Academy, April 25.

A. FARRINGTON: The glaciers of Mount Leinster and Blackstairs Mountain. The moraines of the local glaciers are described and their relations to one another discussed. The level of the snow-line during the late glacial period is estimated at 1,650 feet O.D.

Edinburgh

Royal Society, May 2, 1938.

R. CARRICK: The life-history and development of *Agriolimax agrestis* L., the grey field slug. Seasonal activity, copulation, oviposition, hatching and growth of *Agriolimax agrestis* are dealt with. There is no seasonal sexual cycle, but reproductive activity is controlled directly by weather conditions and is most evident during August-November. Under field conditions, the incubation period varies from 21 to 96 days. Embryological points of interest are fusion of the third tentacles, development of large contractile sacs, direct transition of blastopore into mouth, and the composite structure of larval nephridia from mesodermal bands and ectodermal invaginations. The structure and function of the modified larva, associated with development within the albuminous egg-capsule on land, are compared with less specialized gasteropods.

EDITH A. T. NICOL: The brackish-water lochs of Orkney. The brackish-water lochs of Orkney are the only Scottish localities where *Neritina fluviatilis* L. is found. The Loch of Stenness is entered by spring tides and has a salinity varying between 10·2 and 26·8 per cent. Its fauna and flora are mainly brackish in character, but many marine forms occur. The Loch of Stenness flows into the other and has a low salinity, 0·8–4·3 per cent, and many freshwater species occur along with brackish ones. The calcium contents in both lochs varies between 56 and 139 mgm. per litre, which partially accounts for the presence of *Neritina.*

MARIE E. CAMPBELL: An investigation of the Mucorales in the soil. Fifteen soil samples were taken from seven distinct soil types and the species of *Mucor* were isolated in pure culture. The results show that there is no well-marked *Mucor* association for the soil types. Certain species such as *Mucor hiemalis* and *M. racemosus* occur in almost all soils. The proportion of positive to negative forms of *M. hiemalis* in the soil was found to be 25 : 4. By experiment it has been shown that the positive hyphæ of *M. hiemalis* are more resistant to drying than the negative hyphæ. Hybrid zygospores have been obtained between different species of the same genus and also between different genera of the Mucorales.

D. Meksyn : Green's function for an ellipse and its application to the motion of a point vortex. Green's Function for the space external to an infinitely long elliptic cylinder, and for the space enclosed between two such confocal cylinders are evaluated. The stream lines and the motion of a rectilinear vortex outside an elliptic cylinder are found.

Paris

Academy of Sciences, March 28 (*C.R.*, 206, 961–1064).

Charles Eugène Guye : Relativity, resonance and molecular diffusion.

Jean Bosler : Earth currents and magnetic disturbances. From a study of the records of the Parc Saint-Maur Observatory it is shown that the variations of the N–S earth currents follow those of the magnetic declination and those of the E–W current those of the horizontal force. A general principle is enunciated: when two phenomena are such that the curves which represent them as a function of the time are parallel, the two are related by a law of proportionality.

Jean Ville : A continuous game. Discussion of a problem in probability.

Aryeh Dvoretzky : The abscissæ of holomorphy and meromorphy of analytical functions represented by Dirichlet series.

Jean Legras : An integral equation with principal part.

Hubert Delange : The domain of absolute convergence of multiple series of powers.

V. A. Kostitzin : The singular points of the differential equations of the problem of natural selection.

Chi Tai Chuang : The behaviour of a holomorph function in a circle.

Michel Kiveliovitch : Hydrodynamic equations and quantic statistics.

René Anthouard : Some characters of sparks submitted to an air current.

Mlle. Edith Couillaud : Concerning physical tests for cement. Tests on cement in different laboratories, made in every detail in accordance with a rigorous specification, show differences of 4–15 per cent. Replacement of hand mixing by mechanical mixing in the preparation of the test pieces is suggested as likely to lead to greater concordance in the results.

Pierre Dive : Analyticity of the square of the angular velocity of a fluid star.

Santiago Antunez de Mayolo : The principle of the critical velocity in the materialization of the photon.

Gérard Petiau : A form of the solutions of the Dirac equations and the equations of the photon.

Jean Guastalla : A new technique for the measurement of very small surface pressures.

Pierre Vernotte : The practical determination of the relative values of the thermal conductivity of metals.

Jean Savard and Marc de Hemptinne : The simple critical potentials of carbon monoxide.

Robert Guillien : The dielectric constant of carbon disulphide at a low temperature. The experiments of Mazur indicated an anomaly for the dielectric constant at about − 90° C., pointing to the existence of two different liquid states of carbon disulphide. The author has been unable to confirm this; provided that the liquid is efficiently stirred no anomaly exists between + 20° C. and − 110° C.

Bruno Pontecorvo : The diffusion of monokinetic neutrons by protons.

René Audubert and J. Mattler : The influence of vapours on the curve of spectral sensibility of photo-electric counters.

Pierre Lambert and Jean Lecomte : The application of infra-red absorption spectra to the determination of the position of the ethylene linkage in a fatty carbon chain.

François Gans : The spectral distribution of the white light obtained by electrical stimulation of xenon. The tubes studied contained either xenon or a mixture of xenon and neon. The energy distribution of the continuous spectrum was very nearly the same as that of a black body at 3,800° C. The lines showing were xenon lines only; no neon lines were seen.

Jules Farineau : The *L* spectrum of iron.

Marcel Frilley : The spectrography by diffraction of the γ-rays of actinium and of its derivatives.

André Moussa and Mlle. Hélène Laurent : The periods of disintegration of the radio-silvers.

Yves Deux : The semihydrobenzoin transposition of phenylmethylvinylglycol by dehydration and by the isomerization of the corresponding epoxide.

Marcel Tuot : The secondary reactions observed in the course of the organo-magnesium condensation of ketones in the fatty series. Study of two secondary reactions produced by the enolization of the ketone by the action of the Grignard reagent.

François Salmon-Legagneur : A new structural isomer of campholic acid : β-campholic acid.

Jean Décombe and Clément Duval : The double formula of organo-magnesium compounds. Support for the hypothesis of the double formula for organo-magnesium compounds is given by the formation of a zinc-magnesium complex compound by the action of a zinc-magnesium alloy on methyl iodide in ethyl acetate solution.

Maurice Métra, Lucien Lesage and Fernand Descatoire : The detection of small quantities of isopropanol in alcohols. The method described has been applied to the examination of more than a hundred specimens of ethyl alcohol from various sources : in no case was isopropyl alcohol detected.

Raymond Paul : The influence of the nature of the cycle on the physical properties of some 1,4 and 1,5 isomeric epoxides.

Paul Gaubert : Role of the foreign matter in the structure of liquid crystals.

Jacques Flandrin : The relations of the deposits with Medjano-Numidian facies and of the Oligocene with Lepidocyclines in the littoral and tellian chains of the Department of Algiers and the adjacent regions.

Jean Cuvillier: The presence of Miogypsines in the Egyptian Miocene.

Jean Bricard: Study of the coronas of the natural fogs at the summit of the Puy de Dôme.

André Mirimanoff: Ascorbic acid and the carotenoid pigments. The meaning of the Molisch reaction and attempt at the localization of ascorbic acid.

Joseph Lefèvre: Polarity problems produced on plant cuttings by various substances.

Victor Vincent, Jean Herviaux and Yves Coic: Liming acid soils by natural limestones and agricultural lime.

Georges Deloffre: The influence of some organic acids on nuclear metabolism and on amylogenesis in the lupin.

Maurice Piettre: Mechanical treatment of defibrinated blood or blood rendered incoagulable.

Mme. Andrée Drilhon: The alexic power the sera of the Teleosteans.

Mme. Yvonne Jérome-Lévy: Cultures of the lower plants such as *Aspergillus niger*, *Aspergillus repens* and *Penicillium glaucum* in the presence of carbon. A marked increase in the development of *Aspergillus niger* is shown when carbon is added to the culture fluid (Raulin). With *Aspergillus repens* there is a slight increase of growth; no increase of weight is shown by *Penicillium glaucum*.

Mme. Paulette Chaix: The influence of treated cystine on the Pasteur effect in washed *Propionibacterium pentosaceum*.

Jean Lavollay and Mme. Françoise Laborey: The circumstances in which yellow pigments appear in the culture fluid of *Aspergillus niger*. The production of the yellow pigment is due to a deficiency of magnesium.

André Donatien and Fernand Lestoquard: The evolution of the agent of Rickettsian conjunctivitis of ruminants.

Michel Machebœuf, Joseph Dieryck and Mme. Blanche Dieryck: The comparative study of the phagocytal reaction of guinea pigs with intraperitoneal injection of dead tubercle bacilli and of bacilli partially deprived of lipids (chemicovaccine).

Daniel Florentin: The coli bacillus flora of cheese and food poisoning. The presence of coli bacilli in various cheeses was proved, one of which, containing the largest number of bacilli per gram, had been the cause of food poisoning. It is regarded as rather alarming that, whilst the coli bacillus is prohibited in water, oysters, etc., the consumption of certain cheeses leads to the absorption of considerable quantities.

Spiro Livierato, Marino Vagliano and Nearchos Kokaraki: Two new antigens for the sero-reaction of paludism according to Henry's method.

Moscow

Academy of Sciences (*C.R.*, 18, No. 3, 1938).

I. M. Rapoport: The inverse problem of the variation calculus.

A. Bermant: Some properties of regular functions.

M. Ielchin: Problem of oscillation for the linear differential equations of second order.

E. R. Mustel: The problem of radioactive equilibrium of a stellar atmosphere when the coefficient of absorption depends on the frequency.

V. Stepanoff: The definition of probability of stability.

M. Bebоutoff: Dynamic systems which are stable in the sense of Liapounoff.

I. Malkin: On the stability of movement in the first approximation.

I. Malkin: Generalization of the fundamental theorem of Liapounoff on the stability of movements.

P. Novikoff: The inverse problem of the potential.

B. G. Špakovskij: Propagation of supersonic waves in liquids. (1) Dispersion in some pure liquids and aqueous solutions. (2) Dispersion in acetic acid.

E. Reichrudel and G. Spivak: Influence of magnetic field on the potential gradient in plasma.

A. Filippov, A. Gdanow and I. Gurevich: The disintegration of nuclei by cosmic rays.

A. A. Trapeznikov and P. Rehbinder: Mechanical properties (viscosity, rigidity and strength) of adsorption layers and their relation to the area per molecule and nature of underlying liquid.

A. A. Sapeghin: The course of the development of wheat ear.

G. N. Eremejev: Drought resistance and dehydration resistance of plants.

G. Abolina: The significance of mineral elements in the process of vernalization.

M. S. Jakovlev: The endosperm structure of the principal selection varieties of wheat of the U.S.S.R.

A. A. Yatsenko-Khmelevsky: The discoloration of beech wood.

L. N. Žinkin: Stimulation of metamorphosis in Ascidian larvæ.

Rome

National Academy of the Lincei (*Atti*, 26, 129–191; 1937).

G. Fano: Observations on some finite geometries (2).

O. Scarpa: Formation of pseudo single crystals in the electro-deposition of copper.

C. Agostinelli: Resolution by means of definite integrals of the equation

$$\frac{\delta^2 u}{\delta x^2} + \frac{\delta^2 u}{\delta y^2} + \frac{\delta^2 u}{\delta z^2} + \frac{1}{x}\frac{\delta u}{\delta x} = f,$$

and a problem analogous to that of Dirichlet for a hemispherical field.

G. Gherardelli: Cayley groups of points above an elliptical curve.

I. Popa: Projective-differential geometry of singularities. The point of inflexion of any surface whatsoever.

M. Schonberg: The function $\delta(x)$ of Dirac (2).

A. Terracini: A possible particularity of the principal lines of a surface (2).

E. Medi: Researches on the ionization produced by the evaporation of water.

R. Manzoni Ansidei: Raman spectrum of hydrocarbons with condensed nuclei (2). 9-10-dihydroanthracene, acenaphthene, fluorene.

G. Charrier and M. Iorio: 8-substituted 2-3 pyridinotriazoles.

G. Tedeschi: Rate of dissolution of lead in acids (2).

G. Scoz and E. Tria: Ascorbic acid content of the frog's liver under various experimental conditions.

E. Tria: Electrometric determination of peptic activity.

Forthcoming Events

Tuesday, May 31

Fuel Research Station, Greenwich, S.E.10, at 2–6.—Annual Visitation.

Royal Anthropological Institute, at 8.30.—Prof. F. Weidenreich: "Did *Sinanthropus* Practise Cannibalism?"

Institution of Gas Engineers, May 31–June 3.—Annual General Meeting.

Association of Teachers in Technical Institutions, June 4–7.—Annual Conference to be held at Leeds.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant Lecturer in Chemistry in the Bradford Technical College—The Principal (May 31).

Geologists in the Geological Survey and Museum of Practical Geology—The Director, Geological Survey and Museum, Exhibition Road, South Kensington, S.W.7 (May 31).

Lecturer in Electrical Engineering in the Carlisle Technical School—The Director of Education, Education Offices, Fisher Street, Carlisle (June 1).

Lecturer (woman) in Mathematics in the Bingley Training College—The Education Officer, County Hall, Wakefield (June 2).

Lecturer (woman) in Mathematics in the Avery Hill Training College—The Education Officer (H. 2/1), County Hall, London, S.E.1 (June 8).

Lecturers in Building, Production Engineering and Workshops Practice in the Central Technical College, Birmingham, 1—The Principal (June 11).

Analytical Chemist in the Government Chemical Laboratories, Khartoum—The Controller, Sudan Government, London Office, Wellington House, Buckingham Gate, London, S.W.1 (June 11).

Principal of the Scarborough Evening Institutes—The Secretary, Education Offices, County Hall, Northallerton (June 11).

Assistant Lecturer in Mathematics in the Royal Holloway College, Englefield Green, Surrey—The Principal (June 11).

Demonstrator in Civil and Mechanical Engineering in the University of Leeds—The Registrar (June 13)

Demonstrator in Bacteriology in the University of Leeds—The Registrar (June 13)

General Secretary of the Society for the Protection of Science and Learning—Prof. C. S. Gibson, Guy's Hospital, London, S.E.1 (June 15).

Curator of the Verulamium Museum—The Town Clerk, Municipal Offices, 38 St. Peter's Street, St Albans (June 28).

Medical Secretary and Registrar to the Clinical Cancer Research Committee of the British Empire Cancer Campaign—The General Secretary, 11 Grosvenor Crescent, London, S.W.1 (June 30)

Lecturer in Mechanical Engineering in the School of Engineering at Khartoum—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1 (July 1).

Principal of the Imperial College of Tropical Agriculture, Trinidad—The Secretary, Imperial College of Tropical Agriculture, 14 Trinity Square, London, E C 3 (July 9).

Professor of Metallurgy and Assaying and Director of the Minerals Research Laboratory in the University of the Witwatersrand—The Secretary, South Africa House, Trafalgar Square, London, W.C.2 (July 30).

Assistant Keeper on the Higher Technical Staff of the Industrial Engineering Division of the Science Museum—The Director, Science Museum, South Kensington, London, S.W.7.

Scientific Worthies

XLVIII. Sir Frederick Gowland Hopkins, O.M., F.R.S.

If we consider the development of organic chemistry from its early beginnings to the present day, we may come to the conclusion that progress has in some measure taken place in a circle. In the early days the substances offered by Nature and occurring in the metabolism of plants and animals were the objects of investigation, and the isolation, purification and analysis of such substances have added lustre to the names of many chemists. Interest in the chemical elucidation of 'natural products' did not indeed decline during the past century (we need only mention the investigations of Emil Fischer on the purines, carbohydrates and proteins), but relatively this work absorbed less energy and yielded fewer results in comparison with the great problems of structural chemistry and the classification of organic compounds based thereon.

The building of the edifice of organic chemistry in the second half of the nineteenth century was an experimental achievement almost unequalled. Although important theoretical and practical problems still remain to be solved by organic chemistry, we can, nevertheless, recognize that since the beginning of the present century many leading representatives of the discipline are desirous of applying the experience and systematic knowledge already gained to a still more important problem, the elucidation of vital processes.

The trickle which a hundred years ago supplied the stimulus for the chemical investigation of animals and plants, has swollen to a mighty stream, and in the same measure the methods and the experimental resources of the modern chemist have multiplied. Whilst round about the year 1820 only two or three dozen organic compounds were known (naturally those which are most abundant and most easily isolated), there is to-day an ordered system among the very diverse materials which build up the plant and the animal, and the individual substances composing them have been separated. The perfection of micro-methods, both preparative and analytical, has enabled the investigator to enter a field previously inaccessible, to tackle substances which previously eluded him on account of their minute concentration. At the same time, the application of the resources of classical organic chemistry has made possible the synthesis of highly complicated natural products ; the importance of this work is obvious when compared with the first 'bio-synthesis', of urea, more than a hundred years ago.

We should, however, clearly grasp that the development of organic chemistry during the present century, thus briefly indicated, is only preliminary to the investigation of the chemical reactions which take place in the living cell. Yet for the study of these reactions such a preliminary was quite indispensable. Without accurate chemical knowledge of all the substances taking part in metabolism, the greatest problem of biological research, the elucidation of vital processes, entirely lacks foundation. We have only to imagine how far the study of the biological degradation of polysaccharides would have proceeded without the most complete knowledge of the constitution and configuration of the substances formed in this process.

The analytical branch of biochemical research is itself only a subsidiary science, albeit very important and indeed indispensable, yet ancillary to that discipline which for purposes of classification should be separated off as physiological chemistry or dynamic biochemistry. The methods of the analytical branch are essentially the same as those of the pure organic chemistry, and hence it does not seem expedient, for example, to describe as a biochemist one who is engaged in the elucidation of the constitution of an alkaloid or of a vegetable colouring matter. His work differs neither in nature nor in purpose from that of a chemist who aims at explaining the constitution of a constituent of coal tar or of some condensation product produced *in vitro*.

The elementary chemical foundations of the physiology of nutrition were the first to be laid down. The three chief divisions of food materials—the carbohydrates, the fats and the proteins—were already fairly well known, when in the last quarter of the nineteenth century the processes of digestion were studied and when, especially with the aid of the heats of combustion, the energy balance of warm-blooded animals could be drawn up. The physiological problem of nutrition seemed to have been solved. The administration of the requisite number of calories, calculated from the total metabolism and supplied in the form of the three main groups, with due regard to the protein requirements indicated by the nitrogen metabolism, was thought to be the practical solution of the problem, verifiable by animal experiment. This was a time when restaurants in many countries listed on their bills of fare the calorie value of the dishes supplied to their patrons.

It was about this time that Frederick Gowland Hopkins entered the scientific arena. Born in 1861, he did not take up the study of medicine until rather late—at twenty-seven years of age. Chemistry he had taught himself, and it is indicative of his leaning towards this subject that one of his first scientific investigations was devoted to a quite difficult chemical problem, that of the white wing-pigments of butterflies (Pieridæ). Among other leading results of his purely chemical work the isolation of tryptophane and of glutathione deserve special mention. They show at the same time where the centre of Hopkins' biochemical interests lies, namely, in protein.

Hopkins' most important achievement, which led to the discovery of the vitamins, developed from that phase of nutritional physiology which was briefly indicated above. He was the first to show that carbohydrate, fat, protein and inorganic salts, even when supplied in adequate amounts, do not suffice to maintain metabolic equilibrium. His experiments, planned on an extensive scale, we the first to be carried out with rats as experimen animals, and showed that other substances besid the above categories must be present in the food these, the accessory food factors, were later name vitamins as the result of a less happy suggestio by C. Funk.

It may be worth while to consider more closel this second period of nutritional physiology. There is scarcely a great scientific discovery which has emerged suddenly, without portent, from the brain of the investigator, as did Athene from the head of Zeus. As a rule, we become aware of forebodings, felt here or there, indications and observations, which create the atmosphere for the great discovery. That man does not live by bread alone—we may slightly vary the Biblical phrase—was already indicated more than fifty years ago (1881) by work from the Basle Physiological Institute. Lundin, a pupil of Gustav Bunge, was the first to show that mice could not be kept alive on a diet which had been compounded from the previously isolated constituents of milk, that is, from its carbohydrates, fats, proteins and inorganic salts. This important observation, which was confirmed ten years later by Socin, also working in Bunge's institute, was not followed by further research in the same direction. Impressed by the nutritional importance of inorganic salts, investigators were inclined to attribute the observed deficiency phenomena to a disturbance of the combination between these salts and the organic material, as a result of working up the milk.

In his Nobel Lecture, Hopkins acknowledges the merit of the Dutch physiologist Pekelharing in having attributed the nutritional insufficiency of the milk, thus separated into its main constituents, to the absence of unknown substances present also in other food materials; thus the vitamin concept was first clearly expressed. Pekelharing's paper, published in a somewhat inaccessible journal, only became known after vitamin research had already become extensive. The most important foundation for the development of such research was laid by the well-known work of Christian Eijkman on the causation of beriberi disease (1903). It was somewhere about this time that Hopkins began his investigations of the vitamin problem, investigations planned on an ample scale and based on clear theoretical conceptions. The great advance which they brought consisted in an experimental proof of the main idea, that the deficient nutrition resulting from the administration of the necessary calories, proteins and salts in the form of a 'synthetic' diet, is caused by the absence of factors necessary for life. Thus the concept of accessory nutritional factors was formulated by Hopkins, and so the vitamins became recognized as a new and indispensable group of foodstuffs.

Although Hopkins did not himself isolate any of the vitamins, of which he studied the effects—chiefly A and B—we are yet fully justified in regarding him as the spiritual father of vitamin chemistry. It was only by his clear physiological characterization of this group of substances that the field was prepared for the intervention of the analytical biochemist, to whom we now owe so extensive a knowledge of the vitamins hitherto isolated, knowledge gained in a remarkably short time. Closely connected with the study of the deficiency diseases due to the lack of vitamins, there are a number of similar investigations on the need for individual amino-acids formed in the hydrolysis of proteins. These researches Hopkins carried out by means of the same experimental methods; it might be said that they were ushered in by that chemical showpiece, the isolation and purification of tryptophane by means of its mercury compound. How important it is to have absolutely pure substances for physiological experiments is shown by the history of the discovery of vitamin D, which for a long time was identified as irradiated cholesterol, until Windaus and Rosenheim recognized that ergosterol was also present in apparently pure cholesterol preparations.

The work of P. Löwi and E. Abderhalden had shown that the mixture of amino-acids represented by artificially digested protein is just as suitable for nutrition as protein itself. By chemical methods it is possible to remove from the mixture one or other amino-acid, and Hopkins utilized this possibility to test the nutritional importance of individual constituents, by administering to animals the residue (together with non-nitrogenous foodstuffs) remaining in each case after removal of the amino-acid to be tested. The absence of the aliphatic amino-acids such as alanine, leucine and glutamic acid, does not adversely affect growth. If, however, tryptophane, or cystine, or histidine, or arginine has been removed from the mixture, a sharp decline in the weight of the animal is observed. These experiments give some idea of the synthetic powers of the mammalian organism, which is evidently able to build up the simple amino-acids, but fails in respect of the heterocylic. It has been suggested that histidine and arginine can replace one another mutually, and in that case the cell would be able to change arginine into histidine, a process which is not yet susceptible of chemical explanation. Likewise we have no understanding of the mechanism of the conversion of these amino-acids into nucleo-purines, which Hopkins' experiments rendered extremely probable.

Notwithstanding his preference for the biochemistry of protein and of other nitrogenous metabolites of the cell, Hopkins some thirty years ago made a singularly successful excursion into the field of carbohydrates. In conjunction with Walter Fletcher, he carried out a careful quantitative study of the formation of lactic acid in muscle. Conditions were discovered under which lactic acid is formed and again disappears; thus a solid foundation was laid for later and very successful work by others in this important field.

A few years after the end of the Great War, a generous benefaction enabled Hopkins to build a modern research institute at Cambridge, where he had occupied a chair of biochemistry since 1914. The group of workers who were collected here under his leadership developed in the course of a few years into a most successful centre of biochemical research, into a *universitas* of the discipline. A large number of young investigators—some with medical, some with chemical training, foreigners as well as natives—are at work there, almost exclusively in the field which we have described above as dynamic biochemistry. Many striving young biochemists, from all over the world, have sought instruction and stimulus in this important centre of research.

The close connexion between the investigation of vital processes and the analytical branch of biochemistry may be illustrated by reference to two natural products, both discovered at Cambridge, namely *glutathione* and *cytochrome*. The isolation of glutathione by Hopkins, a brilliant chemical achievement, brought in its train a very full programme of work in physiological chemistry, which occupied the Institute for several years. The history of the discovery of this tripeptide, composed of cysteine, glutamic acid and glycine, is characteristic. At first it was regarded as the dipeptide glutaminyl cysteine, until after a few years it was recognized that, by the original method of isolation, the glycine component was lost. A more delicate method of isolation then furnished the native product, which is actually present in most cells. Glutathione combines in its mode of reaction the role of hydrogen acceptor with that of hydrogen donator according to the scheme

$$2\ \mathrm{Gl{-}SH} \underset{+2H}{\overset{-2H}{\rightleftarrows}} \mathrm{Gl{-}S.S{-}Gl},$$

and is probably able, in consequence of this reversible function, to act as an intermediary in the chain of biochemical dehydrogenation processes. It is certain that it functions as an activator of animal proteases and of the enzyme methyl glyoxalase. Here there is doubtless a catalytic transference of hydrogen, in which process glutathione is probably concerned according to the equation:

$$\mathrm{CH_3.CO.CH(OH)_2 + Gl.S.S.Gl \rightarrow CH_3.CO.CO_2H + 2Gl\ SH}$$

$$\text{hydrate form of methyl glyoxal} \rightarrow \mathrm{CH_3\ CHOH.COOH + GlS.SGl}$$

Cytochrome is even much more closely concerned with the transference of hydrogen in intracellular oxidative processes.

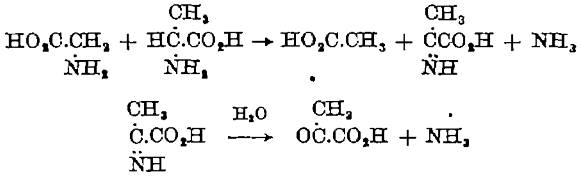
During the last fifteen years or thereabouts, research in the Institute under Hopkins' direction has been centred on vital oxidation processes. The purification of the dehydrogenating enzyme of milk (Schardinger's enzyme) and a study of its mode of action have occupied much attention. An important result has been the demonstration (by Dixon) that in the aerobic degradation of hypoxanthine and xanthine to uric acid by this enzyme, hydrogen peroxide is formed. Whilst on one hand the intermediate occurrence of hydrogen peroxide in cellular metabolism was thereby rendered probable, it was shown on the other (by Elliott) that peroxidative ferments also occur in the cell.

The principle of the hydrogen shift (dismutation), which governs the mechanism of alcoholic fermentation, has been carefully studied, especially in the metabolism of bacteria and other micro-organisms (by Quastel). The significance of intermolecular hydrogen transport in relation to the oxidative degradation of food material has already been mentioned in connexion with glutathione. The Institute at Cambridge has taken a prominent part in the modern development of the theory of vital oxidation, according to which hydrogen, the principal fuel of the cell, becomes combined with oxygen *via* several intermediate stages, not unlike a mountain torrent which finds its level over several waterfalls. The importance of this regulatory mechanism had already been pointed out by Hopkins in 1926 in his lecture to the International Physiological Congress at Stockholm.

The most important experimental result in this field was furnished by the work on cytochrome, which shows that this colouring matter, related to hæmin, possesses in its C-component the capacity to combine with the hydrogen of succinic and lactic acids when this hydrogen is activated by a specific dehydrogenase; then, again under the influence of an enzyme, the hydrogen is given up to molecular oxygen (Keilin, Green).

Succinic acid is dehydrogenated in this way to fumaric acid. With fumaric acid as hydrogen acceptor, *Bacterium coli* is liable to 'burn' *d*-glucose anærobically, as rapidly as in the presence of molecular oxygen (Krebs). Since the great power of fumarates (and, according to Krebs, also of pyruvates) to transfer hydrogen has also been demonstrated in animal tissues (Szent-Györgyi), we have already some insight into the chemical possibilities and the devious ways open to hydrogen when activated by enzymes either ærobically or anærobically.

Further light has been thrown on the biochemistry of hydrogen by the careful study of micro-organisms capable of using the element itself for purposes of hydrogenation or for the formation of water. These organisms may be contrasted with those which eliminate molecular hydrogen (Stephenson, Stickland). A particularly interesting example of this elimination, caused by the hitherto unknown enzyme hydrogenlyase, results in a novel transformation of amino-acids. Thus, for example, the hydrogen activated in the dehydrogenation of alanine is capable of splitting glycine into acetic acid and ammonia, according to the equation:



$$\underset{\dot{\mathrm{N}}\mathrm{H_2}}{\mathrm{HO_2C.CH_2}} + \overset{\mathrm{CH_3}}{\underset{\dot{\mathrm{N}}\mathrm{H_2}}{\mathrm{H\dot{C}.CO_2H}}} \rightarrow \mathrm{HO_2C.CH_3} + \overset{\mathrm{CH_3}}{\underset{\ddot{\mathrm{N}}\mathrm{H}}{\mathrm{\dot{C}CO_2H}}} + \mathrm{NH_3}$$

$$\overset{\mathrm{CH_3}}{\underset{\ddot{\mathrm{N}}\mathrm{H}}{\mathrm{\dot{C}.CO_2H}}} \xrightarrow{\mathrm{H_2O}} \overset{\mathrm{CH_3}}{\mathrm{O\dot{C}.CO_2H}} + \mathrm{NH_3}$$

There is scarcely a section of physiological chemistry which during the last fifteen years has not engaged the attention of the Cambridge Institute under Hopkins' direction. The output of papers, revealing the influence of the master in all directions, amounts to more than six hundred. In them we find vitamin studies continued in the direction of nutritional physiology, fundamental work on general, and especially on embryonic metabolism (Needham), and also papers on the virus problem (Pirie), to mention but a few of the principal topics.

This exemplary organization of research, which has brought the Cambridge School into the van of biochemical progress, has had a powerful influence on the development of the subject in all countries in which it is studied. In addition, the personal efforts of the leader, who on many occasions has insisted on the claims of biochemical studies and has pleaded for their intensive prosecution, have had an enduring effect on the status of the discipline.

H. WIELAND.

The Naming of Plants

The "Critica Botanica" of Linnæus

Translated by the late Sir Arthur Hort. Revised by Miss M. L. Green. (Ray Society Series, No. 124.) Pp. xxvii+239. (London: Bernard Quaritch, Ltd., 1938.) 12*s.* 6*d.*

THE publication of Sir Arthur Hort's scholarly translation of Linnæus's "Critica Botanica" is not only a very useful contribution to botanical science but also its appearance at the present time is singularly appropriate, since two hundred years have just elapsed since the Latin original was published in Leyden in 1737.

The late Sir Arthur Hort's manuscript was handed by Lady Hort to Sir Arthur Hill, who warmly recommended it to the Ray Society for publication, after it had been carefully checked and collated with the Latin text by Miss M. L. Green. She also translated the dedication to Dillenius, Sherardian professor of botany in the University of Oxford, for whom Linnæus entertained the highest esteem. Indeed he attributes to Dillenius some of the stimulus which encouraged him to undertake the task. "It was you", he says, "who, accustomed to weighing everything in the scales of sane reason and principle, opened to me the path, which albeit with hesitant steps I now seek to tread." Needless to say, there is no hesitancy to be found in the vigorous language in which Linnæus deals with the difficulties, which botanists were encountering at the time, owing to the absence of any rules governing the naming of plants.

In the "Critica Botanica", as the title-page indicates, the author examines the names of plants, generic, specific and varietal, retaining the better ones and rejecting the unworthy. This book forms part 4 of the "Fundamenta Botanica", which was published in the preceding year and constitutes the principles of botanical nomenclature. It is indeed the precursor of our modern international rules, which are discussed and amended at the successive International Congresses of Botany. That may suggest that the "Critica Botanica" will be dull reading. But this is far from being the case. Those interested in the history of botany will be delighted to find that it contains Linnæus's personal estimate of his botanical contemporaries and predecessors. The "Critica" may be usefully recommended to all students of botany and more particularly to those interested in systematic botany, as it will impress upon them the need there was in Linnæus's time for the adoption of the binomial nomenclature of plants, which he introduced and here defends. He also lays down the rules which should govern the choice of generic and specific names. But he is by no means dogmatic. "I submit the rules", he says, "which I have laid down for myself and in accordance with which I intend to walk. If they seem to you worthy, let them be used by you also; if not please propound something better."

In the first part of the volume, Linnæus deals with generic names, indicating those which he considers suitable for retention and those which should be rejected. Among these he includes particularly the hybrid words compounded from Greek and Latin roots, and he expresses his strong dislike of those formed by adding the suffix -oides to an existing generic name. He prefers those which have a Greek root and is antipathetic to compound words, though he is prepared to retain some like *Sempervivum* and *Saxifraga*. He rejects as generic names those of saints and miscellaneous public characters but retains those taken from mythology and the consecrated names of kings. He has a particularly soft spot for the names given to preserve the memory of botanists who have deserved well of science. After describing how kings and emperors and many brave and gallant men have wished their names to be handed down to posterity, he adds:

> "Why should it not be the same with botanists, whose venture has been quite as daring? What toils, what science would be more wearisome and painful than botany, did not some singular spell of desire, which I myself cannot define, often hurry us into this pursuit. Good God! When I observe the fate of botanists, upon my word, I doubt whether to call them sane or mad in their devotion to plants. I will adduce some instances."

Then he gives particulars of his own journeys and privations and those of other well-known botanists.

In this way, the lists of generic names and his critical remarks on the same are interspersed with entertaining passages and good-humoured remarks about botanists and would-be botanists. Thus our perusal of the "Critica" reveals Linnæus not only as the constructive systematist but we also get a glimpse of the man himself, with that twinkle in his eye which his portraits reproduce.

The second part of the volume dealing with the specific names of plants is equally interesting. The specific name, according to Linnæus, should sum up in one word the chief diagnostic character of the species and should not be descriptive of the locality in which the plant is found nor embody the name of the discoverer. Still less should it consist of a trope or metaphor such as melancholy or humble. But it is essential to read through this part of the book to realize how many specific names are really inappropriate. We also gain an insight into the methodical simplification introduced by Linnæus in comparison with the string of adjectives used by many of his predecessors in naming plants.

We close the book with feelings of respect and gratitude touched with affection for the author, with profound thanks to the translator and with due appreciation of the labours of all those who have lent their assistance to the production of this volume.

From Science to Fantasy

Horizons of Immortality:
a Quest for Reality. By Erik Palmstierna. Pp. viii+366. (London: Constable and Co., Ltd., 1937.) 10*s*. net.

TO those who view with some disquietude the changing attitude of the modern temper with regard to science, this book will come with no surprise. It would seem that there is an increasing tendency among the public to demand of science what it never sets out to give, and then to blame it for giving stones where bread is craved. The aim of the scientific worker is not to provide consolation and spiritual certainty for distressed souls: it is to try to enlarge the extent of human experience and to bring it into some kind of orderly sequence.

The general drift of human thought to-day cannot be said to be wholly or even partially satisfying to many people whose type of mental activity leads rather to artistic or mystical expression than to scientific effort. For in these days much of science itself seems unintelligible; and the paradoxes of physics and the principle of indeterminism are not helpful to those who desire absolute certainty both here and hereafter. Hence the retreat into fantasy is to be understood even if it is to be deplored.

The substance of the volume under notice consists of 'messages' spelt out by the familiar method of the glass and letters. The greater part of the material has been obtained through the instrumentality of the violinist Adila Fachiri, but the earliest messages were received by her sister, Miss Jelly d'Arànyi, and a friend.

The general purport of the messages, which claim to proceed from spirits, and as such are accepted by the author of the book, is of a kind familiar to students of automatisms, and consists of spiritual advice, information and religious teaching. What is, however, of considerable interest, showing the tendency of the flight from science, is the insistence throughout the messages on the necessity for faith, and contempt for anything savouring of curiosity and intellectual criticism. "What we object to and definitely repulse," one message reads, "is curiosity and the wish to explain everything through and with your perishable brain. It is in every case a drifting again from the Great One, ergo renewed sinnings and why, because you do not want to admit nor allow that only God knows everything", etc.

Although Baron Palmstierna and the automatists apparently accept these very unevidential messages at their face value, it would seem that they suspect that the public would like something better, and thus at the end of the book occur a few cases inserted to suggest that some form of supernormal activity is clearly to be seen. Were it not for one of these cases, that of the Schumann Concerto, popularized by the British Broadcasting Corporation, it is possible that the book would have received no more attention than any other collection of automatic scripts.

It appears that in March or April 1933 Miss Jelly d'Arànyi was receiving messages by the glass and letters when Robert Schumann professed to communicate. A posthumous work of his for the violin was mentioned and some hope was expressed that Miss d'Arànyi would find and play it. At the time, Miss d'Arànyi did not remember any such work and inquiries failed to locate it. Finally, after a number of messages insisting on the search had been received, but without revealing the location, the manuscripts were found to have been deposited in the Prussian State Library, where they were duly preserved. The facts were quite simple and there was no mystery about them, but they were treated as spiritualistic propaganda and it was asserted that a long-lost manuscript had been located by psychic means, whereas the truth was that it had been acquired by the Prussian State

Library and was preserved there along with hundreds of other manuscripts. It is true that the place of preservation may not have been generally known, but this place was never revealed by the messages, excuses always being offered when the question was asked. Now, assuming the non-psychic nature of the material, how was it that Miss Jelly d'Arànyi's mind was directed in March or April 1933 to Schumann and his unpublished manuscripts ?

In assessing the value of automatic productions, one of the main difficulties is to discover the sources of the information given. How can we trace the association of ideas when the life of the automatists is so complicated and open to so many influences ? Very often it is clearly impossible, but in the present instance two factors may be thought to have been relevant. In February 1933 the popular cheap edition of Bedford's "Robert Schumann" was published, which was originally issued in 1925 in the "Masters of Music" series. In this work the unpublished concerto was mentioned. Now in March of the same year it was announced in Great Britain that six new Schumann polonaises had been discovered in the archives of the Vienna Gesellschaft der Musikfreunde. Further, in Moser's "Joseph Joachim", where the concerto is also mentioned, we are told that the last movement "is written as a polonaise in three-quarter time". Since Miss Jelly d'Arànyi is related to Joachim, we may presume that at one time she may have looked at Moser's book, and the news of the discovery of the six unpublished polonaises in Vienna may have been the trigger which set the automatism in motion, or at least it may be regarded as the kind of mechanism which we should expect when searching for the origin of such subliminal activity.

Baron Palmstierna attempts to discredit the evidence for the theory of subconscious mental processes in *Bulletin* 4 of the International Institute for Psychical Research Ltd. (London, 1937), although his arguments can scarcely be called convincing. Space is lacking to discuss these, but it may be said that the author is of such transparent honesty and sincerity that efforts to shake his conviction are not likely to succeed. It is clear that a critical analysis of the messages is not desired, for in them he thinks that many would say that "we are near the State which Saints and Mystics call the Communion of Saints". Whatever we may think of the flight from science into fantasy, it is clearly satisfying to those who have undertaken it.

The Soviet Polar Station

On the Top of the World:
The Soviet Expedition to the North Pole, 1937. By L. Brontman. Edited by Academician O. J. Schmidt. Pp. 287 + 25 plates. (London: Victor Gollancz, Ltd., 1938.) 16*s*. net.

THE acclaim which greets a polar expedition is too often measured by the accidents with which it has been beset, and nothing gives greater popularity than disaster. But the Soviet expedition to the North Pole gained no fame on these grounds. It was the sheer audacity of the venture that brought it to notice. The use of aeroplanes in polar exploration was not new ; many daring and successful flights had already been made in both arctic and antarctic regions. But so far no party of explorers had voluntarily submitted to living on the floating pack-ice with no obvious line of retreat. Here was no hurried journey across the sea-ice, but a stay of uncertain duration on a floe of uncertain stability and unknown destination. It was not, however, a reckless project, for certain movements of the arctic pack were known and could be anticipated, and aeroplanes and ice-breakers were all the time held in readiness for the rescue.

The book under notice gives an account of the preparations and equipment of the expedition by one of the Moscow newspaper correspondents who was present at its start in the vicinity of the Pole. The scheme was part of the widely planned exploration and development of Soviet Arctic territory, although by a touch of irony the entire course of the floe was outside the Soviet sphere. An advanced flying base was chosen on Rudolf Island, one of the Franz Josef Islands in lat. 81° 50′ N. Thither an icebreaker and another steamer carried supplies and material for a station, and when all was ready, five aeroplanes set out from Moscow and, after a relatively uneventful journey via Novaya Zemlya, reached the base on April 19. There the aeroplanes were refuelled and overhauled and after a reconnaissance flight and a wait on account of bad weather, the Pole was reached on May 26 and the work of the observatory began.

There was abundant food, carefully chosen. Clothing and tents were well designed and scientific equipment was admirable. In a few days the aeroplanes returned to Europe and left the four men to their own resources.

The book is full of detail up to this time and recounts also the return flight. Then follow some of the wireless messages sent out for two months and there the book ends, for it was compiled too early to record the last months of precarious drift, the prospective dangers off the Greenland coast and the rescue in the depths of the Arctic winter. No striking discoveries were made or indeed expected: the Arctic has yielded its chief secrets. The thrills of flying abound in every chapter, but the speed of air transport has robbed the polar narrative of its sustained interest and tended to make it solely a record of mechanical triumph.

Beyond this, two aspects of the expedition are notable. One is the extraordinary efficiency of the organization and equipment: everything worked to plan; nothing went amiss; no life nor aeroplane was lost. The other feature is the boundless enthusiasm of all who participated in the venture. One expects polar explorers to have enthusiasm for their work, but few have so persistently recorded their feelings of enthusiasm and devotion to their national ideals. There is no criticism of plan, equipment or accomplishment: an endless song of praise and congratulation permeates the book, but there is little laughter or high spirits. The valuable scientific results receive little attention, as might be expected in a book written before the expedition had ended.

However, the new methods of polar technique which flying has introduced are well expounded, and there are useful lists of equipment, stores and instruments. Not the least interesting chapter gives the biographies of the four men. All had considerable previous polar experience and all had that longing for polar regions that once acquired is so hard to overcome. There are many excellent illustrations and two adequate maps.

R. N. RUDMOSE BROWN.

Economists Arraigned

Lament for Economics

By Barbara Wootton. Pp. 322. (London: George Allen and Unwin, Ltd., 1938.) 6*s*. net.

THE indictment is that "the economic theory of to-day is useless because it is unintelligible; because, after all their arduous studies, the economists cannot be relied upon not to give diametrically opposite diagnoses and prognoses of the same situation . . . ; because the economists feed on their own tails by busying themselves with the analysis of imaginary worlds which they themselves have invented; and because they are passing off as the result of purely scientific inquiry what is in reality no more than a partisan advocacy of particular social policies".

The charge of unintelligibility having been dismissed, in Chapter ii the author examines "the relation of economic theory to the actual world", and the question why economic theory has not contributed more than it has to the solution of practical economic problems. The next two chapters discuss the claim of economics to be a science, and the accusation that economics is mere apologetics for contemporary institutions. Chapter v considers how far market equilibrium correctly interprets the optimum distribution of resources, and finally, in the light of all these discussions, the author puts forward her views as to the lines along which economics should be developed in the future.

It must now be stated that the writer of this review is one of "the economists" as defined by Mrs. Wootton. Having made every effort to overcome the resulting bias, I cannot persuade myself that this is a very useful book or one worthy of its author. The trouble is that it attempts to combine (1) an apologia to the man in the street on behalf of economics and "the economists", (2) an attack on "the economists" and on one economist in particular, who incidentally will probably be astounded to find himself deemed so representative of the general thought of economists to-day, and (3) proposals which, however admirable in themselves, are not exactly novel and do not seem to have much logical connexion with the preceding chapters. The result is that this book is neither a deadly attack on "the economists" nor a serious contribution to the future development of economics. Most, if not all, economists will find many pages and some conclusions with which they can heartily agree and much with which they will disagree, but they will find little of which they are not perfectly well aware. The general reader may gain a better knowledge of much of which he is imperfectly aware, but at the end his ideas as to "the economists", their aims and the sort of work they do will probably be even more curious and less exact than they are at present. Even the general lines of the proposals in the concluding chapter can be and have been argued more forcibly on very different premises.

As Mrs. Wootton knows, and in part admits, self-satisfaction is not a besetting sin of "the economists", and many fully share her troubles and sorrows. But this book seems to have been written in something very like mere exasperation, and, however pardonable, exasperation is not conducive to well-balanced and constructive thought or to enlightened vision.

J. W. F. ROWE.

Tables Annuelles Internationales de Constantes et Données numériques:

International Annual Tables of Constants and Numerical Data. Vol. 11 (Years 1931–1934.) Part 1 (Sections 1–25). Pp. xvi+492+xv–xxv. (Paris: Hermann et Cie.; New York: McGraw-Hill Book Co., Inc., 1937.)

These sections contain very complete numerical data on molecular spectra of diatomic and of polyatomic molecules. In addition, the derived quantities—electronic levels, fundamental vibration frequencies, anharmonic coefficients, moments of inertia, atomic distances, linkage force constants, and dissociation energies—are presented in an accessible and systematic way, and many of the relationships explained by potential energy curves. The tables will prove invaluable to both physicists and chemists interested in the problems of molecular structure, and the simplicity of the arrangement will give confidence to those who may hesitate before attempting to seek the solution to a query in the complexities of the original literature. To the critical survey of molecular spectra is appended a bibliography and element-index of the numerous papers on atomic spectra which have appeared in the period 1931–34.

Peter Kürten:

a Study in Sadism. By George Godwin. Pp. 60. (London: The Acorn Press, 1938.) 5s. net.

In "Peter Kürten", George Godwin has given us an account of one of the most horrible series of crimes in history. Peter Kürten, who was a sadist of the worst type, kept Düsseldorf in a state of terror. His record of crime went back to his childhood, when he pushed two boy friends off a raft on the river and drowned them. When tried, he was charged with ten murders and convicted of nine of them. The medico-legal experts came to the conclusion that the Dusseldorf 'monster' was suffering from no organic mental disease or from any functional mental disease, and was therefore responsible in law for his crimes.

Reading, Writing and Speech Problems in Children:

a Presentation of Certain Types of Disorders in the Development of the Language Faculty. By Prof. Samuel Torrey Orton. (Thomas W. Salmon Memorial Lectures.) Pp. 215. (London: Chapman and Hall, Ltd., 1937.) 10s. 6d. net.

This book contains the third of the Thomas W. Salmon Memorial Lectures. The writer gives an account of his well-known work on disorders of the language faculty in children. He discusses the various disorders of language found in the adult as a basis for considering the language disorders of children. The work is based on his very wide clinical experience of ten years, combined with pathological material. He also gives the results of therapeutic efforts based on this work, and shows that many children with speech defects have derived benefit. The work is a most valuable addition to our knowledge of speech defects not only in children but also in adults.

An Elementary Treatise on Statically Indeterminate Stresses

By Prof. J. I. Parcel and Prof. G. A. Maney. Second edition. Pp. xvi+432. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 25s. net.

The continuous attack made during recent years on the problems of indeterminate structures and the heavy labours involved in all rational computations of such types necessitate the careful study of the scope and function of different methods, with a view to effective selection. The first edition of this book was finely characterized by a well-balanced consideration of the various methods of attack, and this second edition incorporates extensions that include the new and useful Cross method, and special adaptations of the slope deflection method. The re-written chapter on rigid frames includes a good treatment of the multi-storied building, but does not refer to the work of the British Steel Structures Research Committee. All illustrative examples are worked with great clearness, and in its scope and arrangement the book is excellently designed for the student who intends to use structural theory.

Plato's Conception of Philosophy

By Dr. H. Gauss. Pp. xxii+272. (London: Macmillan and Co., Ltd., 1937.) 6s. net.

The author of this ably written book is right in considering philosophy less as a body of results than as a mode of life. Owing probably to his wish to defend this conception, he restricts his inquiry into Plato's doctrines to his attitude towards epistomology, ethics and life in general. On these points Dr. Gauss has many useful suggestions to make which may serve to complete the traditional interpretation of Plato that has become part of British philosophy. Besides the scholarly interest of this work, to which Prof. Taylor contributes a striking preface, there is an attempt to show that philosophy is not a purely academic pursuit. The success of this plea will depend in large measure on the use of the author's method for the interpretation of other aspects of philosophy and of its history.

T. G.

The Definition of Psychology:

an Introduction to Psychological Systems. By Dr. Fred S. Keller. (Century Psychology Series.) Pp. viii+111. (New York and London: D. Appleton-Century Co., Inc., 1937.) 4s. 6d. net.

This volume gives a very good account of the growth of the conception of psychology through the years, from the early days through the work of Titchener and up to the most recent work of the behaviourists and finally the *Gestalt* school. Psychology is becoming more objective and standing more on its own feet with less dependence on physiology. It is more genetic and comparative, and occupies itself more with individual differences, and with abnormal psychology. There is a strong flavour of behaviourism about the author's views, tinged with a respect for the *Gestalt* school.

The Concept of Species in Biology

THE one hundredth and fiftieth anniversary meeting of the Linnean Society of London took place on May 24, when the presidential address was delivered by Dr. John Ramsbottom, and on the two following days symposia were held in which a number of distinguished British and foreign zoologists and botanists took part. The meetings, which were attended by a large concourse of fellows and foreign members of the Society and by delegates from many cognate societies and institutions in Great Britain and overseas, were held in the lecture theatre of the Royal Institution and were planned to provide for a discussion of the various aspects of the 'species problem' in biology. The address of the president dealt with "Linnæus and the Species Concept" and the subjects of the two symposia were, respectively, "The Concept of Species from Linnæus to the Present Day" and "Geographical Isolation as a Factor in Species Formation".

LINNÆUS'S CONCEPT OF SPECIES

In his address, Dr. Ramsbottom pointed out that, in studying the works of Linnæus, it must not be assumed that his opinions remained unchanged throughout the whole of his career, from his first book in 1737 to his last in 1767; incidental observations must be interpreted in their relation to the particular subject under discussion; and we must guard against reading into some isolated sentence the germ of a theory formulated at a later date. The doctrine of the fixity of species, so far as it was accepted by the predecessors and contemporaries of Linnæus, was a deduction from the Mosaic account of the Creation, an account which some at least of the early Fathers of the Church did not accept as conveying scientific as distinguished from moral and spiritual truth. The doctrine was enunciated by Linnæus in an often-quoted passage in his "Philosophia Botanica" in 1751: "Of species of plants we reckon so many as there were different forms created in the beginning by the Infinite Being; and these forms, according to the appointed laws of generation, have always produced offspring like themselves."

It is clear, however, that even when this categorical statement was printed, Linnæus had some mental reservations and qualifications. He was already engaged upon his "Species Plantarum", published two years later. Scattered through this work are passages difficult to reconcile with the dogmatism of the "Philosophia". For example, under *Rosa indica* he writes: "The species of *Rosa* are difficult to distinguish and more difficult to determine; it seems to me that Nature has intermingled several or in sport formed several from one". After describing four species of *Scorpiurus* he adds, "It is beyond doubt that all these formerly arose from a single species", and of certain species of *Geranium* he says, "The flower and habit of the last three species show that at the beginning they were one". In this respect, evidently, his didactic aphorisms lagged behind his practice.

So early as 1744 Linnæus had discussed the possibility that new species of plants might arise by hybridization, and in the later years of his life he gave much attention to this subject. Dr. Ramsbottom quoted many passages on this subject. Perhaps the most striking was from a work published in 1761 where, after discussing such possibilities as that "a genus is nothing else than a number of plants sprung from the same mother by different fathers", Linnæus concludes, "But whether all these species be the offspring of time, whether in the beginning of all things the Creator limited the number of future species, I dare not presume to determine".

In the light of these and many other passages, Sachs's assertion that Linnæus "held fast to the end of his life" to the dogma of the fixity of species is simply untrue.

For a century after Linnæus, botanists and zoologists were hard at work accumulating and naming collections. The Linnæan systems of classification and nomenclature afforded, to the botanists at least, the only hope of grappling effectively with the rapidly growing masses of material. They dreaded the confusion that would result if these were interfered with. Hence the vehement opposition that was at first offered to attempts to introduce a natural system of classification; hence, also, the tradition that Linnæus was an inflexible upholder of the permanence of species.

DEVELOPMENT OF SPECIES CONCEPT

In the two symposia on May 25 and 26 a large number of speakers took part either by reading papers or in the course of the subsequent discussion.

Space does not permit of our giving more than brief summaries of a few of the papers, and the following must not be taken to represent more than the impressions of one member of the audience. A full report will appear in due course in the *Proceedings* of the Society.

The first symposium was opened by Sir Edward Poulton, who said that, in his opinion, a species must be regarded primarily as an interbreeding or syngamic community. Proof of this syngamy is often difficult to obtain and long delayed, but it is conclusive and brings release from the need for regarding the species as merely an artificial grouping for purposes of convenience. Continuity or transition of characters between two groups is held to prove that one is a variety of the other, discontinuity that they are distinct species. Discontinuity, however, is not enough, as is shown in the case of polymorphic species. The splendid collections bequeathed to the nation by the late Lord Rothschild bring into prominence the conception of sub-specific groups fused by syngamy into single species but ever ready, by preferential mating or the effects of isolation, to break up into separate species.

Prof. E. W. MacBride said that since Darwin's time it has been shown that the minute variations on which he rested his case were not inherited. Mutations, on which the whole of modern genetics depends, are characterized by a loss of viability as compared with the type, and can never have survived in the wild state. The cytological basis of genetics is unstable and some of its assumptions are demonstrably false. There remain only acquired habits, asserted by Lamarck in 1809 to be the cause of the differentiation of species, and this has now been experimentally proved.

Prof. Ö. Winge (Copenhagen) while regarding the genetic nature of specific differences as beyond discussion, said that it is often difficult to decide in any given case how many genes are involved and whether the cytoplasm, as well as the nucleus, plays a part in the inheritance of such differences. It was discussed whether the differences between species, genera, families, etc., are of a special nature, and three possibilities were considered; (1) that the taxonomically important genes are polymerically present in several or all of the chromosomes; (2) that "vital genes" (the alleles to "lethal genes") are of particular taxonomic significance; and (3) that the genes in question are stable, non-mutable, and hence escape our analysis.

Sir Arthur Smith Woodward said that our increasing knowledge of extinct animals is making the use of the Linnæan method of classification very difficult. Instead of classes, orders, families and genera, the palæontologist is concerned with phyla, lineages, branches and grades. Related lineages pass through the same orderly succession of changes, by which the same—or nearly the same—result is eventually obtained. Examples of parallel evolution and polyphyly were described in Graptolites, Elasmobranchs and Holostean fishes, and others were mentioned in reptiles, birds and mammals. Sir Arthur considers, however, that it is premature to attempt to introduce new principles for naming species, genera and families, and that it is convenient to retain the old system as a provisional expedient until we are more sure of our facts.

Dr. Karl Jordan (Tring Museum) pointed out that, although geographical variations were known at the time when the Linnean Society was founded, the fact that the area of most species is subdivided into smaller areas each populated by a subspecies is a comparatively modern discovery the significance of which is not generally grasped by biologists. The subspecies are the real units on which research in systematics is based, and he emphasized the importance for research of large collections like those in the Tring Museum brought together with this end in view.

Other speakers who took part in this symposium were Dr. E. Stensiö (Stockholm), Prof. H. J. Lam (Leyden), Prof. M. J. Sirks (Groningen), Prof. H. Boschma (Leyden), Prof. B. Němec (Prague) and Prof. W. Robyns (Brussels).

GEOGRAPHICAL ISOLATION AND SPECIES FORMATION

The subject of the second symposium was introduced by an address by Dr. Julian Huxley, summarizing the present state of knowledge on geographical differentiation. He said that species inhabiting large but continuous areas tend to show gradations of character from one part of their range to another. For these continuous graded changes he has introduced the term "phenocline". Gaps may be produced in this continuity by obstacles to interbreeding, spatial (topographical), ecological, genetical, physiological, or psychological. Subspecies might thus be produced by segregation of non-adaptive mutations or by the beginnings of adaptive radiation.

Prof. P. A. Buxton spoke on the insect fauna of oceanic islands. He said that although the fauna and flora of such islands are impoverished it must not be assumed that competition is therefore less severe. In the absence of many predatory groups of animals the struggle for existence may be less hard and there may be more freedom of evolution. This would explain the extreme variability of some species of insects (of which examples were described) and the formation of "endemic complexes" of closely related species.

It is less easy to account for the appearance of many monotypic endemic genera.

Dr. E. Fischer-Piette (Paris) gave an account of his work on the limpets of the North Atlantic. These form a complex capable of splitting into several species. This splitting is realized, morphologically and ecologically, in certain districts of the coastline, but not in others. In these last districts there is much variation, leading to unaccustomed types each special to a locality. Geographical isolation is not necessary for the formation of new species of limpets, although their formation is greatly favoured by it.

Dr. Bernard Rensch (Münster) opposed the view put forward by Goldschmidt, among others, that the transformation of species is governed by special laws, whereas geographical races only result from a secondary splitting up of species. He considers that geographical isolation of large populations is the first step not only towards new races but also towards new species, and that such a differentiation gives rise also to the higher systematic categories The separation of new species by isolation from race-complexes (*Rassenkreise*) is the chief method of evolution. Examples of other methods are not numerous. Sometimes ecological isolation has been at work and, more rarely, a dominant mutation arises and spreads until it replaces the original form. In other cases, selection by external factors, especially climatic ones, is evident, leading to parallelism among geographical races. Prof. Karl Skottsberg discussed the flora of the Juan Fernandez group of islands and of the Hawaiian group.

In both symposia, more especially the first, the various speakers approached the problem of the nature and origin of species from very diverse points of view—systematic, palæontological, ecological, genetic, cytological. There resulted a certain appearance of discontinuity in the discussion, which, as one of the speakers remarked, emphasized the desirability of combined and detailed exploration of the field towards which all these lines of research converge. For such exploration, no more fitting place could be found than the Linnean Society.

Molecular Migration under the Influence of Centrifugal, Osmotic and Electric Forces*

OUR knowledge of the mass movements of large molecules in various fields of force has its foundation in the early researches of Svedberg, and consists in large part in contributions from the Uppsala School. Since the occasion of Svedberg's recent lectures at Oxford†, further improvements in experimental technique have been made, and the scope of these physical investigations, particularly where they touch on biological problems, has been greatly enlarged.

Studies of the resolving power of centrifuge rotors reveal that, in general, rotors of large diameter rotating at low speeds are preferable to smaller rotors at higher speeds. The resolving power is slightly higher and greater accuracy of optical observation is possible with the larger rotors. For rotor construction, steel is still to be preferred to light metal alloys, in spite of the greater ratio of strength to density offered by the newer aircraft alloys. This is due to the fact that around the cell holes, about one half of the total stress arises from the outward thrust of the cell, and the cell weight in modern constructions is reduced to a minimum. By reducing the bearing diameter from 18 mm. to 10 mm., the power dissipated in bearing friction has been reduced to some 300 watts at 60,000 revolutions per minute, or about one seventh of the earlier value. Rotors with such low bearing friction take an inconveniently long time to come to rest, and to reduce this time a magnetic brake system has been introduced. In spite of the much lower frictional losses in the air turbine ultracentrifuge, the energy required to drive this type is now actually greater than in the case of the oil turbine machine, owing mainly to the much lower efficiency of the air turbines. A new type of divided centrifuge cell, the inner chamber of which is made from the British transparent plastic 'Perspex', is available which enables the observation and separation in substance of ultracentrifuge fractions at the end of an experiment.

The study of molecular migrations in the electric field has been facilitated by the development of an improved electrophoresis apparatus by Tiselius in Svedberg's laboratory. It is possible with this apparatus to observe the migration of the components of a mixture and to isolate these for subsequent chemical or biological investigation.

---

* An account of three lectures delivered by Prof The Svedberg, of Uppsala, at University College, London, on April 29, May 2 and 3.

† Summarized in a supplement to NATURE of June 19, 1937

By application of the methods of sedimentation, osmotic and electrophoretic analysis to many naturally occurring substances, much valuable information has been obtained, and certain general conclusions may be drawn regarding the molecular state of substances in Nature. Of the proteins it may be said that Nature prefers to manufacture these in a homogeneous form, that is, with molecules all of the same size. Good examples of homogeneous proteins are the albumin of the hen's egg, the crystalline globulin of milk, and the coloured respiratory proteins. A protein is only homogeneous within certain limits of hydrogen ion concentration of its solution. Outside these limits, associations and dissociations of the molecules take place. In the case of the hæmocyanin pigment from the snail *Helix pomatia*, for example, dissociation of the large parent molecule occurs into fragments of one half, one eighth and one sixteenth of the molecular weight of the original. Numerous other factors cause similar step-wise degradation of protein molecules, the changes being often of an irreversible nature. Of special interest is a form of specific degradation which is, however, reversible. It appears that in a mixture of proteins the larger molecules are frequently split up by the influence of the smaller molecules. Blood serum affords an important illustration of this, the concentration of smaller molecules in the undiluted serum being increased markedly by dissociation of the larger globulin molecules into fragments of the approximate weight of serum albumin, namely, 69,000. It is not possible to give a complete explanation of this phenomenon, which must be of great importance in the living organism.

Proteins which are homogeneous in the centrifuge are frequently also homogeneous in the electrophoresis apparatus. A notable exception is the globulin of blood serum, the molecules of which are approximately uniform in size with a weight in the neighbourhood of 160,000. In the electric field these molecules separate into three distinct groups of different mobilities. Tiselius has been able to isolate these globulins and to characterize them as protein entities.

Various diseases alter the state of the serum proteins, and it is well known that in the majority of cases the alteration affects only the globulin part of the serum. These new methods show that in the serum obtained by immunizing the rabbit with egg albumin, only one of the three normal globulins is increased. Separation of this globulin results in a considerable concentration of specifically precipitable protein. Immunization of the rabbit with type III pneumococcus results in the appearance of a new serum protein with the same molecular weight as the normal rabbit globulins but electrochemically different from these. On absorption of the serum with the type specific carbohydrate, this new fraction can be removed quantitatively from the electrophoresis photograph. On the other hand, immunization of the horse with type I pneumococcus produces a fraction which is different both in respect of molecular weight and electrophoretic mobility from the normal globulins. These and other phenomena demonstrate that the changes in the serum proteins which accompany the development of immunity are of a diverse nature and are not at the moment amenable to any simple explanation.

In the important field of the respiratory proteins, cytochrome *C* and myoglobin have been found to have the same molecular weight, namely 17,000, or approximately one fourth of the weight of hæmoglobin. The yellow enzyme, on the other hand, has a molecular weight of 80,000 and one prosthetic group in the molecule. All the enzymes so far isolated in a pure state have been proved to be proteins. Pepsin is a well-defined protein of molecular weight 37,000. The catalase molecule has recently been shown to contain four atoms of iron in the molecule, like hæmoglobin, but to have a molecular weight approximately four times as great, namely, 248,000. The largest enzyme molecule so far measured is that of crystalline urease, which has a weight of 483,000.

In recent years, more attention has been devoted to systems containing linear macromolecules. This field includes the carbohydrates, particularly cellulose, starch and glycogen; synthetic polymers such as the polystyrenes; and hydrocarbons such as rubber. In general these systems are far from homogeneous, the chain length varying from one molecule to another. The main object of study, therefore, is the size-distribution curve, which is best obtained from measurements of sedimentation velocity. Suitable solvents are often difficult to find, and the interpretation of the results is complicated by the asymmetry of the molecules, by the interactions of neighbouring molecules, and by solvation. The molecular state of starch is much influenced by the past history of the preparation. Acid-treated solutions show an amylose fraction of mean molecular weight about 60,000 and an amylo pectin of approximately 200,000; both are polydisperse. Glycogen and its methylated derivatives are highly polymerized, and also polydisperse. The specific polysaccharide of type I pneumococcus is polydisperse with an average weight of approximately 225,000. Recently, however, a homogeneous polysaccharide of low molecular weight, namely, 9,000, has been isolated by Dr. Florence Seibert from filtrates of tubercle bacillus cultures.

A. S. McFarlane.

News and Views

Sir D'Arcy Thompson, C.B., F.R.S.

At the anniversary meeting of the Linnean Society held on May 24, the Linnean Gold Medal was presented to Sir D'Arcy Wentworth Thompson. In handing the medal to him, Dr. J. Ramsbottom, the president, said: "Since its foundation, the Linnean Society, while maintaining the traditions associated with the great Swedish naturalist whose name it bears, has always welcomed to its fellowship the disciples of the newer schools whose studies of the organic world have led them into fields of knowledge Linnæus never knew. It seemed to our Council, therefore, especially fitting that on this, our one hundred and fiftieth anniversary meeting, the highest honour in our gift should be conferred on a naturalist who, more than any other of our time, has shown himself to be at home in both the fields of the old and of the newer learning. The founders of our Society were, most of them, classical scholars as well as men of science, and we can well imagine Bishop Goodenough and Sir James Edward Smith exchanging snuff-boxes while they discussed and approved the ripe scholarship of your 'Glossary of Greek Birds' and your translation of Aristotle's 'Historia Animalium'. But, if these works are in the eighteenth century tradition, your 'Growth and Form' is no less distinctively in that of the twentieth. Published in war-time, it was one of the first scientific books some of us read when we came back to civil and scientific life in 1919. It is already something of a classic on the shelves of the younger biologists of the experimental school, and we turn to it again and again, not only for information but for inspiration and delight. In selecting you, sir, as the recipient of the Linnean medal, we have no doubt that our choice is one that would have pleased Linnæus himself."

Cases of the Linnæan Collections

During the Great War, the herbarium formed by Linnæus and now in the possession of the Linnean Society of London, was removed from the three wooden cases which had contained it since the time of Linnæus and placed for greater safety in steel cabinets. The Council of the Society recently decided that the one hundred and fiftieth anniversary of the Society would be a fitting occasion for returning two of the cases to their original home by presenting one to the Swedish Linnean Society and one to the Linnæus Museum at Hammarby. At the anniversary meeting of May 24, the keys of the cases were handed by the president to Prof. Robert Fries, president of the Swedish Linnean Society. Prof. Fries, in expressing thanks for the gift, said that all Swedish naturalists are grateful to the Linnean Society of London for the great care it has always taken of the priceless treasures in its custody.

Prof. R. H. Fowler, F.R.S.

The Lord President of the Council has appointed Prof. R. H. Fowler to be director of the National Physical Laboratory with effect as from October 1 next, in succession to Dr. W. H. Bragg, who has been elected to the Cavendish professorship of experimental physics in the University of Cambridge. Prof. Fowler, who is now forty-nine years of age, has had a brilliant career at Cambridge. So long ago as 1914 he was elected a fellow of Trinity College, and he received the Adams Prize in 1925 for an essay on "The Physical State of Matter at High Temperature". In 1932 he was appointed to one of the John Humphrey Plummer professorships established at Cambridge in the previous year, namely, that of mathematical physics. His election to the Royal Society came in 1925, and he was awarded one of the Society's Royal Medals in 1936. Prof. Fowler's scientific work includes the development of a general theory of statistical mechanics, with applications of outstanding importance to the equilibrium of mixed crystals and to the theory of semi-conductors. His work on the photo-electric effect led to a means of determining the true threshold frequencies. He has also developed new aspects of the quantum theory of energy exchange between gases and solids. Finally, by his application of the developing quantum theory to the solution of problems under investigation by groups of experimental physicists working in close association with him at Cambridge, he has made contributions of fundamental importance to both theoretical and practical physics.

Sir Thomas Middleton, K.C.I.E., F.R.S.

The Committee of the Privy Council for the Organization and Development of Agricultural Research, after consultation with the members of the Agricultural Research Council and the president of the Royal Society, has appointed Sir Thomas H. Middleton to be chairman of the Agricultural Research Council as from July 1. On that date the Right Hon. Lord Richard Cavendish, who has been chairman of the Council since its inception in June 1931, retires from membership of the Council. Sir Thomas Middleton, who is vice-chairman of the Development Commission, an office which he has held since 1929, has been a member of the Agricultural Research Council since its establishment. He is chairman of one Standing Committee of the Council on Soils and Plant Nutrition and of the Committee on the Estimates of Research Institutions. Sir Thomas has been successively professor of agriculture in Baroda College, India, lecturer in agriculture in the University College of Wales, Aberystwyth, professor of agriculture in Durham College of Science, and professor of agriculture at Cambridge. In 1906 he joined the staff of the Board of Agriculture and

Fisheries as assistant secretary, and in 1917–19 was deputy director-general of the Food Production Department. He was a member of the Royal Commission on Agriculture in India, which sat in 1926–28. He was the first recipient of the Gold Medal of the Royal Agricultural Society of England, awarded for services to agriculture.

A Tribute to Sir John McFadyean

It was a happy thought that prompted some of his colleagues to obtain Sir John McFadyean's consent to allow them to design and edit the December (1937) number of the *Journal of Comparative Pathology and Therapeutics* as a jubilee number and *Festschrift*. This number forms the conclusion of the fiftieth volume of the journal, which was founded by Sir John McFadyean in 1888, and has since been edited by him almost entirely single-handed, and this unique occasion has been utilized to issue this number as a *Festschrift* in honour of Sir John's outstanding contributions to veterinary science during his long career. These have been mainly confined to problems concerning the control of tuberculosis, contagious abortion and glanders among farm animals, the etiology and occurrence of Johne's disease in Great Britain, and the discovery that the virus of horse sickness is a filterable one. The esteem in which Sir John is held is manifest from the contributions contained in this number, which come from all parts of the world. Appreciations of the man and his work are contributed by many, including Sir John Kelland of the Ministry of Agriculture and Fisheries; Sir Robert Muir; Sir John Ledingham; Prof. von Ostertag, Tubingen; Dr. Schmaltz, Berlin; Prof. Leclainche, Paris; Dr. Mohler, United States; and Dr. Hilton, Canada. Several excellent portraits of Sir John are reproduced.

Dr. H. J. Gough, M.B.E., F.R.S.

Dr. H. J. Gough, superintendent of the Engineering Department of the National Physical Laboratory, has been appointed to the new post of director of scientific research at the War Office. Dr. Gough will be directly responsible to the director-general of munitions production for the general direction and organization of research work for War Office purposes; for advising as to the programme of research work to be undertaken and as to proposals for specific investigations; and for the efficiency of the organization for research and experimental purposes of the various research organizations under the War Office. He will represent that Department on the various interdepartmental research organizations.

Tercentenary of Two French Botanists

The year 1638 saw the birth of two notable French botanists, Guy-Crescent Fagon, who was born in Paris on May 11, 1638, and Pierre Magnol, who was born at Montpellier on June 8, 1638. Both were physicians, both were connected with botanical gardens and both were members of the Paris Academy of Sciences. Fagon was a nephew of Guy de la Brosse (died 1641) who first suggested and eventually, in 1626, laid out the "Jardin Royal de herbes médicinales" in Paris, the site of which was a piece of waste ground where the refuse of centuries had collected. It is now the Jardin des Plantes. After taking his degree in medicine in 1664, Fagon offered to procure plants for the garden, and through Antoine Vallot (1594–1671) the superintendent, who was also physician to the King, was appointed to travel in the Alps, Pyrenees, Auvergne and other parts. He afterwards became professor of botany and chemistry in the garden and in 1698 was made director. It was through him that two famous botanists, Joseph Tournefort (1661–1708) and Charles Plumier (1646–1704) were sent on collecting expeditions, one to the Levant and the other to America. He wrote on tobacco, cinchona and other matters, and held high office as a doctor. He died in Paris on March 11, 1718. Magnol was associated with Montpellier all his life. He took his degree there, assisted the professor of botany, in 1694 was given the chair of medicine and three years later was made director of the botanic garden, which had been founded about 1558. His writings referred mainly to the plants which grew in the neighbourhood of his native city. He died on May 21, 1715, leaving a son, Antoine, who followed in his footsteps. The genus *Magnolia* was named after him, by his countryman Plumier.

International Ornithological Congress

The ninth International Ornithological Congress was held in Rouen during the second week in May under the presidency of Prof. A. Ghigi, rector of the University of Bologna, with M. Jean Delacour as secretary. Among the papers contributed which attracted most interest was that on his recent discovery of the Congo peacock (*Afropavo*) by Dr. J. Chapin, followed by a report on the anatomy of the bird by Mr. Percy R. Lowe. A large number of films of high merit were displayed by ornithologists of various nationalities, which showed how greatly Nature photography has advanced during recent years. Particular mention must be made of Prof. A. Allen's sound film, partly in colour, of rare and disappearing American birds and of Captain C. W. R. Knight's excerpts of the film he made when leading the National Geographic Society's 1937–38 expedition to South Africa, in which he showed three birds never filmed before—the hammerhead stork, crowned hawk eagle and secretary bird. It was agreed that the tenth International Congress should be held in America in 1942, and Dr. A. Wetmore of Washington was elected president.

International Committee for Bird Preservation

The meetings of the International Committee for Bird Preservation, which were held in Rouen immediately preceding the Ornithological Congress, were attended by the official delegates of the national sections of fourteen different countries. The main subjects of discussion were the status of the Anatidæ throughout the world and the protection of the quail; a number of reports on progress in bird preservation in various countries were contributed. The destruction of sea-birds by waste oil was also discussed and, on the proposal of Prof. Einar Lönnberg of Sweden, a sub-committee was appointed to expedite means of diminishing this serious evil. A further sub-committee was appointed to collate information with regard to Nature reserves throughout Europe with the view of promoting the establishment of further areas for this purpose. M. Jean Delacour (France) was elected president of the International Committee, Mr. Hoyes Lloyd (Canada) and Dr. P. G. van Tienhoven (Holland) vice-presidents, Mr. Percy R. Lowe (Great Britain) Chairman of the national sections of Europe, and M. Leon Lippens (Belgium) and Miss Phyllis Barclay-Smith (Great Britain) were re-appointed secretaries. A message expressing his interest and wishing success to the meeting was received from the Prime Minister of Great Britain.

Pre-Folsom Man in America

SHOULD preliminary accounts of the discovery of stone implements in Lake County, California, be confirmed in detail, it may be regarded as established that man existed in America in a period prior to that of the Folsom implements of the south-western United States, hitherto generally accepted as the earliest handiwork of man yet found on the American continent. According to a statement circulated by Science Service, of Washington, D.C., a joint expedition of the Carnegie Institution of Washington and the South-West Museum, Los Angeles, under the direction of Mr. M. R. Harrington, has found in ground disturbed by the plough on the shore of a brackish pond, Folsom implements in association with others of the Mohave type—a type recently found at Lake Mohave and another site, but of which the relation to the Folsom industry was in doubt. Further excavation on the Lake County site revealed the existence of a camp deposit, in which the Mohave type of implement occurred definitely below and antedating the Folsom implements. At about the same level was a new type of spear-head, to which the name of Borax Lake type has been given. Even more remarkable, however, was the discovery at a still lower level of older and cruder implements, mainly large scrapers and hand axes, belonging to a people "as yet an entirely unknown quantity in American archæology". It is calculated that on a conservative estimate this discovery would allow man on the American continent an antiquity of at least fifteen thousand years, as against the seven to twelve thousand years variously accepted for Folsom man.

Early Hebrew Script at Lachish

ON the return to England of the members of the Marston-Wellcome Archæological Expedition to Lachish at the close of excavations for the season 1937–38, further discoveries of examples of early Hebrew script on this site are reported (*The Times*, May 26). Three fragments of pottery have been found, which are inscribed in the Phenician-Hebrew script used in the famous Lachish letters, as well as scribings on the steps of the Lachish palace. The first of the three sherds shows five names of persons, followed by numerals, which probably represent quantities of wheat, oil or other commodity. The second sherd was found in a room with the remains of the pot from which it was broken, and is thought to be a receipt. The inscription begins with the phrase "In the ninth year", serving to recall the fact that it was in the ninth year of the reign of Zedekiah that Nebuchadnezzar came to Jerusalem and besieged it. As the house in which this sherd was found shows signs of having been burnt, it is thought possible that the receipt may have been written immediately before Nebuchadnezzar's second attack on Lachish in 588 B.C. The third inscription presents a certain similarity to the Lachish letters. It is very small, but there is writing on both sides, and it is evidently a letter, beginning "To my Lord". These inscriptions have been submitted to Prof. H. Torczyner, who was responsible for the decipherment of the series of eighteen letters discovered in 1935. The scribings on the face of one of the steps of the Palace, which the expedition is now beginning to excavate, are thought to have been the work of a schoolboy. With a rectangular drawing with lines across, and the picture of a lion, are the first five letters of the Phenician-Hebrew alphabet. These, reading from left to right, are in the same order as our alphabet, and are the earliest evidence for that order. They date from before Nebuchadnezzar's earlier destruction of Lachish in 597 B.C. From these discoveries the inference is drawn that the Phenician-Hebrew script was in general use in the kingdom of Judah and was being taught in the schools before the Captivity. After the Captivity the Assyrian-Hebrew script was employed.

Infestation of Grain by Insects

DESTRUCTION of stored grain and grain products by insects causes great loss to many sections of industry, probably amounting annually to not less than £500,000. More information is required before the problem can be completely tackled. The first step is a scientific survey which is to be made at once, during the period of seasonal activity of the insects. This survey has been organized on the initiative of the various sections of industry concerned, and the major part of its cost will be met by their contributions. It is to be carried out, under the auspices of the Department of Scientific and Industrial Research, by the Stored Products Laboratory of the Imperial College of Science and Technology. A conference has been formed of the representatives of interested bodies which have already agreed to co-operate in this work and its first meeting was held on May 26 in the offices of the Department of Scientific and Industrial Research. The co-operation of all sections of industry affected is essential to the success of any organized attack on these insect pests. The neglect of one section to play its part will jeopardize the success of the efforts of all the rest. The Conference, therefore, viewed with satisfaction the extent of the support so far accorded. Any organization or undertaking wishing to co-operate in this work should communicate with the Secretary of the Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, London, S.W.1.

Institute of Physics

THE annual report of the Institute of Physics for the year 1937, which has just been published, shows that its membership continues to increase in a most satisfactory way. It was just over a thousand at the end of the year, and is now considered to be representative of British physicists both at home and overseas. The most important activity of the Institute during the year covered by the report was the Second Conference on Industrial Physics held in the University of Birmingham in March 1937, the subject being "Optical Devices in Research and Industry" (see NATURE of April 3, 1937, p. 600). The various branches of the Institute in Great Britain held a number of meetings during the year and the committees of the overseas branches did valuable work in various ways. The report states that there was a further increase in the number of vacancies for physicists of which the Institute was notified, the figure being 197 for the year. Some vacancies for laboratory assistants were filled from among those holding the Institute's certificate in laboratory arts. The report states that the scope of the *Journal of Scientific Instruments*, which is produced by the Institute in co-operation with the National Physical Laboratory, has been enlarged to include items dealing with the applications of physics to industry.

A Proposed Scientific Film Society

A SCIENTIFIC FILM GROUP of the Association of Scientific Workers was formed about a year ago to encourage the growth of good instructional and documentary films, dealing both with 'pure science' and, perhaps even more important, with science as a social force. The Group has accordingly given shows of approved scientific films in London, Cambridge, Oxford and elsewhere, which have demonstrated that there is a considerable public for such films. To enable this work to continue on a more ample scale in London, however, while complying with L.C.C. regulations, it has now become necessary to consider forming a Scientific Film Society. Such a Society would be open to all interested persons, whether members of the Association of Scientific Workers or not, and would give at least four film shows a year in a London cinema on Sunday afternoons. It would not be possible to sell tickets for such shows to the general public, but a limited number of guest tickets would be available to members. Any profits arising from the Society's work would be devoted exclusively to non-commercial purposes such as the making and adapting of scientific films. Further particulars about the proposed Society can be obtained from the honorary secretary of the Scientific Films Committee, Association of Scientific Workers, Kelvin House, 28 Hogarth Road, London, S.W.7.

Joint Committee on Materials and their Testing

UNDER the above title, an interesting new form of collaboration between twenty-five of the major scientific societies and technical institutions of Great Britain has been effected: the Committee has now issued its first annual report, rendered to the councils of the collaborating institutions concerned. The principal objects of the Joint Committee are threefold: (1) to promote joint discussions on the wider aspects of the subjects of materials and their testing; (2) to assist a co-operating institution or society in the presentation of a paper or group of papers dealing with a more detailed aspect of one of these subjects; and (3) to undertake those duties with regard to international matters which properly devolve on the Joint Committee in accordance with its terms of reference. The main activity in the period reviewed by the report was the organization of a general discussion on "Notched Bar Testing" held in Manchester on October 29, 1937, in which this interesting subject was reviewed in relation to research and opinion at home and abroad. Four comprehensive papers were submitted and these papers, together with a record of the most informative discussion which resulted, are now available in pamphlet form, obtainable on application to the secretary of the Manchester Association of Engineers. The Committee is now organizing a second general discussion on various aspects of "Non-destructive Testing", which will centre around papers presented by selected experts in Germany, Holland, the United States and Great Britain, on the use of X-ray, gamma-ray, magnetic, electrical, aeronautical and other more general methods: this discussion will take place in London in October or November of the present year. The pooling of the efforts of technical bodies in promoting discussions in the wide and most important fields of the materials of construction should go a long way towards satisfying a long-felt want, and the further activities of the Joint Committee will be followed with much interest in scientific and technical centres.

Magnetic Recording in Broadcasting

IN a paper read by A. E. Barrett and J. C. F. Tweed to the Institution of Electrical Engineers on December 1, some of the methods of recording sound, especially those in connexion with their applications to Empire broadcasting, were considered. In Great Britain, very little information has been published on the subject of magnetic recording on steel tape. Dr. Stille, a German engineer, was the first to use steel tape for recording, and he made notable advances in the necessary technique. The British Broadcasting Company first tested the system in 1930 when the Empire broadcasting service was being inaugurated. Extracts from the home programmes were recorded and afterwards reproduced in the Empire transmission. The first important programme to be radiated to the Empire by this means was that on Christmas Day 1932. It included a speech by King George V. Early in 1933, Marconi's Wireless Telegraph Co., Ltd., designed a machine in which many of the mechanical difficulties experienced with earlier models were successfully overcome. It has been developed further by both the Company and the B.B.C. Magnetic recording in its simplest form can be carried out by passing a length of steel tape at constant velocity through an electromagnetic device, called a recording head, which produces variations in the magnetism of the tape. Reproduction is effected by passing the magnetized tape at the same velocity through a device called the reproducing head, which is sensitive to the changes in the magnetism in the tape. In the ideal case these correspond to the original alternations applied to the recording head. When a new record is wanted, it is necessary to remove the previous variations in the magnetism before recording. This is done by passing the tape through a 'wiping head' which strongly magnetizes the tape. The wiping, recording and reproducing heads used in the experiments described by the authors have different types of coils and pole-pieces, but are in other respects identical.

British Museum (Natural History): Recent Acquisitions

A COLLECTION of 2,300 otoliths or 'ear-bones' has been purchased for the Fish Section of the Zoological Department. These specimens represent 570 different species, and were collected by Mr. G. A. Frost over a period of thirty years. This is the largest and most important collection of otoliths in existence, and it is especially valuable because it formed the basis of a series of papers published by Mr. Frost between 1925 and 1930. The most important gift to the Department of Entomology is the collection of Lepidoptera formed by the late Mr. Edward Meyrick. The collection is estimated to contain more than 100,000 specimens. Among the more important accessions to the Department of Geology is a collection of bones from the Lower Miocene of Kenya, including remains of mastodons, antelopes, rhinoceroses and dinotheres, collected by Archdeacon W. E. Owen; also a very fine series of the remarkable creature *Palæospondylus* from the Middle Old Red Sandstone of Achanarras, Caithness, collected and presented by Mr. C. Forster-Cooper, now the director of the museum.

PURCHASES in the Department of Mineralogy of the Museum include good crystals of cassiterite (tinstone) from Bolivia and three remarkably fine nodules of Variscite from Fairfield, Utah. The nodules, two of which are about a foot across, have been cut through and polished to show the beautiful colour of the mineral, which is nearly related to turquoise. From the same source have been obtained five splendid crystals of wulfenite (lead molybdate) from Red Cloud mine, Yuma county, Arizona. In this connexion it is of interest that Mr. A. W. G. Kinsbury, of Chewton Mendip, has recently rediscovered the mineral wulfenite at Higher Pits, Priddy, in the Mendips, and has recently presented specimens to the Museum. Four meteorites new to the collections have been acquired. The Department of Botany has received 582 specimens of flowering plants collected by Dr. Hugh Scott and Mr. E. B. Britton on the recent expedition to south-west Arabia, a district little known botanically, but historically famous by the collections made in 1775 by Linnæus's student Forskal. Also a collection of 382 specimens collected in Greenland and Ellesmere Land has been presented by Mr. R. W. Feachem. The purchases include 2,000 paintings of fungi by the late Dr. Knauth which will be of very great value in making identifications.

Research at Millport

THE annual report of the Scottish Marine Biological Association for 1936–37 shows that much good work is in progress. A scheme has been prepared for extension of accommodation which it is hoped will soon be carried out. Among other things, the library space will be considerably enlarged. Work on the growth and food of the herring has been continued by Drs. Orr, Marshall and Nicholls, mainly on the young herring. In 1935 the life-history of the herring was followed from hatching in March to metamorphosis at the beginning of June. Since July 1936 catches have been made every fortnight up to the present time in the immediate neighbourhood of the laboratory. The largest numbers were caught at dusk. Work on algal ecology has been continued by Dr. D. C. Gibb, and on animal ecology by Mr. A. J. Haddow on the growth of *Sertularia*, and by Dr. E. E. Watkin on the Amphipod genus *Bathyporeia*. In view of the failure of the herring supplies during the winter, a number of fishermen have turned their attention to "clams" as *Pecten maximus* is called locally. Preliminary work on this mollusc indicates that at five years it measures 4 inches wide, growth being indicated by winter rings, and it takes four years to reach a marketable size. It therefore grows too slowly to maintain for long the call now being made on the reserves of the species. Interesting results from examining the stomach contents of shags and coromorants are shown. The shags visiting sandy areas feed on shrimps and polychætes and on rocky shores eat prawns (*Leander*).

Vitamin B_1

WE have received from Messrs. Merck and Co. an illustrated brochure of upwards of fifty pages entitled "The Story of Vitamin B_1", which gives an up-to-date account of the chemistry, physiology and nutritional value of the vitamin. To each section is appended a useful bibliography, from which those interested can obtain more detailed information than it is possible to give in a summary review. The information supplied, nevertheless, covers the field remarkably well and brings together work which is scattered in numerous journals, so that the reader obtains a picture of our present knowledge of the vitamin in all its aspects and is readily able to see how far the work of different authors is in agreement or otherwise. After an account of the chemistry and synthesis of the vitamin, a useful section is devoted to the question of its standardization and the relationship of the different "biological units" to the international unit, information which is not readily available in summary form. Our knowledge of its physiology is then reviewed, and the following sections are devoted to its value in human and animal nutrition, the normal human requirements and the effects of a subnormal intake. The brochure is not intended for general distribution, but will be sent to investigators in the field of vitamin therapy, to medical specialists, food chemists, research workers in human and animal nutrition, colleges and universities, Government agricultural and experiment stations, and manufacturers of pharmaceutical and proprietary products.

National Physical Laboratory Abstracts

AFTER the publication of the volume of "Collected Researches" of the National Physical Laboratory at present in the press, that quarto publication will cease and will be replaced by an annual octavo pamphlet entitled "Abstracts of Papers", the first issue of which, for the year 1936, has already appeared. It extends to 65 pages, 61 of which are devoted to 140 abstracts and the rest to author and subject indexes. The title of each abstract is in Clarendon type and that of the publication in which the complete paper is to be found in italics with specification of year, volume and page. The abstracts themselves generally give the object and method of the investigation concerned in outline and the net results in detail, so that a large amount of valuable information is condensed into a small space. They are grouped under subjects. The present issue is published at 1*s.* by H.M. Stationery Office.

Esperanto for Scientific Papers and Abstracts

THE "Universala Esperanto-Kongreso" is to take place this year at University College, London, on July 30–August 6. A recent article by Dr. D. R. Duncan, published in the *Scientific Worker*, directs attention to the great potential value of Esperanto as a means of intercommunication between men of science. Being "intelligible to any educated European" without previous study, it is eminently suitable for scientific abstracts in cases where the original paper was published in a language little known outside its own country. Reports consisting largely of tables such as the "International Critical Tables" might well, it is suggested, use Esperanto instead of numerous parallel columns in different languages. Esperanto is, it appears, much used in Japan for scientific papers. A few journals outside Japan give Esperanto summaries at the end of papers published in the journal's own language, for example, the *Bull. Soc. Française des Electriciens*, the *Phare Médical* and the *Revista da Sociedade de Geografia do Rio de Janeiro*.

Society for Extending the Rothamsted Experiments

HIS GRACE THE DUKE OF DEVONSHIRE has consented to accept the chairmanship of the Incorporated Society for Extending the Rothamsted Experiments which had been held by his late father since the inception of the Society in 1904. The vice-chairmen are the Earl of Radnor and Lord Clinton. The purpose of the Society is to foster the development of the work carried out by the Rothamsted Experimental Station: the last important effort was to raise the funds for the purchase of the agricultural part of the Rothamsted Estate, which was successfully achieved in 1934, and its next effort will be in connexion with the centenary of the foundation of the Rothamsted Experimental Station which falls due in 1943.

Growth of a Sunspot

BETWEEN May 22 and 24, a large group of sunspots suddenly appeared near the central meridian and became visible to the naked eye. Measures of area taken from the Greenwich photographs show the following rapid increase in size of the spot group, which began as two or three tiny spots. The areas are corrected for foreshortening and are expressed in millionths of the sun's hemisphere.

May	22·4	U.T.	10	millionths
,,	23·3	,,	210	,,
,,	24·3	,,	1060	,,
,,	25·4	,,	1200	,,
,,	26·3	,,	1390	,,
,,	27·3	,,	1570	,,

Since the average group of this size takes about 8–10 days to develop fully, the very great increase in area during the first 48 hours suggested that the group would be unusually large, exceeding perhaps 2500 millionths. The maximum size appears, however, to have been reached about May 27 or 28, the group passing out of view at the western limb on May 30. These sunspots, in about latitude 8° north and longitude 12°, offered several points for study with an ordinary telescope. There was, for example, a marked drift equatorwards of the leader spot amounting to 3° or about 37,000 km. between May 24 and 27. The changes in structure between May 23 and 24 were also considerable. During the initial development of the group, the accompanying hydrogen flocculi seen spectroscopically in $H\alpha$ (and at times in $H\beta$) were persistently of enhanced intensity, although no outstanding short-lived eruptions were observed at Greenwich. The time of central meridian passage of the group was May 23·8, and it will return to the central meridian on June 20, unless by then the spots have dispersed.

Announcements

WE regret to announce the death of Dr. J. W. Mellor, C.B.E., F.R.S., author of "A Comprehensive Treatise on Inorganic and Theoretical Chemistry", on May 24, aged sixty-eight years; and of Prof. W. Stroud, Cavendish professor of physics in the University of Leeds in 1885–1909, director of Barr and Stroud, Ltd., Glasgow, on May 27, aged seventy-eight years.

SIR FRANK SMITH, secretary of the Department of Scientific and Industrial Research, has been elected an honorary fellow of the Institute of Physics. This, the highest distinction the Institute can confer, is reserved for those whom it especially desires to honour for exceptionally important services in connexion with physics or a science allied thereto; there are only seven other honorary fellows. Sir Frank Smith was a founder fellow of the Institute, and did much to help establish it on the sound basis which has assisted so much in its rapid development.

MR. A. H. R. FEDDEN has been elected president of the Royal Aeronautical Society for the year 1938–39.

THE annual inspection of the field plots and laboratories of the Rothamsted Experimental Station will be held on June 29, beginning at 11.15 a.m. Further information can be obtained from the Secretary, Rothamsted Experimental Station, Harpenden, Herts.

We are informed that J. Wadsworth has resigned the directorship of Apia Observatory, Western Samoa, and expects to leave Samoa shortly.

Major-General C. H. Foulkes writes: "It has been suggested that my review in Nature of May 21 of Prof. Kendall's book 'Breathe Freely' might give the impression that the author is 'anti-A.R.P.'. This was very far from my intention, and in view of recent events in Spain and China, it need scarcely be said that no reasonable person could adopt such an attitude."

To encourage the reading of papers by students of fuel technology, the Council of the Institute of Fuel has decided to make an annual reward of a medal, together with a prize consisting of books and/or instruments to the value of £5 for a paper submitted by a student member of the Institute or by any student less than twenty-five years old of a university or technical college in the United Kingdom. Further particulars can be obtained from the Secretary, Institute of Fuel, 53 Victoria Street, London, S.W.1.

The twenty-seventh annual meeting of the Oxford Ophthalmological Congress will be held at Keble College on July 6–9. Further information can be obtained from the honorary secretary, Dr. F. A. Anderson, 12 St. John's Hill, Shrewsbury.

The twenty-fourth annual conference of the National Association for the Prevention of Tuberculosis will be held in the Great Hall of the British Medical Association House, Tavistock Square, W.C.1, on June 30–July 2.

At the International Congress Against Rheumatism recently held at Oxford, Prof. Ralph Pemberton of Philadelphia was elected president of the International League Against Rheumatism in succession to Dr. R. Fortescue Fox. The next Congress is to be held in New York in 1940.

The Jessie Macgregor Prize in Medical Science will be awarded next July for the best record of original work on the science of medicine. The work may be published or unpublished, but must not have been published more than three years earlier than July 1938. The value of the prize is about £50, and it is open to medical women graduates of the University of Edinburgh. Applications should be made to the Convener of Trustees, Royal College of Physicians, Edinburgh, not later than June 30.

Dr. Rudolf Kreutz, of Cologne, has been awarded the Sudhoff Medal by the German Society of the History of Medicine.

Dr. Herbert Hoover, the former president of the United States, has been given an honorary doctorate of the Technical University of Vienna.

Dr. Carl Landsteiner, of the Rockefeller Institute, New York, has been awarded the Cameron Prize of the University of Edinburgh, for his work on blood grouping and blood transfusion.

The John Phillips Memorial Medal of the American College of Physicians was recently awarded to Dr. Harry Goldblatt, professor of experimental pathology, Western Reserve University School of Medicine, Cleveland, for his work on the production of experimental hypertension in animals.

A monument to the late Mme. Curie was unveiled in Roosevelt Park, Raritan Township, New Jersey, on April 24, the seventieth anniversary of her birth.

An Argentine Institute of Nutrition attached to the Ministry of Foreign Relations has recently been founded at Buenos Aires.

The third International Congress for the Study of Goitre will be held on September 13–14 at Washington, when the following subjects will be discussed: (1) endemic goitre, cretinism and myxœdema; (2) thyroid gland and metabolism, nutrition and endocrine glands; (3) hyperthyroidism. Further information can be obtained from Dr. Allen Graham, 2020 East 92nd Street, Cleveland, Ohio, U.S.A.

The sixteenth International Congress of Physiology will be held at Zurich on August 14–18 under the presidency of Prof. W. R. Hess. It will consist of six sections devoted respectively to general and comparative physiology, biophysics, biochemistry, applied physiology (work, sport and aviation), psychophysiology and pharmacology. Further information can be obtained from Prof. E. Rottlin, Sonnenweg 6, Basel, Switzerland.

A Note upon the "Scialyscope", which provides a means by which surgical operations may be viewed by a number of students in a room adjacent to the operation theatre, was published in Nature of April 30, p. 780. Mr. G. Davidson, director of Technical Lights and Equipment, Ltd., 9–10 Bentinck Mews, Marylebone Lane, London, W.1, sends us a copy of a booklet compiled when the instrument was originally invented, as well as copies of illustrated French leaflets and a booklet showing installations of it at different hospitals. Further information can be obtained from that firm.

Erratum. In Nature of May 28, p. 980, paragraph entitled "Condensation on Board Ship", line 2, for "J. S. Duly" read "S. J. Duly".

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1018.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

A Method of Investigating Electron-Inertia Effects in Thermionic Tubes

IT is well known that the phenomena exhibited by thermionic vacuum tubes begin to alter when the frequency of the potential applied to their electrodes is increased so as to approach the inter-electrode transit-time of the electrons. It is convenient to group all these phenomena under the name of electron-inertia effects. They include the production of high-frequency oscillations by the magnetron and the Barkhausen-Kurz method, and the occurrence at very high frequencies of a phase shift of the conductance of a diode and of the mutual conductance of a triode, and increased damping in the grid circuit of a triode.

Many theoretical investigations of these effects have been made, but it is not easy to subject them to experimental test because of the difficulties encountered in working at the very high frequencies involved. It is, for example, very difficult to measure the amplitudes or phase relations of the potentials and currents, and if it is desired to apply high-frequency potentials to the electrodes in a search for resonance effects, it is generally necessary to do so by means of a Barkhausen-Kurz oscillator, the amplitude and frequency of which are not conveniently varied. If the frequencies of the oscillations involved in these investigations could be made very much smaller, the experiments would be much easier, and could be carried out in considerably greater detail.

This desirable effect can be achieved if, instead of electrons, more massive ions are used. It can be demonstrated that, in a tube with given potentials on the electrodes, the equations of motion for an ion of mass M are the same as those for an electron of mass m, provided the emission current is decreased in the ratio $\sqrt{m/M}$ and the time in all the equations is increased in the ratio $\sqrt{M/m}$. As a source of positive ions, it is convenient to use either a tungsten filament situated in a vapour of cæsium, according to the method first explained by Langmuir[1], or a platinum strip coated with an emitting substance, as described by Jones and Blewett[2].

In an investigation of some electron-inertia effects, we have used tubes of both kinds. A cæsium tube was made from the electrode system of an A.T. 40 triode, and a tube with plane electrodes having a variable spacing was used with a lithium emitter of the Jones and Blewett type. The more detailed experiments were made with the cæsium tube. An accelerating potential was applied to the grid and a small retarding potential to the plate, so that in the absence of any oscillating potentials no current was received by the plate. An ordinary retroactive oscillator was used to apply to the plate a high-frequency potential of amplitude less than the steady retarding potential. For most values of grid potential, no steady plate current was observed, but certain values of potential gave rise to a flow of plate current. The value of grid potential which gave rise to this plate current was dependent upon the frequency of the oscillating potential applied to the plate, and the phenomenon was presumably due to a resonance between the frequency of the applied E.M.F. and the frequency of oscillation of the ions about the grid wires. Similar results have been given by Gill and Donaldson[3] for an electron triode. If this is the correct explanation, the theoretical relation[4]

$$\lambda \sqrt{E_g} = 2{,}000\, d_g \sqrt{M/m} \qquad (1)$$

should hold between the grid potential (E_g) in volts, the wave-length (λ) in cm. corresponding to the applied frequency, and the grid diameter (d_g) in cm. This relation was, in fact, found to hold approximately. The wave-lengths lay between 300 m. and 800 m. for values of E_g between 450 and 75 volts, whereas if electrons had been used the wave-lengths would have been of the order of 1 m. It was found that the closeness with which expression (1) was obeyed depended on the amplitude of the applied potential, and on the emission current. We hope to give a detailed account of these effects elsewhere: the purpose of the present note is simply to direct attention to the method of investigation.

Similar effects were observed when the plane electrode tube was used with lithium ions. Equation (1) was again found to hold approximately, and was also found to represent correctly the effect of altered electrode spacing. With the lighter lithium ions the wave-lengths involved were of the order of 100 m. for potentials of the order of 200 volts and electrode spacing of the order of 1 cm.

It should be pointed out that since the emission currents in the case of positive ions are small, the effective impedance of a tube is large, and it has not been possible to use the above-mentioned tubes to produce oscillations of the Barkhausen-Kurz type. By making a cæsium vapour tube with a large emitting surface and by keeping the bulb at a high temperature so as to increase the emission current, we hope to be able to produce Barkhausen-Kurz type oscillations and investigate the mechanism of their production.

S. KOWNACKI.
J. A. RATCLIFFE.

The Florisbad Skull

SINCE its discovery by Prof. T. F. Dreyer[1] in 1932, the Florisbad skull has been discussed by the leading anthropologists[2] of South Africa. No one in Europe, so far as I know, has had an opportunity of examining a cast of the specimen. Thanks to Prof. Raymond Dart, of Johannesburg, I have been given this opportunity, and as a result I wish to confirm the importance of the discovery to all students of human evolution.

The primitive Rhodesian skull found in the mine at Broken Hill in 1921 is no longer an isolated antique. The Florisbad skull reproduces the massive and peculiar features of the Rhodesian forehead. But behind the forehead, the Florisbad skull assumes the characters of the Boskop skull. Indeed it may be regarded, as Dr. Alex. Galloway has maintained, as a transition from the Rhodesian to the Boskop type, the latter heralding the modern races of South Africa—Bushman and Hottentot. In its cheek bones and its upper face, the Florisbad fossil reproduces features seen in modern Bushmen and Hottentots. This new skull is a mosaic of Rhodesian, Boskop and Bush characters.

The geological ages of the Rhodesian and Boskop fossils are not known, but from the very primitive features of the Rhodesian skull and brain, one is tempted to ascribe it to a mid-pleistocene date. The large-brained Boskop skull one supposes to be much later in date—perhaps upper pleistocene. The Florisbad skull was found in a stratified deposit at a depth of 20 ft. The stone implements and fossil fauna found with the skull has led Prof. Dreyer to assign it to an early phase of the Middle Stone industry of South Africa. We may presume, therefore, that Florisbad man may have been contemporary with the Neanderthal race of Europe.

The brain of Rhodesian man measured about 1,300 c.c.; that of the Boskop man about 1,600 c.c.; that of the Florisbad man about 1,450 c.c.

The discovery of the Florisbad skull supplies evidence I have been in need of. The discoveries of fossil types already made leaves little doubt that South Africa, like Java, has been a centre where evolutionary change pursued its own independent course, ending in the Bushman and Hottentot types of to-day. It seemed hazardous to presume that the Rhodesian type, with its great supraorbital ridges and small brain, could be transformed into the Boskop type, with voluminous brain and smooth forehead, but that such a transmutation has really occurred seems to be assured by Prof. Dreyer's discovery.

ARTHUR KEITH.

Buckston Browne Farm,
Downe, Kent.

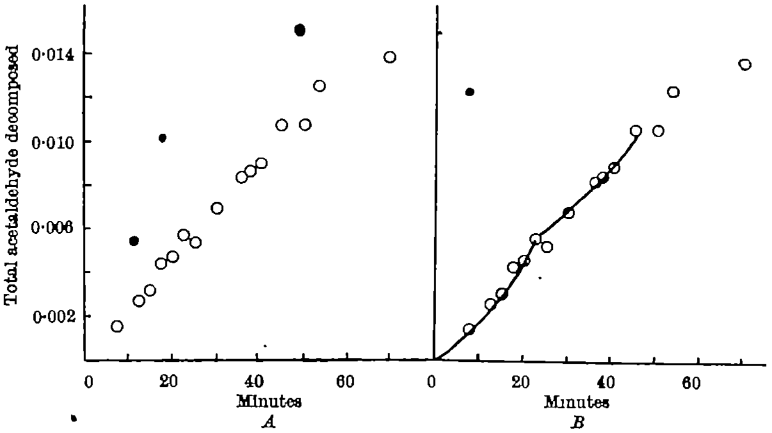
Decomposition Reactions of Organic Compounds in the Gaseous State

IN NATURE and elsewhere, Prof. M. W. Travers and his collaborators have published the results of experiments on gaseous decomposition reactions, and have claimed that in a number of respects their results invalidate work published from this laboratory in the course of the past twelve years. So long as these views have appeared as the expression of the personal point of view of Prof. Travers, I have not wished to intervene, but since I have seen statements from which I differ strongly repeated at second-hand, I ask leave to make two comments.



(1) Some of the statements made in the papers of Prof. Travers convey the impression that we have relied uncritically on pressure changes as indications of reaction rates. This is not correct. In some cases the reaction has been followed by analytical methods over its whole course[1], and in others a mathematical method has been used to show that the pressure changes employed were in fact proportional to the initial transformation rate over the whole range used[2].

(2) I am not competent to summarize the views of Prof. Travers, since I am far from understanding them, but the major difference of opinion relates to the degree of complexity of certain processes. According to Prof. Travers, in the thermal decomposition of, for example, acetaldehyde "the initial stages of thermal decomposition show strong self-acceleration, followed by a sudden slowing down. This slowing down is always accompanied by the speeding up of another process, but it generally happens that the secondary process begins to speed up before the break point, and slows down again after the break point is passed".

In the accompanying graphs, I have plotted in *A* the results given by Seddon and Travers[3] for the decomposition of acetaldehyde at 400°. It seems to me quite obvious that these points are grouped within the experimental error about a single curve somewhat concave to the time axis, an interpretation which would have tallied with our results and with those of Letort. (Seddon and Travers admit the possibility of a slight error in the initial timing.) In *B* is reproduced the curve which Seddon and Travers draw through the *same points*.

This summarizes and typifies the main matter at issue between the two schools of thought. Prof. Travers has given his evidence and stated his beliefs as he has every right to do, but since the conclusions are now being reported without an examination of the evidence itself, I feel compelled to direct attention to the nature of the observations, and to say that in my opinion they are of a kind inadequate to justify the kind of deductions which have been made from them about the kinetics of these reactions.

Electron Multiplier as an Electron Counting Device

In an earlier communication[1], I have described the possibility of using an electron multiplier, based on the secondary emission principle, for the detection of individual electrons by cooling the multiplier for the purpose of suppressing the thermal emission in liquid air. I stated there that this method of counting individual electrons does not necessarily require the use of liquid air, provided multiplying electrodes, with fairly great secondary emission factor and sufficiently high work function are used. There is a large discrepancy in the data of various papers published on the subject of work function and secondary emission of a surface. Experiments had to be carried out to determine whether a surface satisfying our requirements could be found, and we found the following surface satisfactory from the above point of view:

Very thin layers of barium oxide on a nickel base activated by the method normally used for oxide-coated cathodes will easily give a multiplication factor of $T = 2{\cdot}5$, with a primary electron velocity of 200 volts. A multiplication of about 10,000 times was achieved in a ten-stage multiplier. The thermionic emission (at room temperature) and field emission of the active surfaces in this multiplier are negligible.

On this basis an apparatus was built consisting of the above multiplier and an amplifier with a cathode ray tube. The zero effect of the counting device was about 5 per minute. It was possible to detect individual electrons emitted by the cathode when illuminated by a very weak beam of light or by heating the cathode by a built-in heater. The small zero effect is probably due to cosmic rays. The device can also be used for the counting of gamma rays.

The maximum resolving ability of the above multiplier with an amplifier of suitable construction is 10^{-8} sec.; this greatly surpasses that of the gas-filled counters.

Further details will appear in a paper to be published elsewhere.

Rectifying Properties of Crystals

B. K. Sen[1] has recently reported in NATURE, that the rectifying properties observed by Khastgir[2] were found also in some crystals having a centre of symmetry. As in this case a volume rectification must be excluded, Sen concludes that generally the observed rectifying properties should be ascribed to a superficial phenomenon.

So long ago as 1935, I reported the results of experiments on unipolar conduction in carborundum monocrystals, in the direction of the principal polar axis. The experimental procedure I used enabled me to distinguish between a superficial rectification of the 'blocking layer' type, and a true volume rectification. This volume rectification is very less marked and in opposite direction to the surface rectification.

The facts observed by Khastgir must be ascribed substantially to a very strong superficial effect. On the other hand, my experiments demonstrate the existence of a true volume rectification, the existence of which is a natural consequence of the lack of symmetry in a crystal with polar axis[4].

There are thus three different cases:

(1) Deaglio's experiments (true volume rectification).

(2) Khastgir's experiments on carborundum (energical surface rectification concealing the volume rectification).

(3) Sen's experiments on crystals with centre of symmetry (surface rectification only).

Formation of Negative Ions at Surfaces

In a recent series of papers[1], one of us (F.L.A.) has discussed experiments, carried out with the assistance of Dr. J. C. Milligan, which led to the discovery of a new process of negative ion formation. This process was the formation of negative ions at metal surfaces by bombardment of the surface with positive ions, the negative ion being presumably formed by the positive ion capturing two electrons from the surface. After acceleration away from the surface, the negative ion has an excess energy which is acquired from the acceleration of the positive ion towards the surface. Dr. R. A. Smith[2] has recently carried out a quantum theoretical investigation of the above process which satisfactorily accounts for the experimental results.

Further work carried out during the past year has shown that the negative ion emitted from the surface need not necessarily be of the same element as the positive ion which leads to its formation. Sloane and Press[3] report in to-day's NATURE that they have repeated these experiments and have come to the same conclusion.

Our new results show that five peaks of light negative ions are obtained by the mass-spectrograph when the electrodes are bombarded by positive ions of argon or nitrogen or mercury, and that practically identical negative ion curves are produced by each type of positive ion. The probable mass numbers of these peaks are about 16, 24, 32, 37, and 44. In each set of curves, using positive ions of argon, nitrogen or mercury, the peak of mass number about 24 (possibly C_2H) is about a hundred times as strong as any of the other peaks. All the negative ions have excess energy and increase in intensity with increase of the positive ion current. With the filament properly degassed and liquid air on all traps, no peaks are detectable, thus showing that good vacuum conditions can be obtained in our apparatus. These new results show that no negative ions of nitrogen are formed, the N^- peak formerly reported being probably O^- produced from occluded oxygen in the surface ejected by the impact of nitrogen positive ions, as is shown to occur below.

The apparatus was then flushed out with oxygen and several runs taken in this gas. The negative ion analysis curves were now entirely different from those obtained in argon, nitrogen and mercury vapour. The main peaks in oxygen were those of mass number 16 and 32, representing O^- and O_2^-. The O^- peak was very intense, being 140 times as high as it was in the other gases. The O_2^- peak had increased by a factor of about 65. The peak at about 24, which was so intense in argon, nitrogen and mercury vapour, was barely perceptible, as were also the other peaks.

The oxygen was then all pumped out and the electrodes bombarded with positive ions of mercury by removing the liquid air traps. The main peak in the analysis curves of negative ions produced on the filament was still O^-, being 24 times stronger than any other peak. For the ions produced on the gauze electrode E_2 of our apparatus[1], the main peaks were those of mass numbers 24 and 32. Re-flashing the filament considerably reduced the O^- peak from the filament, but had no marked effect on the ions from E_2.

The results in oxygen, which are in agreement with those already published[1], appear to show that both O^- and O_2^- are produced by positive ions of oxygen capturing two electrons from the surface, as was previously suggested. However, these ions can also apparently be produced by bombardment by positive ions of mercury of a surface which has absorbed oxygen. Flashing of the filament reduces its content of absorbed oxygen, and so reduces the O^- peak from the filament. The other peaks probably arise in the same way from other gases and vapours either occluded in the metal or adsorbed as a monomolecular layer on its surface.

The latter mode of formation of negative ions of one element by bombardment of the surface with positive ions of another element may be due to a collision of the second kind. Thus a positive ion of mercury, nitrogen or argon may capture an electron into an excited state, the excitation energy being transferred to a gas atom on the surface by a collision of the second kind. This excited atom then captures a second electron from the metal by a resonance process. This mode of formation is the same as the one formerly suggested (by F.L.A.) to account for those negative ions which are formed from their own positive ions, except that in the new process transfer of excitation and kinetic energy occurs between the two species of atoms.

When a high yield[2] of light negative ions is produced by Hg^+ ions, the number of Hg^- ions formed would be considerably decreased. This may account for their not having been observed by Sloane and Press[3].

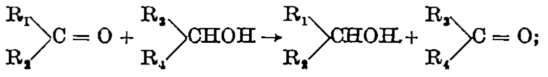
Photochemical Interaction between Ketones and Secondary Alcohols

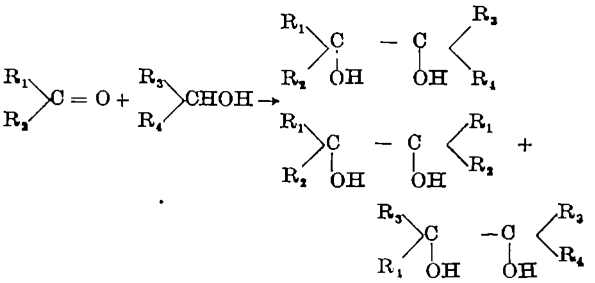
IT has been observed by various authors[1] and recently confirmed by an extensive investigation in our laboratory, that under the influence of ultraviolet light, secondary alcohols and ketones undergo a process of mutual oxidation and reduction. This can consist of a complete hydrogen exchange,



$$\begin{matrix}R_1\\R_2\end{matrix}\!\!>C=O+\begin{matrix}R_3\\R_4\end{matrix}\!\!>CHOH\rightarrow\begin{matrix}R_1\\R_2\end{matrix}\!\!>CHOH+\begin{matrix}R_3\\R_4\end{matrix}\!\!>C=O;$$

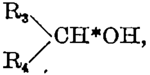
(i)

or of the formation of pinacols,



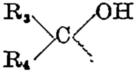
(ii)

In both cases the characteristic reaction is the migration of the hydrogen atom H* of the alcoholic group



$$\begin{matrix}R_3\\R_4\end{matrix}\!\!>CH^*OH,$$

which may occur in an addition compound formed primarily from the alcohol and the ketone[2]. (That the hydroxylic hydrogen atom is not primarily required for the reaction follows from the fact that similar condensation reactions occur between ketones and the methyl ethers of secondary alcohols.) The radical



$$\begin{matrix}R_3\\R_4\end{matrix}\!\!>C\!\!<\begin{matrix}OH\\ \cdot\end{matrix}$$

can be stabilized by giving up the hydrogen atom of the hydroxyl group or by combining with a second, similar radical, the actual course of the reaction probably depending on the nature of the reactants.

It is probable that dissociation of the C—H* group is not the primary photochemical reaction. As a matter of fact, phenylmethylcarbinol, $C_6H_5.CHOH.CH_3$, is not racemized by ultra-violet irradiation, although dissociation of the C—H*-bond would have such an effect due to the configurational instability of radicals[3]. On the other hand, irradiation of an equi-molecular mixture of optically active phenylmethylcarbinol and acetophenone gives an optically inactive mixture of the diastereomeric acetophenone-pinacols, although one of them could have been formed in the active state. So we are led to the assumption that the primary photochemical step is the activation of the carbonyl compound, which is in accord with the known absorptive capacity of carbonyl compounds, and the relative transparency of alcohols. This activated form, for example, the diradical  $\begin{matrix}R_1\\ \\ R_2\end{matrix}\!\!>\!\underset{:}{C}\text{—}\underset{:}{O}$ [4], reacts with the alcohol, $(R_3)(R_4)\dot{C}HOH$, splitting the C—H* bond and giving two free radicals — configurationally unstable — which can dimerize symmetrically or asymmetrically (II) or stabilize by a second oxidation-reduction process (I).

The above facts and considerations are able to throw some light on the photochemistry of ergosterol and similar compounds. Irradiation of ergosterol in a neutral solvent gives lumisterol without configurational change in the secondary alcoholic group CH*OH [5], but in presence of an acceptor compound (eosine) which suffers activation first, the H* is removed and a bimolecular product (ergopinacol)[6] is formed[7].

A detailed report on our experiments will be published elsewhere.

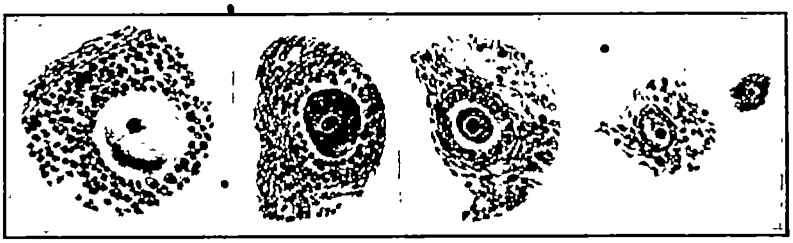
Ovotrophic and Folliculoplasic Hormones

RECENT findings have forced me to distinguish the nucleotrophic or *mitoplasic* from the *plasmotrophic* effect of hormones; plasmotrophy being tissue growth by cellular hypertrophy alone, mitoplasia, growth by mitogenesis as well.

Those hormones of the steroid series which have at least *one* oxygen-bound valency in the — 17 position are usually mitoplasic; for example, œstrone. Colchicine, by arresting mitosis in the metaphase, helps to reveal mitoplasia (Dustin and co-workers), a dosage of 4 γ per gram body weight being optimal for mitotic immobilization at least fifteen hours after injection in the rat.

Pituitary hormones are generally plasmotrophic, as seen by their effect on such tissues as cartilage, mammary gland, adrenal cortex, corpus luteum, thyroid, and the interstitial cells of Leydig. The cells of the ductless glands secrete hormones when enlarged, this secretory capacity being latent when they become atrophic owing to the absence of the anterior pituitary. In general, plasmotrophy increases the specific productivity of all cells and the functional capacity of organs such as liver and muscle.

Although with the aid of colchicine Dustin's collaborators were able to observe a slight degree of mitoplasia in the thyreotrophically stimulated thyroid, the general appearance of the gland suggests a predominantly plasmotrophic effect; the mitoplasia might in this instance be due to contamination of the thyreotrophic fraction with another pituitary factor having the capacity to engender, perhaps in non-thyroid tissue, a factor mitoplasic for thyroid cells. Such a mechanism would be analogous to the plasmotrophic stimulation of the Leydig cells of the testis to produce steroids, mitoplasic for male genital accessories and perhaps also for germinal cells.



CAMERA LUCIDA DRAWINGS OF FOLLICLES OBSERVED SIMULTANEOUSLY IN A SINGLE OVARY AFTER INJECTION OF COLCHICINE INTO A PREGNANT RAT. × 450.

Although follicle stimulation is an apparent exception to the rule that pituitary substances are mitoplasic only indirectly or not at all, it has been easy to show with colchicine that egg development entails follicular mitoplasia. The mechanism of follicle-ripening is elucidated by the following observations:

(1) After hypophysectomy in the rat, small ova remain small, medium-sized ova persist for weeks, as also do corpora lutea, and large ova become atrophic. No additional primary follicles develop, the medium-sized ones continue to show mitosis for about three weeks, and Graafian follicles showing an antrum degenerate. *The occurrence of follicle mitoplasia between two and three weeks after hypophysectomy is convincing evidence that follicular mitoplasia is not immediately dependent on the pituitary: I assume that it depends on the ovum.*

Ova that are medium-sized at the date of hypophysectomy persist in the production of their mitoplasic factor until such time as they degenerate; in which respect they resemble the cells of the corpus luteum, which persist and maintain pregnancy if hypophysectomy is done on or after the twelfth day of pregnancy in the rat, although their removal before term almost invariably leads to fœtal death.

(2) Five camera lucida drawings (above) of follicles observed simultaneously in a single ovary following colchicine injection of a pregnant rat, illustrate the frequency of mitosis with reference to egg size. In normal and hypophysectomized rats, mitosis begins only when the ovum has more than doubled its initial diameter (more than twenty-five times its initial volume); and the maximum frequency of mitosis occurs at a point when the diameter is five or seven

times (volume about 125–350 times) that of a primordial ovum. After death or expulsion of the ovum, a few mitoses sometimes occur, but mitoplasia soon ceases; the granulosa cells become pyknotic, and wandering eosinophil cells invade the follicle, which degenerates and disappears, or in suitable conditions forms a corpus luteum.

(3) These observations were found to hold good also for the ovary of the mouse, guinea pig, rabbit and dog. Rat ovaries with and without gonadotrophic stimulation were compared in pregnant, normal adult, infantile and hypophysectomized animals. It was consistently clear that pregnancy does not interrupt the follicular mitoplasic activity of medium-sized egg-cells. A large egg-cell failing to produce follicular mitoplasia was occasionally found, but never a mitoplasic follicle without a larger egg-cell.

Conclusion. A follicle-ripening anterior pituitary or anterior pituitary-like factor does not exist.

The pituitary generates an ovotrophic hormone, for which a separate existence from the luteinizing and interstitia-stimulating factors of the gonadotrophic complex is yet undetermined.

The ovum itself produces the folliculoplasic hormone, to isolate which investigation of a suitable technique is in progress. J. Freud.

Histamine and the Action of the Thyroid Gland

In previous investigations[1] we have pointed out that irradiation of white mice with ultra-violet light is accompanied by a loss of body weight. Furthermore, we have noted[2] that there is a relation between the loss of body weight and the function of the thyroid gland. It was possible to demonstrate that the acetonitrile test of Reid Hunt[3] becomes positive during the time in which a lowering of body weight of the irradiated mice was found. Because there is a connexion between erythema-producing power of ultra-violet light and the weight loss, the conclusion was drawn that the formation of histamine-like substances seems to be responsible for the activation of the thyroid gland and the loss of body weight.

In order to test this belief, the following experiments were carried out: histamine hydrochloride (0·01–0·04 mgm.) was injected subcutaneously into white mice five times weekly for fourteen days. The diet of the mice was bread (32 gm. weekly) and water *ad libitum.* The body weight was controlled every week.

We found that it is possible by this means to effect a lowering of the body weight in the injected mice, but not in every case. Apparently, the initial level of the activity of the thyroid gland is important. In those cases, however, where it was possible to obtain a lowering of the body weight, there was also a positive acetonitrile test.

The accompanying table will serve as a preliminary report:

No.	Average body-weight difference between treated and untreated mice	Acetonitrile test for thyroid according to Reid Hunt (Doses 1 5 mgm./gm. body-weight)		
		Surviving 24 hours		
		Histamine treated	Untreated	Result
55	– 6 per cent	7 from 10	2 from 9	positive
58	0	4 from 7	7 from 7	inverse
60	– 3 per cent	5 from 9	4* from 8	positive

* One of these was moribund.

These findings seem to be supported by the findings of Dietrich and Schwiegk[4]. These authors pointed out that injection of histamine produces a higher blood flow in the thyroid gland, as well as in other parts of the circulation, and on the basis of this result a more intense functioning of the gland is understandable.

The observation of a higher degree of activity of the thyroid gland after repeated injections of histamine seems to support further the histamine theory of general ray reactions[5].

Additional data will be published later.

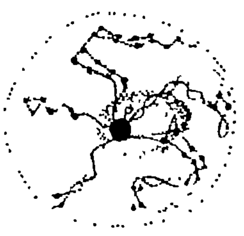
Development of the Giant Salivary Gland Nuclei of *Drosophila*

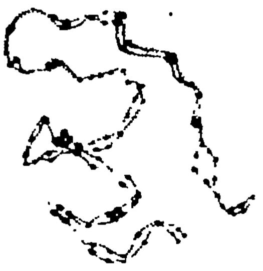
The development of the giant spireme-like salivary gland nuclei of various species of *Drosophila* larvæ (*repleta*, *melanogaster*, *funebris*, *robusta* and *virilis*) has been studied in preparations of whole organs and sections stained after Feulgen.

The nuclei of the salivary glands and other organs of very small larvæ have the structure shown in Fig. 1. The chromocentre is formed at the telophase through the fusion of the heterochromatic proximal ends of the chromosomes. It is situated at the periphery of the nucleus and is always connected with the nucleolus lying in the centre of the nucleus. On the surface of the nucleus are located thread-like paired chromosomes twisted together. Each of these chromosomes consists of two closely connected genonemata. The proximal ends of the chromosomes are united with the chromocentre; owing to this it is possible to determine their haploid number. When the focus is changed a reticulum of the resting nucleus is seen.

The genonemata do not stain after Feulgen and they are well visible owing to the lengthwise arranged



1.



2.

Fig. 1.

A salivary gland nucleus from a small larva (1·5—2 mm. long) of *D. repleta.* ×3200.

Fig. 2.

Two paired chromosomes twisted together. From the cæcum of the midgut of a larva of *D. repleta.* ×3200.

chromomeres. The dimensions and the number of the chromomeres augment with the growth of the larva; the genonemata lengthen and form numerous curves.

The genonemata are uncoiled and straightened with the growth of the nucleus. For this reason, sections of the genonemata including lengthwise arranged chromomeres correspond to single chromomeres of the nuclei of young larvæ. A close contact between homologous chromomeres of two chromosomes twisted together becomes possible and this results in the appearance of bands (Fig. 2).

In a larva 3 mm. long, bands may be noted in all the organs where spireme-like nuclei are found, the chromosomes being at the same time very fine (Fig. 3). Their diameter gradually increases, that is, growth of the chromosomes sets in. After this the number of chromonemata (genonemata with chromomeres and chromoplasma) is doubled and therefore the diameter of the chromosomes also becomes doubled.

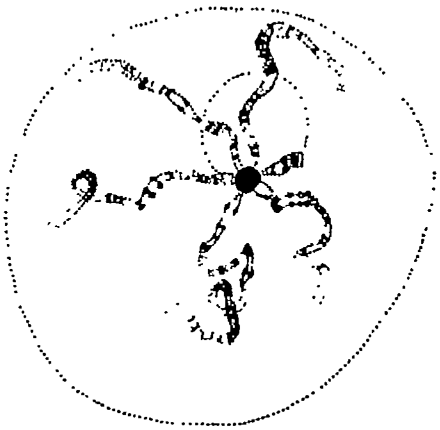


Fig. 3.

A SALIVARY GLAND NUCLEUS FROM A LARVA (3 MM. LONG) OF *D. repleta*. THE PROXIMAL ENDS OF THE CHROMOSOMES ARE CONNECTED WITH THE CHROMOCENTRE. ×3200.

A second duplication of the chromonemata occurs in larvæ of the last age. In the nuclei of the cæcum of the midgut the number of chromonemata is doubled once. In some organs no such duplication is to be noted. In some organs (œsophagus, ring-gland) the spireme-like nuclei are never formed. Here the nuclei as well as the nuclei in different organs of the imago may be compared with definite stages of development of spireme-like salivary gland nuclei. Small nuclei are comparable with the nuclei of very young larvæ, larger ones with those of larger larvæ where the chromosome bands have not yet been formed.

In the present work the identity has been established of the structure of all resting nuclei in the larvæ and imago of *Drosophila* and the absence of any essential difference between them and the spireme-like salivary gland nuclei. This structure of the resting nuclei, that is, pairing of homologues and their connexion with the chromocentre, is retained from the last telophase. This proves the continuity of the chromosomes.

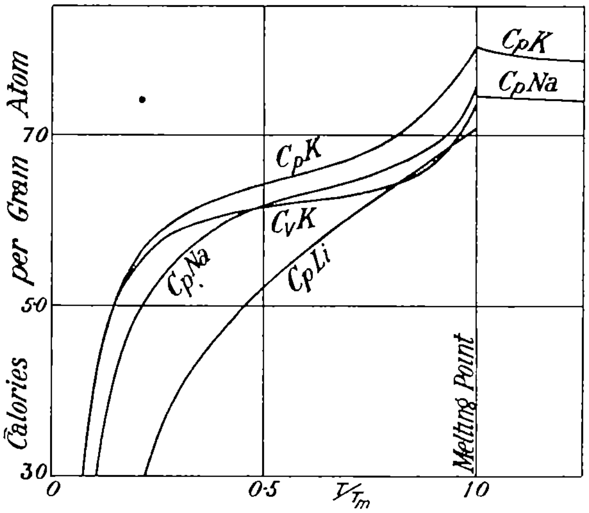
Specific Heat of the Alkalis

IN the alkali metals, the electrons may be considered as degenerate in the Fermi-Dirac sense and incapable of contributing more than a few per cent to the specific heat. The explanation of any effect which exists is therefore probably to be sought in the lattice itself.

We have recently completed measurements of the true (as opposed to mean) specific heat of potassium over the temperature range − 70° C. to + 336° C. and the results show the normal tendency to attain a constant value of the order of $3R$, followed by an abnormal rise of specific heat, setting in at about room temperature and extending up to the melting point (63·4° C.). The potassium was of a high degree of purity and was distilled *in vacuo* into the calorimeter in which the measurements were made. Further, the rate of increase of abnormal specific heat with temperature is of a much lower order than that which impurity should produce, since spurious specific heat due to premelting caused by impurity may be expected to increase as the inverse square of the difference of the temperature from the melting point.

We are therefore of the opinion that the abnormal rise of specific heat is a property of pure potassium.

We have also made some preliminary measurements of the specific heat of lithium over a range of 180° immediately below the melting point. These, combined with the experimental data of others given in Landolt-Bornstein's "Tables" and some values obtained by Bidwell[1], have been used to draw the experimental curve shown in the accompanying graph, on which have also been plotted our experimental values of C_p for potassium, and the C_v values derived from them. The values for C_p for sodium have also been plotted from Landolt-Bornstein; unfortunately, there are insufficient data for rubidium and cæsium.



For the purpose of comparison a common temperature scale, obtained by expressing the temperatures as fractions of the absolute melting temperature, has been used. It will be observed that the abnormal rise of specific heat, extending over a considerable range below the melting point, appears to be a common property of all three elements.

The abnormal behaviour of the specific heat of lithium and sodium has been already noted by

Bidwell[1], who suggests that the abnormality may be caused by a gradual breakdown of the lattice as the melting point is approached. In support of this hypothesis he quotes observations[2] which tend to show that the X-ray diffraction patterns disappear also well below the melting point.

Whatever the cause of the phenomenon, we wish to emphasize that, so far as present knowledge goes, it is an effect which is characteristic of the alkali metals, since it is almost absent in other elements, for example, mercury[3], bismuth[4], iodine[5] and lead[6], on which measurements of true specific heat have been made right up to the melting point.

Free Field Calibration of Microphones

The determination of the 'field calibration' of a microphone, that is, the sensitivity under free space conditions, has been rendered difficult in the past by the presence of air currents comparable with the velocities to be measured, or field irregularities and uncertainties in direction due to reflection from the walls in a small enclosure. If, in the case of a pressure operated microphone, one tries to avoid this trouble by determining the pressure calibration by the resonant tube[1] or thermophone methods and by calculating the increase in sensitivity due to reflection from the microphone, the difficulty, if not impossibility, of making this calculation rigidly for practical forms of microphone is encountered.

We have developed a new technique of calibration by substitution in the free field, using a search tube of small diameter connected to a condenser microphone. The free space calibration of this search tube is obtained by inserting its open end through a rubber bush in one end of a closed resonant tube and adjusting its position until it is one or more half wavelengths from the bush, that is, until it is at a pressure maximum other than those occurring at the two ends of the resonant tube. The search tube is then in a standing wave, which is conveniently measured by a Rayleigh disk suspended at the centre of the resonant tube. We have shown experimentally that the response of the search tube microphone is dependent only on the acoustic pressure at its mouth and is independent of the diameter of the resonant tube so long as this is large compared with the diameter of the search tube. We have been unable to detect any distortion of a sound field from a loud speaker in an absorbent test room due to the presence of the search tube, so it may be used to explore the field before and after the insertion of the microphone to be calibrated. If this microphone has had a pressure calibration in the resonant tube, the increased sensitivity due to reflection can be deduced. A check on this increase is obtained by a comparison of the explorations of the field with and without the microphone present. This has been done and the variation of the '2 : 1 effect' with frequency investigated.

The matter will be dealt with in a paper in the near future.

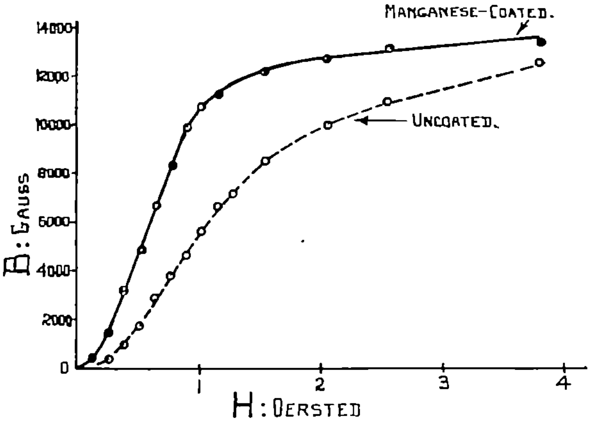
Effect of Manganese Coating on the Magnetic Quality of Iron Wire

A length of Armco iron wire was heated in hydrogen at about 1320° C. until a condition of maximum permeability was reached. The magnetization curve was then obtained (broken line curve in the accompanying graph).

Through the courtesy of Mr. Kenneth Gray, of Messrs. Mellowes and Co., a sample of the same consignment of Armco iron wire was sprayed with a coating of pure manganese powder to a thickness of about 0·002 in. This sample was then heated in hydrogen at about 1320° C. until a condition of maximum permeability was reached. The magnetization curve was then obtained (full line curve in the graph).



This notable improvement of the magnetic quality of iron wire due to a coating of manganese is all the more surprising when it is recalled that the non-magnetic quality of Hadfield's manganese steel is due to a 10–15 per cent manganese content, the maximum permeability of this steel being about 1·2.

Viscosity of Air and the Electronic Charge

From measurements of wave-lengths of X-ray lines with ruled grating and from the Bragg angles of reflections from crystals, it is possible to compute the magnitude of the electronic charge. The value thus obtained by Bearden[1] and Bäcklin[2] is $4\cdot807 \times 10^{-10}$ E.S.U., which is considerably higher than Birge's[3] best estimate of Millikan's oil drop value of electronic charge $(4\cdot770 \pm 0\cdot005) \times 10^{-10}$ E.S.U.

Millikan has in his own experiment[4] assumed a value for the viscosity of air at 23° C. of (1822·6 ± 0·04 × 10^{-7} C.G.S. units, which is based only on the observations of Harrington[5].

Various experimenters have measured the viscosity of air, obtaining results varying from 1820 × 10^{-7} to 1850 × 10^{-7}. In view of the importance of an accurate knowledge of the coefficient of viscosity, we have carried out an investigation on viscosity from flow through capillary tubes. For the purpose of measuring instantaneous values of pressures, a method based on the counting of interference fringes originally adopted by Wagstaff[6] was employed with improvements. Five different capillary tubes were used and various necessary corrections were applied. The final value of viscosity of dry air at 23° C. obtained by us is (1833·3 ± 2·1) × 10^{-7} C.G.S. units, while the increase per degree centigrade is 4·95 × 10^{-7} C.G.S. units. Our value is essentially close to Kellstrom's[7] value (1834·9 ± 2·7) × 10^{-7} and also to Bond's[8] value (1834·7 ± 0·8) × 10^{-7}. Rigden[9] has reported a slightly lower value.

If our value of viscosity of air be substituted in Millikan's oil drop experiment, $e = (4{\cdot}811 \pm 0{\cdot}009) \times 10^{-10}$ E.S.U., which agrees with the X-ray value of $e = 4{\cdot}807 \times 10^{-10}$ within the source of experimental error.

A detailed account of the work will be published elsewhere.

Life-History of the Salmon (*Salmo salar* L.)

IN a recent communication, published in *The Times* of March 26, we appealed to British and Irish boards of salmon fisheries for help in obtaining material for the study of the sexual phases in salmon parr; we now wish to appeal to all European bodies who could send us samples of either salmon parr or salmon smolts five inches in length or more.

We have found that a ripe and almost certainly functional male phase is attained normally in most—and possibly all—male *Salmo salar* from the Welsh and Cheshire Dee before they migrate to the sea as smolts[1]. To obtain evidence of the functionality of this phase it is necessary to examine parr or smolts in the post-breeding season. Material from the Welsh Dee has confirmed the inference that the young males spawn in this river; a full account of this work will be published elsewhere later. It is, however, desirable to investigate the problem throughout the geographical range of the salmon to ascertain whether the phase is constant under widely different environmental conditions.

It is conceivable that breeding habits may vary in this fish with extremes of habitat. The results from the Dee indicate that spent males may behave differently from the mature females of the same age, whence it is advisable to sample different groups or shoals of parr or smolts. Such samples from European countries would be gratefully received and gladly acknowledged by us at the address given below, and reasonable expenses paid.

Revision of Al I Terms

IN the course of a study of the proper co-ordination of the AlH spectral terms to the Al + H atomic combinations[1], some doubts arose as to the correctness of Lansing's analysis[2] of the Al I lines in the region 3050–3070 A. Spectrograms of an interrupted aluminium arc were taken with the large concave grating of this Institute. The measurement of the seven lines (three of which were attributed by Lansing, on the basis of wrong measurements, to an $sp^2\ {}^2D \rightarrow s^2p\ {}^2P$ transition) revealed, first, that no one wave-number difference is equal to the separation of the $s^2p\ {}^2P$ ground state of Al, and secondly, that all the seven observable lines can be explained at once by a $3s3p4s\ {}^4P \rightarrow 3s3p^2\ {}^4P$ transition. This explanation is supported by the analogous term-combinations in the isoelectronic sequence Al I, Si II, etc.[3]; the separations of the multiplet components and relative positions of the two ${}^4P$ terms of Al can be calculated to a rather good approximation from the positions and separations of the related terms. Preliminary results of Zeeman effect experiments on the strongest of the seven lines involved also confirm the ${}^4P \rightarrow {}^4P$ explanation.

The classification, wave-numbers and estimated intensities of the analysed group of seven Al I lines are given in the following table:

		$3s3p4s\ {}^4P$		
		$j = 5/2$	$j = 3/2$	$j = 1/2$
$3s3p^2\ {}^4P$	$j = 5/2$	32700·6 (10)	32604·6 (8)	—
	$j = 3/2$	32776·5 (6)	32680·4 (2)	32624·1 (3)
	$j = 1/2$	—	32727·1 (4)	32671·0 (0)

Since the incorrect previous assignment has been quoted in books of reference (such as "Atomic Energy States" by Bacher and Goudsmit), a revision, that is, the dropping of the term-value of $3s3p^2\ {}^2D$, seems to be necessary. One gains, however, a more uniform co-ordination (in the sense already outlined[1]) of the hydride and deuteride molecular terms of the elements in the third column of the Periodic Table with the proper atomic term-combinations.

An Optical Illusion

In the course of some cinematographic tests, I observed a visual effect which may be of some interest to readers of NATURE and is probably open to a ready explanation.

A cage consisting of two bright wire rings crossing at right angles and about 8 in. in diameter was rotated about its polar axis, at varying speeds. The object was to produce a bubble-like appearance on a film. During rotation three optically black lines appeared, one apparently reaching from pole to pole in a straight line and the other two stretching from pole to pole in right and left hand curves. It is obvious that these dark lines are caused by the passage of the parallels of longitude across each other; thus the vertical line appears when one circle is edge on to the line of sight, and the curved lines when rotation through 45° from that position has occurred.

I should value an explanation of the cause of the lines. It is probably needless to add that they do not show on the cinematograph film. The lines are seen quite distinctly at low speeds—even oscillating the cage with the fingers—and in any light. A spot light and dark background gives the best effect.

Points from Foregoing Letters

S. Kownacki and J. A. Ratcliffe outline a method for investigating 'electron-inertia' effects in thermionic tubes. They point out that if positive ions of atomic mass are used instead of electrons, the frequencies involved are very much smaller and more manageable. They have investigated some 'electron-resonance' effects with tubes in which positive ion emitters were used, and the frequencies involved were about 5×10^5 and 10^6 c./sec. when cæsium and lithium ions respectively were used.

Sir Arthur Keith, after examining a cast of the South African 'Florisbad' skull, concludes that it is an important evolutionary link indicating that South Africa, like Java, has been an independent centre of development from a sub-human form to the modern Bushman and Hottentot.

Prof. C. N. Hinshelwood differs strongly from Prof. Travers in the interpretation of the kinetics of certain gaseous organic reactions, and gives as an example data obtained by Seddon and Travers for the decomposition of acetaldehyde at 400°, from which he would draw quite different conclusions.

An electron-counting device based upon the secondary emission principle has been constructed by Prof. Z. Bay. It does not involve cooling in liquid air to suppress thermal ionization, but utilizes a very thin layer of barium oxide on a nickel base with a high 'work function', and a ten-stage multiplier which gives a ten thousand fold increase. The instrument has a resolving ability which greatly surpasses that of the gas-filled counters.

When negative ions are formed at metal surfaces by bombardment with positive ions, the resulting negative ions need not be of the same element as the bombarding positive ions, according to Dr. F. L. Arnot and C. Beckett. As an example, they describe experiments showing that positive mercury ions may produce negative oxygen ions.

The exchange of hydrogen atoms between secondary alcohols and ketones, or similar compounds, under the influence of ultra-violet light (a reaction important also in the photochemistry of ergosterol) has been investigated by Ch. Weizmann, Y. Hirshberg and Dr. E. Bergmann. They consider that it comes about through the activation of the carbonyl group, CO, which afterwards reacts with the secondary alcohol group, splitting the C—H bond, and giving two free radicals which may either join together or be stabilized by a second oxidation-reduction process.

The fact that mitoses occur in follicles of rats some time after hypophysectomy leads Dr. J. Freud to the view that follicular growth is perhaps only indirectly dependent on the pituitary. It is assumed that the pituitary produces a hormone causing growth of eggs. When the egg volume reaches twenty-five times the original, the production of a hormone by the egg itself becomes apparent by the mitogenic response of the follicle. The folliculogenic hormone is therefore not of pituitary origin but is produced in the egg-cell.

Histamine hydrochloride injected into white mice is found by Dr. F. Ellinger to decrease the body weight in the same way as irradiation with ultra-violet light. He considers that histamine exerts its action by stimulating the thyroid gland.

Several stages in the development of the giant salivary gland nuclei in the fruit fly, *D. repleta*, are described and illustrated by S. L. Frolova. She finds that all resting nuclei in the larvæ and imago of *Drosophila* are alike and do not differ from the spireme-like salivary nuclei.

From new determinations of the true specific heat of potassium and lithium, together with previously known values for lithium and sodium, L. G. Carpenter, T. F. Harle and C. J. Steward have drawn curves showing that the abnormal rise of specific heat, extending over a considerable range below the melting point, is common to these three alkali elements.

A new technique for the calibration of microphones, by substituting in the 'free field' a search tube of small diameter connected to a condenser microphone, is described by A. J. King and C. R. Maguire.

Dr. T. F. Wall finds that the magnetic permeability of an iron wire is notably increased when covered with a thin coating (about 0·002 in.) of manganese.

A redetermination of the viscosity of air by Dr. G. B. Banerjea and B. Pattanaik gives a value of $1{\cdot}833{\cdot}3 \times 10^7$ C.G.S. units, which when introduced in Millikan's data from his oil-drop experiment, gives a value of 4·811 for the electronic charge, in close agreement with the value obtained from X-ray experiments.

Dr. R. Schmid and collaborators have identified in the Al I spectrum a $^4P \rightarrow {}^4P$ transition, which necessitates the dropping of a previously accepted ^2D term.

Research Items

Race and Language in India

WITH a view to possible light on the problem of race and language, Dr. D. N. Majumdar has investigated the physical relationship of certain Austric-speaking tribes of India with special reference to measurements of Hos and Saoras made by himself and others (*Proc. Ind. Acad. Sciences*, 7, 1 ; 1938). The relevant questions to be answered are: (1) Whether the Austric-speaking tribes in India and more particularly the Munda-speaking groups represent the same racial type ; (2) Is there any racial difference between the Mundas and the Dravidian-speaking group ? (3) Are the Hos and Mundas more variable than the Sonthal and Bhumij ? Taking first the comparison of the Ho series from the Kolhan with the Mundas and Bhumij, two neighbouring groups, believed to be of the same racial stock, a comparison of the mean measurements shows that while there are quite marked differences between the three groups, the only significant difference between Hos and Mundas is in stature, while between Hos and Bhumij there is no evidence of difference except for the nasal measurements, which in the Mundas and Bhumij are of doubtful accuracy. Otherwise it is to be concluded that the three groups are of the same or similar origins. Comparison of the Saoras with the Hos and with the Mundas and Bhumij confirms the general belief that the Saoras are of an entirely different stock. Twelve comparable characters show in their means a significant difference in seven, especially marked in nasal length and bizygomatic breadth ; but it is of interest to note that all four types are almost identical as to cephalic index. In regard to differences from the high caste Brahmins and Kayasthas, and the tribal Khasis of Assam, of ten characters, both absolute and indical, significant differences exist between the Hos and Saoras and the caste groups—from the Brahmins in seven and from the Kayasthas in eight, these being interpreted as a racial difference. Between Hos and Khasis there are significant differences in six characters, the difference of the Saoras and Khasis being approximately the same.

Genetics of Schoolboys

IN a study of the stature of 2,500 schoolboys in Sheffield between the ages of 5 and 17 years, Dr. M. A. MacConaill (*Ann. Eugenics*, 8, 117) divides them into three classes: blond, brunet and heterochrome ; the blonds having blue eyes and fair hair, brunets brown eyes and dark hair, heterochromes all other combinations of eye and hair colour. The heterochromes were found to be significantly shorter than the blond and brunet groups at all ages except during puberty. They were also more variable than the blonds and brunets. In explanation of these significant results, it is suggested that the heterochromes are more heterozygous than the other two types. In an earlier paper by MacConaill and Ralphs in the same journal (7 ; 218) a study of the post-natal development of eye and hair colour was made in the same group of schoolboys. The type called leucochrome, with blue eyes and blond hair, showed a steady fall in frequency throughout the age period from 5 to 21 years. All other types were called allochrome, and were divided into brunet, heterochrome and xanthochrome (pure blonds, other than leucochrome). The leucochrome is the type of infancy, from which all other types gradually arise through development of pigment. They fall to a steady ratio of 17 per 1,000 at the age of puberty. It is suggested that the leucochrome type is essentially a Mendelian recessive, the delayed development of pigment in the other types being a manifestation of delayed dominance, as in some animals.

Removal of Poison Glands of Rattlesnakes

PROF. JOHN TAIT of McGill University describes an operation for the surgical removal of the poison glands of rattlesnakes, devised to make the animals more amenable to physiological experimentation (*Copeia*, March 1938, p. 10). The snake is anæsthetized in a glass box containing dilute chloroform vapour and the operation, which is described in detail, occupies at top-speed twenty-one minutes, the depth of anæsthesia being gauged carefully throughout the process. The removal of the glands alters the shape of the head, which becomes narrow like that of poisonous colubrine or innocuous snakes. It has no effect upon the temper or health of the snake nor does it affect the maintenance or successional replacement of the fangs; fang-growth and replacement being apparently controlled independently of the associated poison glands. Another point of interest was that in one or two of the early trials the poison sac was perforated and venom flowed freely into the open wound; the poison was swabbed away so far as possible, but in no case did the snake show any harm from being deluged with its own poison. The procedure devised for deglanding should prove a useful advance, for it produces a wound that heals readily, no case of lethal sepsis having been recorded in operations on some hundred and twenty snakes. On the other hand, the old method of removing the fixed and reserve fangs usually resulted in an infection of the mouth, which was intractable to disinfection and resulted in death.

Development of Compound Eyes

AN important work upon the morphogenesis of the compound eyes of arthropods, by Francis Bernard, has been issued as Supplement 22 to *Bull. Biol. France et Belgique* (1937). In spite of differences in the minute structure of the elements of compound eyes, there is a common plan in their development and growth. Thus the development of parts follows a regular succession—optic ganglia, retina and peripheral pigmentary cells, cornea and crystalline lens. So in the growth of compound eyes—a subject little studied hitherto—Bernard finds that increase in size is due to additions of new elements or ommatidia formed in a lateral hypodermic zone. The elements do not reach the surface and become functional until two or three stages after the cell-divisions which originate them. The additional facets grow in regularly rhythmic series parallel with the stages of moulting, except in the crab, *Macropodia rostrata*, where phases of arrested development have been observed. Finally, the author devotes a chapter to the study of the structure of reduced compound eyes, adding twenty new examples from his own observation. Reduction in the adult eyes is due to three distinct processes: simple atrophy or arrest of normal development as in the retina of all arthropods studied and in the crystalline cones of insects; hypertrophy of certain secretions, as in the rhabdome of all arthropods, and the cones of Crustacea; and degeneration in the course of larval life, as in the optic ganglia of certain parasitic Crustacea. This comprehensive study should facilitate new researches on the subject of morphogenesis in compound eyes.

Dextrality in *Limnæa peregra*

The inheritance of dextrality and sinistrality in snail shells has been shown to be a phenomenon of considerable complexity with several peculiar features. The problem has been carried further in a long paper by Capt. C. Diver and I. Andersson-Kotto (*J. Genetics*, 35, No. 3). It has already been shown in *Limnæa peregra* that four types of broods exist: *A* broods, all dextral; *K* broods, all sinistral; *E* broods, sinistral with a few dextrals; and *F* broods, dextral with a few sinistrals. Sinistrality is also a simple recessive to dextrality, but owing to the nature of the character, it is determined in the egg before fertilization by the joint action of the genes in the zygotic constitution of the parent. The constitution of an individual is therefore determined by the brood it produces, and segregation is only visible in F_3. *E* broods are genetically sinistral, but contain up to 20 per cent of phenotypic dextrals, the percentage varying in different strains. On the other hand, the sinistrals produced in *F* broods are usually genotypic as well as phenotypic. These and many other results of breeding experiments are explained on the hypothesis that *E* broods are the product of a series of modifying genes, some stronger in effect than others, which convert a homogeneous sinistral brood into a mixture. They follow the system of delayed inheritance, like the principal gene. The *F* broods are probably of different types, some of them due to a direct mutation from dextrality to sinistrality.

Action of One Plant Upon Another

A short paper by Prof. F. E. Weiss (*J. Roy. Hort. Soc.*, 63, Pt. 4, 166–169, April 1938) directs attention to an interesting trend of modern botanical research, namely, the influence of one plant upon another. Relations between stock and scion, and between two symbionts are obvious instances, but there are also less patent influences. Prof. Weiss considered the work of Gurwitsch on mitogenetic rays, where the proximity of one plant has been held to induce cell division in another organism. Toxic substances released from one plant may inhibit the growth of another, and it is probable that the grass under the trees in some orchards has a deleterious effect upon the fruit crop. Ripening apples liberate a substance, probably ethylene, which can assist the maturation of later varieties, and also, according to Gane and Smith, can affect the germination of peas deleteriously. The late Prof. Molisch had experimented further in this direction, and found that very light doses of apple vapour assisted the germination of many kinds of seeds, where heavier applications were harmful. Leaf-fall in privet, elder and other plants was induced by the emanations from apples, which also stimulated the rooting of poplar and willow cuttings. Vapours from pot-bound roots of *Melaleuca squamea* and *Acacia verticillata* accelerated the growth of vetch seedlings. It is obvious that more research is desirable, but the results collected by Prof. Weiss offer a most attractive field for future investigation.

A Virus and its Insect Vector

Some ingenious experiments upon the relations between Hyoscyamus virus 3 and the aphid *Myzus persicæ* are described in a recent paper by Mrs. M. A. Watson (*Proc. Roy. Soc. B.*, 125, 144–170, March 1938). Relations between a virus and its insect vector are often very close. The paper under review shows that the aphid can transmit the virus much more easily if made to fast before feeding upon infectious material. Previously fasted aphids, when fed for one hour on healthy plants before their diet was changed to infectious material, however, transmitted the disease no better than unfasted ones. Unfasted aphids quickly lost their power of infecting, whilst fasted insects retained this ability for a longer time. A consideration of these points leads to the supposition that the virus is inactivated by some substance acting during the digestion of food. Trypsin is known to inactivate the virus *in vitro*, and since this enzyme is not produced when an aphid fasts, the assumption that it acts as a substance toxic to the virus fits all the above facts. It is not yet clear, however, how such inactivation by a stomach enzyme could exert an effect through the salivary glands and proboscis, which are regarded as the organs of re-infection.

New Map of Graham Land

The map of Graham Land, Antarctica, was considerably changed as the result of Sir H. Wilkin's flight ten years ago. Now as the result of the air and sledge journeys of the British Graham Land Expedition under Mr. J. Rymill, some of the older features of the map have been reinstated but with modification. The new map appears in the *Geographical Journal* of April and May accompanying an article by Mr. Rymill on the work of the expedition. The peninsularity of this part of Antarctica is again established. Casey Channel and Stefansson Strait disappear. Scripps Island, in about lat. 70° S., is a mountainous area of the mainland. But a remarkable new channel appears on the map. King George VI Sound, twelve to thirty miles in width, stretches for more than two hundred miles between the mainland of Antarctica and Alexander I Island. The latter is much increased in size and appears to be linked by shelf ice, probably of glacier origin, with Charcot Island farther west. The sound is filled with ice and was explored by sledge and aeroplane. At the most southerly point reached in about lat. 72° S. there was no sign of a channel to the east. The sound turned in a south-south-west direction and widened considerably, suggesting that it opened into a wide bay south of Alexander I. Island. The lack of a good route eastward towards the Weddell Sea prevented the exploration of the inaccessible western coast of that sea, which had been one of the main objectives of the expedition.

Cyclone Season 1934-35 at Mauritius

No. 17 of Miscellaneous Publications of the Royal Alfred Observatory by M. Herchenroder, entitled "The Cyclone Season 1934–35 at Mauritius", contains charts and descriptions relating to the eight cyclones of that season with some reference also to five minor disturbances. The season was not a remarkable one, the number of cyclones and minor disturbances being the same as in 1933–34, except for the absence of cyclones around Mauritius and Madagascar in March and for the lack of evidence of any such storm throughout the entire season around the Cocos Keeling Islands. The author, in reference to a common notion that tropical cyclones are not accompanied by high pressure systems as is the case with intense temperate depressions, notes that five out of the eight here described disproved this notion in a striking manner. Four of these formed near Madagascar, and the accompanying anticyclone was easily identified with the aid of the South African weather reports. The incursion of this anticyclone north-eastwards into lower latitudes with the invasion of cooler air from higher latitudes appeared to be a preliminary event incidental to the formation of the tropical cyclone centre. It is suggested that perhaps only lack of information prevents a similar state of affairs from being demonstrable in the case of the formation of tropical cyclones in other parts of the South Indian Ocean. This lack of information, it is suggested, is unlikely ever to be got over by reports from ships alone. Attention is directed also, in this discussion, to another matter in connexion with the development of these cyclones, and that is the growing belief among observers that a necessary condition for such development is the extension of the cold easterly or south-easterly current of the accompanying anticyclone above the equatorial current, a belief referred to, for example, in the meteorological report of the Madagascar Weather Service for March 1935.

Effect of the Surrounding Medium on Fracture in Solids

P. Rehbinder and E. Wenstrom (*Bull. Acad. Sci. U.R.S.S.*, 548 ; 1937) have shown in previous publications that 'brittle fracture' of solid bodies becomes easier on immersion in a suitable liquid, and that the surface hardness is reduced by this immersion. This phenomenon is connected with the reduction in surface energy produced by immersion. In the present work they show that the *plastic* fracture of wires stretched under a non-polar liquid (pure hydrocarbon oil) is greatly influenced by the addition of polar substances. For example, the time during which plastic flow takes place before fracture in lead may be reduced by a factor of 30–60 by the addition of 0·001–0·005 per cent of $C_{25}H_{51}COOH$. This effect is described as an 'internal lubrication' of the metal, and it is suggested that it plays an important part in the action of lubricated cutting tools.

Absorption of Fast Electrons

A. J. Ruhlig and H. R. Crane (*Phys. Rev.*, 53, 618 ; 1938) have extended the work of Crane on the energy losses of high-energy electrons in thin lead sheets. The particles studied included a group 0·35–1·35 M.e.v. from radioactive phosphorus and a group up to 17 M.e.v. produced by the Li + ^{1}H gamma-radiation. In the lower energy region, the losses due to radiation are negligible according to the Bethe–Heitler theory, and the loss is due almost entirely to ionization processes. The experimental value for the energy loss is about three times that given by the theory of Bloch, and shows an increase on going from 0·5 to 1 M.e.v. which is difficult to understand. In the high-energy group the energy loss is primarily radiative, and follows theory in a general way. The experimental values are appreciably higher than the theoretical.

Accuracy of Parallaxes

In a recent paper, Prof. W. J. Luyten shows that parallaxes determined from spectral class and proper motion possess a high *individual* accuracy, contrary to the generally accepted view that they are useful only for statistical investigation (*Mon. Not. Roy. Astro. Soc.*, 98, 5, March 1938). In 1923, the author published the spectra and hypothetical parallaxes for 100 stars of large proper motion, and in 1924 he published a list of hypothetical parallaxes for bright stars in the southern hemisphere. When these lists appeared, only a small proportion of the stars had known trigonometric parallaxes, but these have been determined for practically all of them since. Two tables show the comparison between parallaxes predicted and those determined trigonometrically, and the agreement is as good as we find between two different series of trigonometric parallaxes. There are a few cases where considerable discrepancies appear, but it is suggested that the spectral class used is wrong for three stars in the first list, and in the second list, taken from *H.C.*, 252, 1924, *p* Eridani, which shows a fairly large discrepancy, is an exceptional star, having a tangential velocity of only 8 km./sec., and a much larger mass than the mean for its spectral class. The author is of opinion that if accurate spectral classes, magnitudes and proper motions were available, it would be possible to predict the parallax of a star with a mean error of 23 per cent, corresponding to mag. 0·7 in the resulting absolute magnitudes.

Czech Astronomical Observations

Memoirs Nos. 3, 4 and 5 recently published by the Czech Astronomical Association at Prague give, respectively, results of solar observations, observations of variable stars, and the results of the expedition to Sara, U.S.S.R., to observe the total solar eclipse of June 19, 1936. The solar observations, which were carried out by nine of the Society's members, express the sun's activity during 1935 as given by sunspots, faculæ and prominences. Using a direct-vision spectroscope and the *H*α line of the solar spectrum, the height of the chromosphere was also systematically determined around the disk. The variable stars discussed are RY Bootis, ST Camelopardalis and R Scuti, which have been regularly observed by members of the Society since 1930. R Scuti is shown to have a variability which places it in the RV Tauri type, that is, an irregular variable resembling to some extent a Cepheid, with a range of about two magnitudes and a variability in spectrum. The solar eclipse expedition included in its work (*a*) a study of the height and intensity of the chromospheric lines of the flash spectrum using the moving plate method ; (*b*) the distribution of radiation at 0·56 μ over the solar disk ; (*c*) the sky spectrum during totality ; and (*d*) a photometric study of the corona in the infra-red. The results are a useful quota to knowledge of the sun obtained under the rare conditions of a total eclipse, whilst the intensity determination of radiation across the disk affords an interesting comparison with the extensive observations made by Abbot some years ago without an eclipse.

The National Physical Laboratory

Report for 1937

THE report of the work carried out at the National Physical Laboratory during the year 1937 shows marked activity in each of the seven departments into which its field of operations has been divided and also in connexion with the special work of the William Froude Laboratory on the propulsion of ships[*]. One aspect of the report which should not be lost sight of in its perusal is the indication, which is implicit on practically every page, of the value of the assistance it can give to industry both in the results of its own wide programme of research and also in its readiness to undertake special investigations on behalf of manufacturers. This should be more widely known and appreciated as the scope of their work and the amount of scientific data accumulated place the staff in a quite unique position to offer advice and help.

In the Physics Department, investigations on the thermal conductivity of several gases, liquids, and solids have been proceeding. These have included a survey of published data regarding the thermal and electrical conductivities of iron and steel with results which have indicated the direction of the further investigations which are being undertaken. Research has been carried on in connexion with the thermal insulation of buildings, refrigeration, and properties of metals at high temperatures. The investigation which has been proceeding on the International Temperature Scale is now completed and the report summarizes its results in relation to the standard platinum, 10 per cent rhodium-platinum thermocouple used in the region between 660° and 1063° C. and the conditions which limit its accuracy. The Radiology Section, among many other investigations, continued the study referred to in the previous report on the fatigue failure of metals. The examination of annealed mild steel has been completed and has shown that when the applied stress is such as ultimately to produce fracture, severe fragmentation of the crystallites occurs and increases up to the point of fracture. Where fragmentation has already been carried to an advanced stage by severe cold work, it has been found that, provided the stress applied is below that necessary to produce eventual fracture, no further structural change occurs.

The value of the work of the Electrical Department has received recognition by the acceptance of the results of the investigations on units and standards. Also a new clock has been devised and constructed at the Laboratory which is of such a high degree of accuracy that its error is but a fraction of a second in a year. This has been attained by mounting the quartz ring oscillator on three fixed points as supports located at the nodes of the vibrating ring. This provides a more robust form of construction which makes it practically independent of mechanical vibrations and changes of level and so constitutes it a practical instrument for use in astronomical observatories, in radio-telegraphy, etc. In addition to the clock made for the National Physical Laboratory, one has also been made for the Royal Observatory, Greenwich, and two are being made for the Australian Government for use in connexion with radio communication. The work on visual characteristics has led to a number of interesting results, some of which are of direct importance in photometry and in practical problems of lighting. A paper published by the Department gives a full account of the work done on non-foveal vision, the visual conditions which supervene when the sensitivity of the eye is reduced by the presence of a source of high intensity in the field of view. In relation to the detection of objects in an artificially lighted street, the relative merits of lights of different spectral distributions have been studied. This work, in progress, is on the lines of ascertaining the average time taken by different observers to detect models of a person or a dog introduced into a film projection under conditions simulating those existing in typical carriageways.

Among the new researches commenced during the year in the Engineering Department is an investigation on the welded construction of pressure vessels. Developments in chemical engineering have led to a big increase in the use of liquefied gases, and for transport it is of considerable importance that, without sacrificing the necessary margin of safety, any improvements which result in reduction of weight should be investigated. Other new researches deal with the surface finish of steel strip—a matter of special importance to the aircraft industry—experimental work on the properties, in particular the variation of liquid density and of vapour pressure with change of temperature, of the gases propane and butane, and also an investigation into the silencing of motor cycles.

The use of cast materials for engine crankshafts is a recent unexpected development. In co-operation with the Institution of Automobile Engineers, the British Cast Iron Research Association and five interested firms, one steel material and four irons were fully investigated and the conclusion of the inquiry is recorded. These materials were subjected to static, hardness, and impact tests and also to a comprehensive series of fatigue tests involving bending, torsion, and combined bending and torsion. Metallurgical examination included chemical analysis and microstructure. Under the combined fatigue stresses these cast metals exhibited characteristics sharply dividing them from the ductile wrought steels. The results have been published separately and give a lead as to the wide possibilities of application of these cast metals in the field of engineering.

The Aerodynamics Department has been working at high pressure particularly in connexion with development work on new types of aircraft. The analysis of turbulent flow by determination of the turbulent energy in various frequency bands has been continued. So far as this work has gone, it has proved of exceptional interest, and the agreement found with the modern theory of turbulence indicates that there is every hope of understanding turbulent phenomena much more fully in the near future. Airscrew research has been carried out in co-operation with the Royal Aircraft Establishment on full-scale airscrew performance in the 24-ft. wind tunnel there. On the subject of 'flutter derivatives' it is hoped that some light will be thrown by the results of measurements of the instantaneous air forces acting on oscillating aerofoils by an apparatus which is under development.

---

[*] The National Physical Laboratory: Report for the year 1937. Pp. iv+150. (London: H.M. Stationery Office, 1938.) 2s. 6d. net.

Among the researches carried out at the William Froude Laboratory was one for the Herring Industry Board and the Coal Utilisation Council concerning the herring drifter, and it was shown that the form of hull in use at present can be so improved as to give a 40 per cent reduction in power for a speed of 9 knots, with a definite improvement in seaworthiness as shown by tests in rough water. In the Alfred Yarrow Tank it is proposed to replace the wave making apparatus which after twenty-one years service is badly deteriorated. The new equipment will be of 12 b.h.p. instead of 7 b.h.p. and will, by being run from a separate electric supply, be able to give a longer test. Numerous researches have been carried out on screw propellers and in several cases the results have been published. Other researches have been in connexion with the shape of ship bows, natural frequency relative to ship vibration, and the effects of helm action on propulsive efficiency. For a special tug, a programme of research on a pair of paddle wheels will shortly be put into operation.

These are but a selection of the activities which are treated in the report, in which particulars of the several papers published by each of the departments are given.

Nutritional Surveys of Inland Australia

Problems of Child Nutrition

FEW of the various national nutrition committees appointed following the recommendations of the League of Nations have brought more enthusiasm and resource to their task than the Commonwealth of Australia's Advisory Council on Nutrition. Its recently published fourth report provides ample evidence not only of painstaking endeavour to arrive at a true assessment of the nutritional state of white children living in urban and rural districts of Australia, but also of the need for devising means whereby the revealed deficiencies may be corrected.

Dr. F. W. Clements, who is engaged on a three-year programme of surveys designed to cover a large section of the interior mainly beyond the railway system, presents his preliminary findings for certain inland areas of Queensland, New South Wales and Victoria. Of the children examined in New South Wales, 23·7 per cent showed signs of unsatisfactory nutrition; in Queensland the figure was 18·8 per cent, and in Victoria, 13·3 per cent. Amongst pre-school children of Melbourne examined during the same period, the corresponding percentage was as high as 21·7. Although the numbers examined were necessarily small, there is no reason to suppose that they were in any way selected or unrepresentative of the prevailing conditions. The Council, therefore, finds itself faced with two distinct problems, the undernourished child of the city, and the undernourished child of the remoter outback districts.

Chief consideration has been given to the occurrence of rickets and nutritional anæmia, the incidence of both of which was found to be considerable. In Victoria, for example, a high incidence of anæmia among pre-school children was discovered, boys apparently being more prone to develop the symptoms than girls; and the conclusion is reached that the average hæmoglobin level in children of the Queensland outback is distinctly lower than that of children living in the cities of Scotland. A careful watch for scurvy was unrewarded save for one doubtful case of hypertrophic gingivitis. That fruit is rare may be gathered from one of those touches of significant observation which make this whole report of unusual interest. At a backwood's race meeting the author purchased from a wandering salesman a dozen small shrivelled apples at a cost of 2½*d.* each. Fresh tomatoes are also a luxury, but potatoes and pumpkin are largely eaten. Further inquiry into the circumstances of those children found to be suffering from rickets, elicited the fact that they were accustomed to a low intake of protective foods, little milk and no cod liver oil. It is reported, too, that in several towns no milk is available for the feeding of children in infancy.

The section on the Mount Isa communities is perhaps the most interesting in the report. Here, two almost distinct towns have grown up around the Mount Isa lead-silver mines. At the mine site the enterprising company has built for its employees comfortable houses adequately planned and situated amid sylvan surroundings. Rent is reasonable, electricity is free, and many other advantages play an important part in maintaining a sense of citizenship. On the town side, on the other hand, are to be seen shacks improvised from carbide drums, kerosene tins and hessian, where a shiftless and improvident population has no incentive to maintain a decent standard of living. The following reflects the difference in condition, and it is to be noted that the parents of children suffering from rickets in the Mines School were all new arrivals to the district and had been long unemployed.

Deficiency Diseases	*Town School*	*Mines School*
Nutritional anæmia	12·0 per cent	3·4 per cent
Active Rickets	17·0 ,,	10·3 ,,
Chronic infections	4·0 ,,	1·7 ,,

In view of their importance and bearing on similar problems being investigated in other parts of the Empire, it is to be hoped that these Australian results will be placed on permanent record and be made easily available to all who are engaged on nutrition survey work.

International Conference for the Protection of the Fauna and Flora of Africa

THE Second International Conference for the Protection of the Fauna and Flora of Africa was opened by the Marquis of Dufferin and Ava, Parliamentary Under-Secretary of State for the Colonies, in the Moses Room of the House of Lords on May 24 and was attended by Government delegates of the Union of South Africa, Belgium, Great Britain and Northern Ireland, Egypt, France, Italy, Portugal and the Netherlands. The interests of the Anglo-Egyptian Sudan were represented by the United Kingdom and Egyptian delegations jointly. The main object of the Conference was the exchange of information and exploratory discussion preparatory to a further conference, which it is hoped to hold in 1939. The Earl of Onslow presided, and subsequent meetings were held on May 25 and 27. A committee of experts was appointed to draw up a list of suggestions for addition of further species to the Annex of the Convention.

It was announced that the Convention, signed in 1933, had been ratified by the United Kingdom and Belgium in respect of their African territories, and by the Union of South Africa, Egypt and the Sudan, and that it was hoped that France, Italy and Portugal would shortly be able to complete their ratifications. During the course of the meeting, the French delegate announced that he had just received information that the President of the French Republic was at that moment on the point of signing the ratification of France.

The proceedings opened by the submission of statements by delegates of action taken by their respective Governments since the signing of the Convention of 1933. The High Commissioner, Mr. C. T. te Water, on behalf of South Africa, stressed the necessity of arousing public interest and stimulating effort for the protection of wild life, and pointed out that international conferences such as the present one help greatly in bringing to the attention of the Governments concerned a subject of great national importance. He stated that his Government is continuing its policy of setting aside areas as game reserves and national parks, and since the Convention had come into force, further legislation has been promulgated for the preservation of fauna and flora. He alluded to the serious condition of the status of the mountain zebra (*Hippotogris zebra*), which is slowly dying out, and said that the matter is being given close consideration by the Government in order to secure measures for the adequate protection of the remaining herds, and that land is being acquired in various districts to this end. He also mentioned that the laws with regard to shooting game from motor-vehicles are very strictly carried out.

The Belgian delegation reported the creation of further national parks and stated that an important feature of the administration of these parks is the undertaking of systematic exploration of their fauna and flora, with special reference to the presence of disease, particularly parasitic disease, among the animals contained therein. The Government has taken measures for the protection of flora by setting up forest reserves in which special attention is given to the need for maintaining an adequate water supply.

Sir William Gowers, Senior Crown Agent for the Colonies, in presenting the report of the United Kingdom, directed attention to the great diversity of conditions in the fourteen territories concerned, and their difference in range of flora, fauna and density of population. The establishment of reserves is the policy of many Governments, but, while it is not regarded as incompatible with the principles of the Convention that a national park should be inhabited by natives, it is nevertheless regarded as important that the extent of native population should not be such as to interfere on one hand with the rights of the natives and on the other with the interests of game preservation. It has therefore been necessary to proceed with caution before definitely demarcating areas to be set aside as national parks. In pointing out the salient features of the report, Sir William Gowers mentioned the action being taken by the Tanganyika Government in establishing a national park on the Serengeti Plains, the steps taken by the Government of Nyasaland to set up a strict natural reserve in its territory, and the proposals under consideration for similar measures in Kenya, Nigeria and Sierra Leone.

Mr. F. B. Wright, Acting High Commissioner for Southern Rhodesia, reported the establishment of four game reserves and emphasized the interest felt by his Government for the objects of the Convention.

The Italian delegate stated that a special scientific mission has been sent to Italian East Africa to undertake a full survey of the position with regard to fauna and flora, and that the results of this investigation will be communicated for circulation.

The Portuguese delegate in presenting his report put forward two suggestions ; first, that the question of surrounding animals by fire for hunting purposes should be examined again on account of the harm which this causes to fauna and flora ; and secondly, that the possibility of taking measures for the partial and progressive modification of nomad native agriculture in African forests, in order to avoid the frequent and irregular clearing of important tracts of forest land, should be considered.

Statements were also given by the Egyptian, French and Anglo-Egyptian Sudan representatives, and the Netherlands delegate stated that his Government is greatly in favour of the Convention and has already applied Article 9 (concerning the traffic in 'trophies') to the Dutch East Indies.

A discussion on the subject of vermin took place and it was agreed that a positive definition of this is impracticable. Mr. te Water suggested that all Governments concerned be asked to furnish memoranda showing action taken in their respective territories to deal with this problem.

The question of (*a*) the exchange of information relating to infectious or contagious diseases of importance for the preservation of fauna or flora, or capable of affecting man as well as animals and, (*b*) the exchange between Governments of lists of persons known to have been guilty of persistent infringements of game regulations, were both examined at length, and the conclusion reached that with regard to both these questions a centralized system of exchange of information is desirable, and that recommendations to this end should be put forward.

The report submitted by the Committee of Experts as to species recommended for inclusion in the Annex of the Convention on the occasion of its next revision was accepted. This contained proposals for the transference of certain species mentioned in the Annex from Class *B* to Class *A*, thereby affording them greater protection, and included among others the giant eland (*Taurotragus derbianus* (Gray)), black rhinoceros (*Rhinoceros bicornis* Linnæus) and secretary bird (*Sagittarius serpentarius serpentarius* Miller). The report also suggested the inclusion in both classes of certain species not heretofore included in the Annex. For inclusion in Class *A* were recommended among others the red wolf (*Canis simensis* (Ruppell)) and bongo (*Boocercus eurycerus* Ogilby) and the African peacock (*Afropava congensis* Chapin), so recently discovered to science, northern secretary bird (*Sagittarius serpentarius gambiensus* Ogilby), African broadbill (*Pseudocalyptomena graueri* Rothschild), Abysinnian ground chough (*Zavattariornis stresemanni* Holtoni), the flightless rail of Inaccessible Island (*Atlantisia rogersi* Lowe) and the so-called fishes of the grottoes of Thysville, African species of the genus *Cæcobarbus*. The last-named was the only case for the protection of fish brought to the attention of the Committee. The species being blind and of great zoological interest, it is the opinion of the Committee that it should receive as complete protection as possible.

The Conference agreed to recommend that a further meeting be held in London in 1939, concurrently with the meeting of the proposed International Conference for the Protection of Fauna and Flora of Tropical Asia and the Western Pacific. On the proposal of Mr. te Water, it was agreed to express the hope that it would be possible for the Governments concerned to arrange for the attachment to their respective delegations of officers in charge of the principal national parks, such as the Kruger National Park, and the Parc National Albert, whose expert advice would greatly assist the work of the Conference.

Impact of Chemistry on Biology

THE forty-second Bedson Lecture was delivered in the Chemistry Lecture Theatre, King's College, Newcastle-on-Tyne, on May 19 by Sir Henry Dale, who spoke on "The Impact of Chemistry on Biological Science". Sir Henry pointed out that the two sciences of biology and chemistry were developed during the nineteenth century independently of each other; tremendous advances have been made in more recent times as the two subjects have become closely interwoven into the science of biochemistry.

Since the end of the last century, organic chemistry has developed along two main lines: (1) the synthesis of new substances of little direct relation to biological science, and (2) the isolation and identification of substances from 'vital' chemistry. Progress has been slow in the chemistry of the animal body, and the lag between chemical recognition and the assignment of a definite biological function to compounds isolated is well exemplified by the fact that although creatine was isolated from muscle in 1832, it was not until 1927 that a definite role in muscle metabolism was assigned to this substance.

The comparatively new science of bacteriology had its origin in the work of Louis Pasteur, an organic chemist whose interests developed along 'biochemical' lines until he eventually became a complete biologist.

The investigation of protein chemistry by Sir Frederick Gowland Hopkins which led to his attempt to make a 'perfect' diet by mixing the correct amounts of fats, carbohydrates and proteins gave rise to one of the most sensational discoveries in recent years, the vitamins. In a very short time, many of these compounds have been not only isolated, but also in some cases have been assigned a definite chemical formula which has been proved by synthesis.

Several enzyme actions have recently been investigated from a chemical point of view, and it seems extremely probable that enzyme and coenzyme phenomena will shortly be explained as chemical actions, closely connected in some cases with the vitamins.

The discovery of the natural stimulants formed by the animal body, the hormones, has opened up an important new field of biochemical research, in which great advances have already been made. Several of these compounds have been isolated and synthesized, such as, for example, thyroxin and adrenaline, and the sex hormones have been shown by synthesis to be closely connected with inert sterols present in animal tissues.

Finally, even the transmission of nerve 'messages' has been shown to involve reversible physicochemical changes in which simple organic compounds play a part.

Pre-Roman Provence

EARLY in April of this year, it was announced that archæological discoveries, which are of no little importance, had been made near Saint-Rémy, a small town a few miles from Arles in Provence. Provence, the original 'Provincia' of Rome's extra-Italian expansion, is rich in monuments, which, if Roman in origin, are none the less Greek in spirit and conception. This is a legacy from the Greek colonists from Phocaea, who founded Marseilles about 600 B.C. and extended their influence over the whole region, which was later to be known as "The Province". Intermarriage with the natives left an indelible mark on the physique of the population, more especially to be seen in the beauty of the Provençal women.

Although the district around Arles was termed "Grecia" until the fourteenth century, little is known that is of purely Greek culture, nor has it been determined with precision how far and to what degree Greek influence pervaded the country. The importance of the results of recent excavations lies in the fact that they have brought to light remains belonging to the pre-Roman period, as well as evidence pointing to the measure of fusion with native culture.

At Saint-Rémy, which possesses two theatres of the Roman period, both Greek and Roman constructions beside a tile-covered canal have been found near a Roman road, triumphal arch and tomb dating from the first century, and beneath a Roman wall. Fifty-two altars of local stone and marble were dedicated to either the god Sylvanus or the goddess Cybele. The foundations of an entirely Greek house were uncovered, in which twelve rooms are seen to have opened into an *atrium*, in which the bases of four columns are still visible. Baths of the time of Augustus, measuring forty-seven yards by thirty-five yards, were found. Into these, water flowed through a huge sculptured head. A large amount of Greek red-on-black pottery was found with forty-four small votive lamps and a magnificent rock crystal ring, ornamented with a woman's head.

Further discoveries in these excavations are now announced. According to a dispatch from the Paris correspondent of *The Times* in the issue of May 23, while most of the walls which have been found belong to a large Roman construction, the architectural remains of pre-Roman date are also important. A pillar with egg and astragalus pattern is of second-century Greek style, while column heads, probably pointing to Italian models, are evidently the work of competent masons of Greek training. The gargoyles, however, are the rustic Celtic versions of classical gargoyle lions. It is thought that they belong to a building, possibly a temple, of Greco-Celtic style.

Further evidence of cultural fusion comes from Glanom, a small Celtic *oppidum* near Saint-Rémy, where in a large necropolis graves containing Celtic and local Hellenistic pottery have been excavated by M. de Brun, keeper of the local museum. The tombs, it is stated, are marked by tall pillars, on which Celtic names are inscribed in Greek character. The cemetery is dated in the period of the Roman occupation at the end of the second century B.C. Still earlier evidence comes from Roquepertuse, where the Count de Gerin-Ricard, keeper of the Musée Borely at Marseilles, has excavated a sanctuary of the fourth century B.C. Here he has found what is described as a curious mixture of native and Greek taste. The pillars supporting the entablature are decorated with the heads of slain enemies, the horses on the frieze are of the barbarian type, while the double heads affixed to the architrave are a successful and attractive blend of Celtic and Greek elements.

Antarctic Plankton*

EXACT systematic work is essential for oceanographical plankton studies, since we must know the species with which we are dealing before we can use them in any practical way. Mr. Hendey's extensive monograph on the diatoms of the Southern Ocean is most useful and is a careful study entailing a large amount of labour. With so much material it has been possible to review the inside variation present in most groups and in the individual species. The interesting fact is clearly brought out, agreeing with Wimpenny (1936) that the diatom frustules in cold water are smaller, thicker-walled and more vigorous than those from warmer waters, the reverse of what is known to exist in many marine animals. The holoplanktonic flora of the cold water from the oceanic habitats forms the major part of the collection and consists of a small number of discoid and a large number of filamentous pennate forms. The author, however, in his classification discards the usual division into Centricæ and Pennatæ, and his method of regarding many so-called species and varieties as "phases" of one species reduces considerably the number of species recognized. Thus, to take one example, *Corethron* according to Hendley is a monotypic genus, *Corethron criophilum*, much discussed by many workers, being the only species with many phases. This at least tends to simplify matters, and a reduction of the ever-increasing number of species is all to the good.

Most of the diatoms of the Southern Ocean have a wide distribution and can tolerate a great variation in the conditions of their environment, but it is found that *Rhizosolenia curvata* Zacharias has a very limited range, being a typical sub-antarctic species occasionally spreading into Antarctic waters. Dr. Hart in his paper on this diatom shows that it forms a valuable indicator of the southern limit of sub-antarctic surface water. It has always been recognized that this surface water is frequently forced some small distance south of its normal limit, the Antarctic Convergence, and it has been possible to prove that *R. curvata*, an easily recognizable and characteristic form, is always in the plankton whenever it has been possible to show such southward movement hydrographically.

The seasonal circulation of the Antarctic macroplankton is dealt with by Dr. Mackintosh. Amongst other interesting facts it is shown that certain species which are usually regarded as inhabitants of the surface layers make an annual vertical migration into deep water in winter, and this migration by which they move from one current system to another is probably the means by which they keep within their normal geographical boundaries. The three species which in places make up the bulk of the Antarctic macroplankton, *Rhincalanus gigas, Eukrohnia hamata* and *Calanus acutus*, are mainly concentrated in the surface water in summer but descend into very deep water in winter. Since part of the Antarctic surface water moves in a northerly direction and there is a compensating southerly movement of the warm deep water, this vertical migration almost certainly results in the return of the species to the regions from which it originally came. The circulation is on a very large scale, the vertical range being from four to six hundred metres and the horizontal range being presumably some hundreds of miles.

Science News a Century Ago

South African Exhibits

In 1837, Smith Elder and Co. published "A Catalogue of the South African Museum now exhibiting in the Egyptian Hall, Piccadilly", the property of a society entitled "The Cape of Good Hope Association for Exploring Central Africa". The Association had been formed in Cape Town on June 5, 1833, and its object was the acquisition of knowledge relative to the geography, natural history and commercial resources of the interior, and of the social condition of its inhabitants. £537 were subscribed within a few days, and an expedition left Graff-Reynet in June 1834. The zoological and ethnographical exhibits were one of the sights of London, and were afterwards sold by auction by Messrs. J. C. and S. Stevens on June 6–8, 1838, in pursuance of a resolution passed by the Association, over which Sir John Herschel occasionally presided. The sale included a number of models of Kaffirs and specimens of the arts and manufactures of the Bechuanas, zoological specimens and a geological collection.

Geographical Society of Berlin

Under its foreign correspondence, the *Athenæum* of June 9, 1838, said: "The Geographical Society of Berlin held an extra meeting last month to welcome the former President, Prof. Charles Ritter, on his return from the scientific tour which he had made in Greece and the Levant. Prof. Lichtenstein, the actual President, expressed on the part of the Society great satisfaction in their renewed connexion with one who had done so much to advance the science of Geography. Prof. Ritter then gave a hasty sketch of the interesting observations which he had made in Greece and the Ionian Islands, in European and Asiatic Turkey and in Maldavia and Wallachia."

Karl Ritter, who was once described as "the greatest geographer of modern times", was born at Quedlinburg on August 7, 1778, and at nineteen years of age became a tutor in the family of Bethmann-Hollweg at Frankfort-on-Main. With his pupils he travelled through Switzerland, Savoy, France and Italy, and studied at Göttingen. In 1819 he was called to the gymnasium at Frankfort as professor of history, but the next year was made an extraordinary professor of geography in the University of Berlin. The great work, "Die Erdkunde im Verhältniss zur Natur und zur Geschichte des Menschen", which had established his reputation, had appeared in two volumes in 1817–18. He died on September 28, 1859, at the age of eighty years.

Zusseh Silkworms of India

At a meeting of the Asiatic Society on June 9, 1838, Dr. Geddes read a paper "On the Zusseh Silkworms of India". The moth of the Zusseh silkworm, he said, was the *Saturnia paphia*. The moth had been twice caught while depositing her eggs by Dr. Geddes —once in December 1826 and again in November 1830. The eggs deposited after that were, in each case, above 200; they were in small heaps, adhering together, and generally hatched in a little more than ten days. The interval between hatching and spinning was different in different larvæ from the same moth, being in some cases as long as 36 days and in others as much as 50. When fully grown, the larva is about 4 inches long, its head is light brown, its body green with rows of spots, orange, red and blue. Dr. Geddes fed them upon the leaves of the Ber tree (*Zizyphus jujubus*) but he had also seen them on the Ahseen (*Terminalia alata glabra*) on which the insect is fed in the Nagpore territories. The natives place them on the tree when hatched; and as soon as the leaves are devoured, they chop off the branches, and place them, insects and all, upon another tree. When ready to spin, the insect first forms a thick ligature of an inch in length which it fastens to a twig, and at the extremity it spins its cocoon, which sometimes reaches the size of a pigeon's egg.

The Actonian Prize

Early in 1838 the Royal Institution received a donation of one thousand pounds from Mrs. Hannah Acton. The gift, which was made out of respect and regard for the memory of her late husband, Mr. Samuel Acton, architect, was to form an endowment fund, and the trust established, which the Managers of the Royal Institution undertook, was to award a prize of one hundred guineas, once every seven years, to the person who should be "the Author of the best Essay illustrative of the Wisdom and Beneficence of the Almighty in such department of Science as the said Committee of Managers for the time being of the said Institution shall in their discretion select". In June 1838 the conditions governing the award of the Actonian Prize were made known. The first award was to be made in 1844, and the subject was to be chemistry. In due course the prize of 1844 was given to George Fownes for his essay on chemistry. Every seven years since, in accordance with Mrs. Acton's pious intention, the prize has been awarded. The list of the recipients contains many distinguished names, including those of Sir George Stokes, Sir William Huggins, Madame Curie, Sir Charles Sherrington, Dr. George Ellery Hale and Prof. A. V. Hill. The prize was last given in 1935 to W. T. Astbury, for his paper on "X-Ray Studies of the Structures of Hair, Wool and Related Fibres".

Ornithological Society

The *Gentleman's Magazine* for June 1838 contains the following account of the anniversary meeting of this Society held on May 18 with Mr. M. W. Colbourne in the chair. The Council in its report congratulated the members on the position which the Society had already obtained. The number of its members was stated to be 205, a number probably unprecedented in the first year of any other scientific society. Reference was then made to the great injury which the collection in St. James's Park at first sustained from the children and other frequenters of the Park; but the Council now had the pleasure of reporting that a marked improvement in this respect might be observed. Little more than a nucleus of the Museum and Library has as yet been formed, but the Council expressed a confident hope that with the valuable services of the curator, Mr. Blyth, a sufficiency of illustrations for the monthly lectures will be very shortly obtained. The accounts of the Society for the last year had been audited, and the balance in hand was £11 16s. The sums then owing by the Society were £36 17s. 9d. and the sums owing to the Society were £42.

University Events

Cambridge.—M. Black, of Trinity College, has been appointed University lecturer in geology, and W. W. Williams, of Fitzwilliam House, University lecturer in geography.

C. Culpin, of St. John's College, has been appointed University demonstrator in agricultural engineering.

Candidates for the Michael Foster studentship in physiology are requested to send their applications, with a statement of the course of research they propose to undertake, to Prof. E. D. Adrian, Physiological Laboratory, by July 7. The student receives the annual value of the fund (about £100), and may be re-elected for a second year.

Approval is sought for the plans prepared by Mr. C. Holden for the Austin Wing of the Cavendish Laboratory, and for the plans prepared by Mr. J. Murray Easton for an extension to the Psychological Laboratory.

The General Board recommends that a readership in medicine be established for one tenure only, and that the General Board be authorized to appoint Dr. McCance, at present assistant physician in charge of the Biochemical Department at King's College Hospital, London, to this post from August 1, 1938, with a pensionable stipend of £850.

The following have been approved for the degree of Sc.D.: Prof. J. F. Baker of Clare College, professor of civil engineering in the University of Bristol; C. Forster-Cooper of Trinity Hall, director of the British Museum (Natural History); and Dr. E. C. Stoner of Emmanuel College, reader in physics in the University of Leeds.

Glasgow.—The University has decided to confer the honorary degree of LL.D. on the following, among others, at the Commemoration Meeting on June 22: Prof. W. J. Jongmans, professor of palæobotany in the University of Groningen; Prof. Max Planck, professor of theoretical physics in the University of Berlin; Prof. M. J. Stewart, professor of pathology in the University of Leeds; Prof. C. T. R. Wilson, emeritus professor of natural philosophy in the University of Cambridge; and Prof. G. G. Henderson, emeritus professor of chemistry in the University of Glasgow.

Oxford.—Prof. J. H. Muirhead, emeritus professor of philosophy, University of Birmingham, has been appointed Herbert Spencer lecturer for 1939. His subject will be "The Man versus the State as a Present Issue".

R. H. S. Thompson, Trinity College, has been elected to a fellowship and praelectorship in medical science at University College.

In Congregation on May 24 it was announced that the Minister of Agriculture and Fisheries has appointed Lord Fleming, Sir Henry Bunbury, and Mr. Lawrence Holt to advise him on the representations of the University that part of the sum of £75,000, the cost of settling the action between the University and Sugar Beet and Crop Driers Ltd., should be borne by public funds.

Reading.—Mr. E. Capstick has been appointed to the newly instituted professorship of dairying as from September 30.

Societies and Academies

Paris

Academy of Sciences, April 4 (*C.R.*, 206, 1065–1151).

Pierre Lejay: Variations in the amount of moisture contained in the air in the neighbourhood of Shanghai.

Claude Chabauty and Charles Pisot: An algorithm for the simultaneous approximation of two real numbers.

Mendel Haimovici: The geometry of an integral.

Arnaud Denjoy: The singularities of analytical functions of functions defined by an element.

Armand Rauch: Integral functions of the class of divergence of positive order ρ.

Charles Blanc: A decomposition of the problem of the type of Riemann surfaces.

Henri Milloux: Holomorph functions and their derivatives in the circle unity.

Adrien Foch, André Fortier and Jean Fivet: The correction at the entrance of a cylindrical tube traversed by a gaseous current.

Victor Volkovisky: The transport of ions in a fluid moving with a supersonic velocity.

Damodar D. Kosambi: Homogeneous metrics in cosmogonic spaces.

Henri Grouiller: The determination of the curves of blackening in astronomical photographic photometry.

Pierre Lacroute: Variations in the spectrum of *P* Cygni.

Georges Durand: Orbit of the visual double star $O\Sigma$ 77 and the mass-luminosity relation.

Jean Louis Destouches: Remarks on the heavy electron.

Georges Fournier: Geometrical structure of space and electronic atmospheres.

Max Geloso and Pierre Deschamps: Researches on the mechanism of the electrolytic deposit of copper in the presence of iron salts.

Mme. H. Emmanuel-Zavizziano and H. Haïssinsky: Electrolysis of solutions of protactinium. Starting with titanium solutions containing actinium, a concentration of the latter can be obtained under suitable conditions of electrolysis.

Mlle. Lucienne Chaumeton: Magnetic study of the dehydration of crystallized copper hydroxide.

Pierre Rouard: Some optical properties of very thin sheets of platinum.

Mlle. Marie Louise Delwaulle, Félix François and Joseph Wiemann: Application of the Raman effect to the study of the complex compounds existing in solutions containing mercuric bromide and an alkaline bromide.

Bertrand Goldschmidt: The mixed precipitation of the sulphates of barium and strontium.

Jean Amiel: Paramagnetism of the organic cupritetrachlorides and cupritrichlorides.

Guy Emschwiller and Gaston Charlot: Solubility of calcium carbonate in solutions of ammonium salts. The increase in the solubility of calcium carbonate in the presence of ammonium salts is mainly due to phenomena of hydrolysis and only to a minor extent to the action of the salt.

André Borocco: Dissociation pressure of rubidium and cæsium hydrides and deuterides. The dissociation pressures of rubidium and cæsium deuterides are greater than those of the corresponding hydrides.

Guy Cogné : Zinc peroxide. The peroxide $ZnO_2.0{\cdot}5\ H_2O$, not hitherto isolated, has been prepared. From its reactions, it would appear to be a true peroxide, and not a compound of zinc oxide and hydrogen peroxide.

Raymond Delaby and Jean Hubert : Bromine index of the ethylenic nitriles.

Urbanski : Nitration of phenylnitromethane. Dinitrophenylnitromethane can be prepared by the intensive nitration of phenylnitromethane : it was shown to have the 1.3.5 constitution.

Marcel Tuot : Secondary reactions observed in the course of organo-magnesium condensation of the esters in the fatty series.

André Guillemonat : Oxidation of some substituted cyclohexenes by selenious anhydride.

Gilbert Mathieu : Recent deformations of the soil in the north-west of La Vendée and the reason for the existence of the Island of Yeu.

Gérard Waterlot : Structure and origin of the Poitevin marshland.

Jacques Flandrin : Main structural lines of the Djurdjura (Algeria).

František Link : Twilight phenomena visible during total eclipses of the sun.

René Bernard : Variations of intensity of the sodium *D* line present in the spectrum of the light of the sky at twilight. Discussion of the results obtained by Currie and Edwards in Canada, in the course of the International Polar Year 1932–33, with special reference to the observation of the *D* line of sodium in the atmosphere.

Gérard Gazet du Chatelier : Structure of the andrœceum of the Sterculiaceæ.

William Henri Schopfer and Samuel Blumer : Growth factors of species of the genus *Ustilago*.

Constantin Dawydoff : Two remarkable cœloplanids of Indo-Chinese waters.

Antoine Jullien and Daniel Vincent : The esters of choline in some organs of molluscs.

Paul Meunier and Yves Raoul : A vitamins and carotenoids. The kinetic study of the Carr-Price reaction. The rapid fading of colour in the Carr and Price reaction in the presence of acetic anhydride is characteristic of vitamin A_1 provided that the medium is free from unsaturated fatty acids.

Maurice Doladilhe : Anaphylactic properties of hæmolysin.

Erratum.—Maurice Henry Pirenne : The diffraction of X-rays by silicochloroform. The summary of this paper in Nature of April 16, p. 702, should read : "The valency angle is within two or three degrees of the angle of a regular tetrahedron. A plane structure of the $SiCl_3$ group, such as has been proposed by G. Urbain, is inadmissible."

Cracow

Polish Academy of Science and Letters, March 7.

T. Banachiewicz : A new aspect of quaternions.

W. Nowatke : Molecular dimensions of organic compounds and the constant of dialysis of their solutions. The author has shown that there is a direct relation ($\delta\sqrt{n}$ = constant) between the dialysis constant (δ) and the number of atoms in the molecule (n) and also between the dialysis constant and the radius (r) of the molecule ($\delta.r$ = constant).

J. Walas : The migrations of alpine plants along the water-courses of the massif of the Tatras.

Mme. M. Skalinska : Cytogenetic researches on the aneuploid *Aquilegia*.

J. Hans and Mlle. Z. Tabencka : The blood vessels in the skin of *Myxine glutinosa*.

H. Szarski : The subdermal corpus lymphaticum in the frogs *Rana esculenta*, *R. temporaria* and *R. terrestris*.

Z. Grodzinski and J. Marchlewski : The action of serum on the mobility of the spermatozoids of the cock.

L. Monné : The vital polychrome colorations of the different cells of gasteropods with the aid of pyronines.

Zb. Glowczynski : The proportion of vitamin A in the seed of canary grass, *Phalaris canariensis*.

Mlle. R. Skrochowska : Acquired habits in their relations with the repeated action of stimuli in *Vorticella*.

Rome

National Academy of the Lincei (*Atti*, 26, 193–251 ; 1937).

F. Enriques : Curves infinitely close together on an algebraic surface.

B. Levi : A property of the system of the *n*th partial derivatives of a function of more variables.

U. Cisotti : Mechanics of disperse continuous media.

G. Armellini : Fundamental problems of cosmogony and Newton's law (1).

C. Agostinelli : Integration of the differential equation

$$\frac{\delta^2 u}{dx^2}+\frac{\delta^2 u}{\delta y^2}+\frac{\delta^2 u}{\delta z^2}-\frac{1}{x}\,\frac{\delta u}{\delta x}=f,$$

and a problem analogous to that of Dirichlet for a hemispherical field (2).

M. Schönberg : A class of functional equations.

A. Colacevich : Spectroscopic and spectrophotometric observations of the comet Finsler (1937*f*).

A. Iandelli and E. Botti : Crystal structure of the compounds of the rare earths with metalloids of the fifth group (5). 1 : 1 compounds with bismuth.

E. Mariotti : Modification of van Slyke's method for the analysis of proteins.

L. Mascarelli and M. Pirona : Contribution to the knowledge of diphenyl and of its derivatives (19). Preparation of some new derivatives.

C. Perrier and A. Bellanca : The use of the potentiometer for the determination of time temperature curves in thermal analyses.

Atti, 26, 253–303 ; 1937.

G. Fubini : Asymptotic studies for some differential equations.

C. Mineo : Impossibility of a stratification of homotectic equilibrium for rotating fluid stars.

R. Woinarosky : Kinematics of a solid body in ordinary space of three dimensions.

G. L. Andrissi : Observations of the comet 1936 *a* (Peltier).

L. Gialanella : Meridian observations of Jupiter, Saturn, Uranus and of the moon in 1936.

G. Wataghin : Theory of elementary particles (1). A system of gravitational equations of the first order (2).

A. Cavinato : Observations concerning the note of S. Vardabasso "Contribution to the knowledge of the recent volcanism in Sardinia".

L. Mascarelli and B. Longo : Contribution to the knowledge of diphenyl and of its derivatives (20). A new example of the change from the diphenyl to the fluorene system : synthesis of 3-methylfluorene.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Tuesday, June 7

UNIVERSITY COLLEGE, LONDON, at 5.—Prof. B. P. Babkin: "The Physiology of the Digestive Glands" (succeeding lecture on June 9).*

ST. MARY'S HOSPITAL (INSTITUTE OF PATHOLOGY), LONDON, at 5.—Sir Henry Dale, F.R.S.: "Chemical Agents transmitting Nervous Excitation".

Thursday, June 9

RESEARCH DEFENCE SOCIETY (at the London School of Hygiene, Keppel Street, W.C.1), at 3.—Annual General Meeting.

Prof. C. H. Best: "Insulin and Diabetes: The Present Position" (Stephen Paget Memorial Lecture).

CHELSEA PHYSIC GARDEN, at 5.—Prof. E. J. Salisbury, F.R.S.: "Plants in Relation to the Human Environment" (Chadwick Public Lecture)*.

INSTITUTION OF PETROLEUM TECHNOLOGISTS, June 6–11. Conference on "Oil Shale and Cannel Coal" to be held at Glasgow.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned

LECTURER IN CHEMISTRY in the Battersea Polytechnic, London, S.W.11—The Principal (June 9)

LECTURER IN PHARMACEUTICS in the Leicester College of Technology and Commerce—The Registrar (June 13).

LECTURER IN PHYSICS AND MATHEMATICS in the Sir John Cass Technical Institute, Jewry Street, Aldgate, London, E C 3 (June 15).

ASSISTANT LECTURER IN MATHEMATICS AND ASSISTANT LECTURER IN ECONOMICS in University College, Swansea—The Registrar (June 17).

ASSISTANT LECTURER IN CHEMISTRY in the University of Sheffield—The Registrar (June 18)

EXAMINER in the Standards Department of the Board of Trade—The Assistant Secretary, Establishment Department, Board of Trade, Great George Street, S W.1 (June 18).

PROFESSOR OF PATHOLOGY and LECTURER IN PATHOLOGY in the University of Bristol—The Registrar (June 20).

ASSISTANT LECTURERS IN ORGANIC CHEMISTRY AND IN GEOLOGY in the University of Bristol—The Secretary (June 21)

PROFESSOR OF VETERINARY PHYSIOLOGY in the Royal Veterinary College, Camden Town, London, N.W 1—The Bursar (June 30).

ASSISTANT IN RESEARCH IN RADIOLOGY, ASSISTANT IN RESEARCH IN PSYCHIATRY and ASSISTANT IN RESEARCH IN PATHOLOGY in the University of Cambridge—Mr R. Williamson, Department of Pathology, Tennis Court Road, Cambridge (July 1)

TECHNICAL OFFICER in the Meteorological Office—The Secretary (S.2.a), Air Ministry, Adastral House, Kingsway, London, W C.2 (July 2).

WOMEN EXAMINERS and AN EXAMINER in the A.I D Test House, Kidbrooke, S E 3—(The Secretary, Air Ministry (I G.), Kingsway, London, W.C.2

TECHNICAL OFFICER at the East Malling Research Station, near Maidstone, Kent—The Secretary.

Archæological Studies in Ireland

IRELAND, for long not so much a neglected corner in the archæological field as the victim of a provincial outlook, is to come into her own as an element in the mosaic of European prehistory. She is at last to take her proper place in the pattern which a band of workers closely in touch with one another is rapidly piecing together, more especially in the north-western sector of Europe, of the early movements of cultures and peoples, from which has emerged the complex of modern Western civilization. To say this is not to ignore the achievement of Ireland's archæologists and historians in the past, many of them, like Sir William Wilde and George Coffey, of international repute. Granting these exceptions, in little more than a decade there has been a change in the spirit and orientation of Irish archæology which has diverted interest from exclusive preoccupation with Ireland as a unitary region, or as an appendage of Britain only, in such studies, and their bearing on the identification and history of the mythical races and peoples of early Ireland, to the wider horizon of the correlation of her development in civilization with that of Great Britain and the Continental mainland. The story of this change has been told recently by Dr. Adolf Mahr, keeper of antiquities and director of the National Museum of Ireland, in his presidential address for 1937 to the Prehistoric Society, of which a digest appears on another page of this issue of NATURE (see p. 1041).

To those familiar with the material, it may appear that even less than justice has been done to a remarkable achievement. In no more than one hundred and seventy-five pages—though assuredly the longest presidential address ever presented to a learned society—Dr. Mahr has summarized, discussed and placed in its true archæological perspective the great store of new information accruing in the last five years from the intensive archæological investigations which have been carried on in the Irish field. This information has been analysed and brought into relation not only with the cultural succession of Ireland's own prehistory, but also with the general archæological complex in northern Europe of the prehistoric period as a whole. In range it surveys from the alleged, but now disputed, Upper Palæolithic man of the Kilgreany cave in Co. Waterford, down to the Early Iron Age, and even beyond in an occasional glance over Dr. Mahr's self-imposed barrier into the Early Christian period, commonly known as Late Celtic. In passing from one period to another the survey pauses to discuss problems intrinsically fascinating, but even more compelling as vital for the understanding of Ireland's part in the general development of prehistoric culture as a whole.

Among these topics of discussion, the lithic civilization of the 'Riverford' people, newly recognized by Dr. Mahr himself in a culture which in Ireland appears to centre on the Bann River, is one of the first importance. Ultimately derivative from the Baltic Maglemose, and a manifestation of Prof. Gordon Childe's 'forest culture', it takes us back to the very springs of civilization in northern Europe, and it may be, as Dr. Mahr suggests, the clue to the identification of that ethnically obscure stratum in the peoples of Britain, the Picts—a suggestion which in its ramifications opens up interesting vistas of further research.

Scarcely less significant is the story of the Irish megalith, now told in the light of the recent crucial excavations of the 'horned' cairns of northern Ireland, and in relation to its bearing on the origin of the 'Iberic' element in the Irish population, the development of the Irish Bronze Age, and the survival of non-Aryan traits in Irish culture.

With the Late Bronze Age early in the last millennium before Christ there comes the break in culture and the incursion of a new people from Central Europe, the Celts. If they herald what is to most the very dawn of Ireland's greatness as the centre of culture she became in later centuries, they have also left a legacy of problems to puzzle modern generations—their origin, their distribution, and the relation of the two branches of the Celtic-speaking peoples, the *q* Celts and the *p* Celts, both to one another and in the composition of the British and Irish peoples—matters of perennial argument to which the latest research in Ireland contributes its quota. These problems are further complicated by the novel line of evidence of pollen analysis of the peat, which while it has afforded a new and assured datum line in late glacial and early post-glacial times in Ireland, threatens, as at present understood, to throw into confusion the chronology of the Late Bronze Age.

It is a temptation to follow further the fascinating array of problems, which have already engaged the attention of the archæologist, or lie before him in the prospect of further research, more especially in the field of recreating the religious and social concepts of the ancient civilization of Ireland, so far as this is possible by the interpretation of the evidence of archæology and of surviving custom and belief. On such matters, however, reference must be made to the text of Dr. Mahr's address. Enough has been said to indicate that archæological studies in Ireland are well advanced along a path which will lead not only to fuller knowledge and understanding of Irish civilization from the earliest phases through the cycle of its full development to eclipse, but by bringing it into touch with the European background will enable it to add its contribution to studies in a wider field.

For this great expansion in Irish archæological studies in the last decade no single circumstance, or set of circumstances, is entirely responsible. That the zeal of Harvard University for scientific research for its own sake inspired a like enthusiasm and emulation in Ireland is unquestionable ; but credit is mainly due to the public spirit and the vision of the Governments of Eiré and of Northern Ireland in directing measures for the relief of unemployment out of public funds into the channel of archæological excavation. But zeal without understanding is blind, and it was fortunate for Irish studies that there were among the men of science of Ireland those who were able to take advantage of their opportunities and devise a campaign of systematic research, from which the greatest and most generally valuable increase in the sum of knowledge might accrue. Even so, the gain might have been less, had it not been possible for Northern Ireland and Eiré to work in complete harmony and with the fullest measure of co-operation. Archæology in Ireland knows no political or geographical boundaries.

Newton

Isaac Newton, 1642-1727
By J. W. N. Sullivan. With a Memoir of the Author by Charles Singer. Pp. xx+275. (London : Macmillan and Co., Ltd., 1938.) 8*s.* 6*d.* net.

As the arts aspire to the nature of music, according to Pater, so the sciences aspire to the nature of mathematics. This at least would seem to have been the view of the late Mr. J. W. N. Sullivan when he devoted two of the principal efforts of his life, one to a work on Beethoven, the other to a work on Newton. From Prof. Charles Singer's memoir of the author, it appears that the latter was ten years in preparation. Even then the absence of chapter headings and occasional repetitions suggest that some final revision may have been intended. But a perfectly satisfactory manuscript existed at the time of the author's early death, and the book is in all essential respects a finished work.

This study deserves a respectful welcome, because it is a serious contribution in a field of literature which has been for the most part conspicuously neglected. While the lives of great artists, and of musicians in particular, have been studied over and over again with the most minute care, the lives of the great masters of science have generally been allowed to pass quickly into oblivion. The literature which has gathered round Wagner, for example, must already be immense. Even second-rate masters receive their tribute on a slightly lower scale. But in general the work of the great mathematician or man of science is quickly absorbed into the common stream of progress, while his life of individual effort is disregarded and forgotten. The biographical side of scientific history has been little cultivated, and a scientific parallel to literary criticism can scarcely be said to exist.

For all this there are obvious reasons. The man of science leads a regular and uneventful life. He is rarely temperamental and he is free from picturesque vices. The great artist is probably less emotional than is popularly supposed, but the emotional appeal of his work gives him a sensitive audience who are eager for details of his personal characteristics, either from mere curiosity or, more seriously, to gain some clue to the secret of his power. The appeal of pure science is to the intellect alone, and therefore the intimate contact of its greatest exponents with their contemporaries is commonly restricted in their lifetime and their personal relations afford little material for study afterwards. Thus their work must stand in popular estimation with none of that light which shines on the work of the artist.

The distinction is further remarkable because the "Principia" is a great work of art. So is the "Theoria Motus". So are many of the memoirs of the great mathematicians and physicists. They have an architectural quality which makes the whole far greater than the sum of its parts. The work of art in the accepted sense of the term is not susceptible of definite and certain analysis, and for that very reason it lures the critic to express his individual reaction to it. When it appears in the form of a scientific masterpiece, the work is ruthlessly disintegrated from the beginning. What are taken to be its most original and valuable elements—often erroneously—are seized upon and isolated, and the personality of the author comes to be seriously misrepresented or ignored altogether. The tendency is perhaps natural and inevitable, but it is none the less true that in this respect science is at a disadvantage when compared with the arts. Any attempt to redress the balance is welcome.

Materials for a life of Newton are scanty, and, such as they are, they are very apt to give a false and one-sided impression. Controversies take the form of correspondence, and as letters of this kind bulk largely among the documents which survive, it is hard not to give them an exaggerated importance. Mr. Sullivan has tried to hold the balance fairly between Newton on one side and Hooke, Flamsteed and Leibniz on the other. Whether he has altogether succeeded is doubtful. It might have been better to have reduced the treatment of these matters in scale and to have dealt more fully with less controversial aspects of Newton's life. The judicious reader will make some adjustment in this sense for himself.

It is not that these incidents, rather unpleasant as they may be and of a sort likely to occur in any career such as Newton's, are without interest. The greatest space is given to an account of the relations with Flamsteed. In these it is clear that Halley played an unfortunate part. The world owes too much to the association of Halley with Newton to be severely critical of Halley. But the peculiar circumstances of Flamsteed's appointment entitle him also to sympathy and understanding. No director of an observatory can be expected to welcome anything in the nature of dictation as to what his observing programme is to be, or as to when and in what form his observations shall be published. From interference of this kind Flamsteed was specifically exempted by the terms of his appointment. Halley's desire to see the Greenwich star observations published may have been natural enough, but any pressure in this direction was unjustified and as naturally resented.

Until the intervention of Halley, the relations between Newton and Flamsteed had been perfectly correct. Thereafter they steadily degenerated. Newton wanted selected places of the moon for a research on the lunar theory which he wished to keep secret, and which in fact came to no successful issue. He even resented a suggestion that the communication of Flamsteed's observations to him should be made known. Mr. Sullivan sees that Newton wished to treat Flamsteed as a mere tool, but he failed to see that this attitude was preposterous. He quotes from a letter of 1695: "By frequent trials and alterations of his contrivances, Kepler found out the true theory of the planetary motions. You must not be ashamed to own that you follow his example." This looks like genuine and acute criticism on the part of Flamsteed, who saw whither he was being led. Kepler's success with the problem of two bodies was largely due to a most skilful use of observations suitably selected from Tycho Brahe's material. Was a similar method applied to the moon likely to be equally effective in a case of the problem of three bodies? Flamsteed's scepticism seems to have been justified by the event. But Mr. Sullivan is consistently unfair to him. When it comes to the difference over the first election to the Plumian professorship, no charitable explanation is found. The choice of Roger Cotes may have been right, yet even now that seems far from certain. It provided Newton with an able editor for the second edition of the "Principia". But Cambridge may have lost the opportunity of establishing a school of observational astronomy at an early date. To attribute to Flamsteed unworthy motives in the matter is quite gratuitous.

In the dispute with Hooke, following the communication of the "Principia" to the Royal Society, Halley also played an unfortunate part. Hooke's remarks were made not publicly before the Society but on what must be considered a privileged occasion. On this point Halley misled Newton, and it may well be that his account of what was said was none too accurate. The dispute was composed and its personal aspect is not very important. What emerged from it is that the law of the inverse square had been common property within a certain scientific circle in England for some years. This is not remarkable, since it only needed a combination of Huygens's theory of uniform motion in a circle with Kepler's third law. It was thus left for Newton to prove that the same law of gravitation accounted also for Kepler's first and second law. The other discovery of fundamental importance related to the attraction of a sphere at an external and at an internal point.

Whatever may be said against Hooke—and Mr. Sullivan does not fail to say it—he came near enough to the discovery of the law of gravitation to prompt the question, why was no abler mathematician more successful in anticipating Newton ? The clue, it may be suggested, lies partly in the utter blindness to the nature of Kepler's work which prevailed on the Continent. In England it was different, thanks mainly to Horrocks. It is surely significant that the posthumous works of Horrocks were edited by Wallis and published in 1672 under the title "Astronomia Kepleriana defensa et promota". The tradition thus preserved in England enabled Newton to start with the inestimable advantage of having a definite problem to solve.

The third controversy in Newton's life was with Leibniz, though this was carried on not so much by the principals as by fervent partisans on the two sides. The rival claims to originality must seem trivial to-day. The progress of science had made the need for some appropriate form of calculus so obvious that the wonder is that there were no more than two claimants to the parentage. The difference between the two amounts to much more than a mere matter of notation. Newton was a geometer, Leibniz was an analyst ; though, as Poincaré has remarked, all early mathematicians are apt to look as if they belonged to the first category. This does not mean that Newton was a geometrician, though it is true his methods were largely geometrical. The distinction depends on the intuitive element in the mental processes. Now intuition was the secret of Newton's power and of his success. It gave him what he wanted, and for mathematics as such he cared little or not at all. But intuition has its weak side in being incommunicable. The main stream of mathematics flowing through Euler, Lagrange, Cauchy can be traced back to Leibniz ; it owes comparatively little to Newton. The challenge problems from the Continent are mentioned. It would have been much more impressive if the solutions had been given by some Newtonian, and not by Newton himself. In the little regard he attached to the source of his own greatness Newton is by no means unique, as Mr. Sullivan supposed. Pascal is a conspicuous example. Others who have abandoned a mathematical career for which they were eminently fitted can no doubt be quoted down to the present day. Sir Christopher Wren was reputed among his contemporaries at an early stage, and not without reason, as a mathematician scarcely inferior to Newton himself.

Like the "Principia", the "Opticks", first published in 1704, should be regarded as a work of art, to be treated as a whole. No better example of the danger of one-sided analysis and selection can be found than in this case. Had the book been published fifteen years earlier, it would have deserved all the praise it has received. As it is, it is hard to find excuses for Newton's blindness to the merits of the "Traité de la Lumière" of Huygens. But after reaching fifty years of age, Newton was a changed man, both in mental power and in temperament. It really seems as if the nervous breakdown which occurred about that time left lasting effects until the end of his life. The intense effort which produced the "Principia" had exacted a heavy toll. In this may be found an explanation of much that would otherwise appear mysterious in the life of Newton as a whole.

The experimental philosophy of Newton seems to have been native to him, but it can be traced back to Francis Bacon. Its principles were observed in practice even by a born Cartesian like Huygens, and they have only broadened with time. The laws of dynamics had become known well enough for terrestrial applications. Their formulation by Newton, coupled with the law of gravitation, then opened the field of celestial mechanics, in which the comparison of theory and observation afforded a means of verification to a far higher degree of approximation than experiment makes possible. Thus the true foundation of Newtonian mechanics is astronomical. It is still valid for calculations in its original field, from a range table to a planetary ephemeris. Mr. Sullivan follows the mode in disparaging the nineteenth century. But if it is impossible to indict a nation, it is even more difficult to indict a century. The chief criminal seems to be Clerk Maxwell, whose derivation of the field equations from the work of Faraday is an achievement of the same order as Newton's derivation of celestial mechanics from the work of

Kepler. But he was also chiefly responsible for the extension of Newtonian mechanics to a field not originally contemplated. Yet in doing so he was only following the first rule of experimental philosophy, which was realized in the seventeenth century and is still valid. In this philosophy, observations and experiments are the bricks, mathematical theory is the mortar; and the first rule, variously stated by Newton and by Huygens, is that the mortar must be reduced to a minimum.

In the seventeenth century the state of mathematics offered little temptation to depart from this salutary rule. To-day the position is different, and it seems altogether too early to anticipate what the final outcome will be. In the meantime, the issue commonly presented to the popular mind, whether Newtonian mechanics is right or wrong, seems altogether too crude. Newtonian mechanics, like Euclidian geometry with which it is inseparably bound, represents a necessary phase through which the human mind had inevitably to pass. If evolution is allowed in theology, it may fairly be admitted without reproach in science. From the scientific point of view reality is a chimæra of the philosophers. The word should have no place in the bright lexicon of science. Though Newton rated his scientific activities low and his other pursuits more highly, he never confused the issue between them. In the same way experimental philosophy, whatever difficulties may confront it, will work out its own salvation from within, not from without.

Theory of Integral Equations

Théorie générale des fonctionnelles: (Collection de monographies sur la théorie des fonctions.) Tome 1: Généralités sur les fonctionnelles; Théorie des équations intégrales. Par Prof. Vito Volterra and Prof. Joseph Pérès. Pp. xii + 359. (Paris: Gauthier-Villars, 1936.) 100 francs.

IN the modern mathematical development of operational methods, the theory of integral equations has yielded a calculus of so broad a generality that it has very considerably extended the field of analysis. The foundations of the theory were laid almost simultaneously by E. I. Fredholm of Stockholm and Vito Volterra of Rome, whose brilliant papers opened to the mathematical world one of its most fertile regions. The first treatises on the subject were two monographs written by Prof. Volterra and published in Paris in 1913. They were entitled, "Leçons sur les fonctions de lignes" and "Leçons sur les équations intégrales et les équations intégro-différentielles", and were based upon courses of lectures given by the author at the Sorbonne and at Rome respectively. In 1936, a new edition of the latter book became necessary and, in view of the rapid progress made in the theory since 1913, the author in collaboration with Prof. Pérès, of Paris, decided to rewrite the work under the new title, "Théorie générale des fonctionnelles", of which the book under review is the first of three volumes.

It may be remarked here that the modern calculus of functionals began in 1887 when Volterra published a series of papers in the *Rendiconti della R. Accademia dei Lincei* in which the term *functions of lines* was used. The designation 'functional' (*fonctionnelle*) was first employed by J. Hadamard in a paper "Sur les opérations fonctionnelles" (*Comptes rendus*, 136, 351–354; 1903); and in the "Theory of Functionals", an English translation of a course of lectures given at the University of Madrid in 1926 and afterwards published in Spanish, Prof. Volterra writes: "The name *function of a line* was initially taken to mean what, in general, is now called a *functional*".

The text of the present volume is based upon parts of the earlier work, already mentioned, which it replaces, and also upon the Madrid lectures. It is divided into two parts. The first, consisting of five clearly written chapters, introduces the notion of a functional and then explains the general properties of functionals, such as continuity, series of homogeneous functionals, differentiation, integration, etc. The subject-matter is drawn freely from that of the first chapter in the "Theory of Functionals", referred to above, with considerable extensions from the researches of Fréchet, Levy, Pérès and Riesz.

The second part, occupying the remaining six chapters, is devoted to the modern theory of integral equations, which is treated quite rigorously. The first section (Chapters vi and vii) is concerned with the author's well-known equations of the first and second kinds. The singular case of the former receives full treatment both by the author's original method and also by a new one due to Prof. Pérès. Then follows a lucid discussion of Fredholm's equation, the two cases depending upon the non-vanishing and the vanishing of the fundamental determinant D(λ) being considered. Here is included also a new method by M. Pérès of obtaining the functions of Schmidt.

Finally, a section has been devoted to a treatment of non-linear equations in which much of the recent work of Schmidt, Leray and the author has been incorporated. An extensive bibliography and index have been provided at the end.

Students of all ages will be grateful to the authors for producing such a volume in which the results of so much modern research are to be found. The work is, undoubtedly, a very valuable and important contribution to the theory of integral equations. F. G. W. B.

Agricultural Policy for Peace and War

Famine in England
By Viscount Lymington. Pp. 271. (London: H. F. and G. Witherby, Ltd., 1938.) 7*s*. 6*d*. net.

LIFE in Britain has carried a commercial and industrial bias for so long that any thought of an exodus to the land seems anachronic, much as a movement in that direction would benefit national health and security. Lord Lymington is among those who would deprive industry, trade and usury of their present domination; and, even at the cost of losing foreign investments and overseas trade, he would seek to establish a new Eden where, *inter alia*, humus would be enshrined as the goddess of fertility, and agricultural chemicals consigned to the bottomless pit! We must, he says, stop exploiting the land for temporary economic gain, and return to 'good farming' by restoring and maintaining soil fertility. Capital taken from the land as tithe and death duties must be returned to it, so that we may be able to renew dead stock, increase live stock, settle far more people on the land, and produce far more home-grown food than we now do. We must, too, regenerate the land in order to regenerate our people.

The first step should be to make Britain immune from starvation in time of war, and its sequelæ, or panic, disease and civil war. Our normal reserves of food are very small, and our means of increasing production and of importing supplies in wartime are much inferior to what they were in 1914; and the potential menace from air-attack on land and sea is many times greater. For these and other reasons the author advocates the policy of dispersed inland storage of essential foodstuffs (which the Government has now adopted, except that wheat will be stored in ports on the west coast). The demand for a whole year's reserve supply of wheat seems, however, to be excessive, for in time of emergency we could at once increase the milling percentage from 70 to 92–94, with much benefit to the health of the people, and admix the wheat with barley and potato; we could grow more wheat for grain instead of for straw, and cease to feed it to poultry; we could start now to plough up our deteriorated pastures and eventually sow down some of them to wheat; and by the judicious use of fertilizers we could increase crop yields by 1½–2 cwt. per acre.

The author's proposal to build up soil fertility on the basis of a large livestock population during peace, and gradually to kill off the animals, except the dairy cattle, during war, appears thoroughly sound; but his long-term policy of increasing cattle numbers by 60 per cent, and doubling present numbers of sheep, pigs and poultry, though physically possible would, as he realizes, get us into difficulties with the Dominions and certain foreign countries. He foresees declining food supplies from most of the food-exporting countries, and for this reason also he favours a policy of national sufficiency in foodstuffs.

Lord Lymington has a very doleful tale to tell of Britain's neglect of agriculture and its far-reaching consequences, but unfortunately he is apt to overstate, and here and there to misstate. The assertion that "without hesitation, one can say that from Land's End to John o' Groats the soil in general is deteriorating" should have been backed by evidence. It is no doubt true of our run-out pastures, but there is no supporting quantitative evidence for our arable soils, the official crop returns from which show no material change; and in the case of wheat, a recent study by the Food Research Institute of Stanford University reveals that the trend of yields in the British Isles from 1885 to 1935 has been one of slow increase.

Further examples of unwarranted generalization are the statements that the use of poison sprays to kill charlock causes "a dead, unhealthy soil, in which no crop can flourish naturally", and that "most of the apples we now eat are sprayed with arsenic". Chlorination of water-supplies also comes under the author's ban for some unspecified reason; and his oft-repeated denigration of inorganic fertilizers, based apparently on their occasional misuse, shows that he has listened uncritically to a vocal few who, in their justifiable enthusiasm for humus-producing manures, exceed the bounds of experience by postulating an antagonism between the two kinds, ignoring the fact that in general they are complementary.

The book is well written except for misuse of 'will' and 'shall', 'would' and 'should', recalling the time-honoured S O S : "I will be drowned, no one shall save me". It should appeal to all the regenerate scientific men who now take an interest in social relations, but being somewhat too 'extreme' and dogmatic, it is not an entirely safe book to place in the hands of the million, for whom it was obviously written.

E. H. T.

British Birds

The Handbook of British Birds
By H. F. Witherby, Rev. F. C. R. Jourdain, Norman F. Ticehurst and Bernard W. Tucker. Vol. 1 (Crows to Flycatchers). Pp. xl + 326 + 32 plates. (London: H. F. and G. Witherby, Ltd., 1938.) 25*s.* net; set of 5 vols., 21*s.* net each.

THE eagerly awaited first volume—there are to be five in all—of the "Handbook of British Birds" has now made its appearance. It may be said at once that the work is fully up to, and indeed exceeds, the high expectations formed. The editors, all of them distinguished ornithologists, have laboured long, unostentatiously and with sustained enthusiasm to make the book a success, and it is safe to say that neither in Britain nor indeed in Europe is there in existence so complete and accurate a work on birds.

A feature of this volume—as it will be of the four succeeding volumes—is the coloured plates which portray the bird, both male and female, in summer, winter, and immature plumage. These plates are finely reproduced, and the colouring of the birds is clear and faithful.

In their preface, the authors tell us something of the history of the work, which has been with them a labour of love. Their aim was to produce something that would be of practical value not only to the expert, but also to the beginner and to the student interested in birds yet knowing little of them, and they have admirably succeeded in their task. The many readers of the "Practical Handbook", which was the ornithologists' Bible and which went out of print in 1934, will be interested to learn that the present work is much more than a new and enlarged edition of that 'Handbook". New and valuable features have been introduced. One of these is a chart of song periods, prepared by Mr. H. G. Alexander—the fruits of thirty years close observation; another is the descriptions of display and posturing, written by Mr. Jourdain and Mr. Tucker; a third is a series of maps showing the breeding sites of certain local species in Britain, and the migrations of certain species, discovered by the *British Birds*' ringing scheme. The inquirer can indeed turn up any British bird at random, and read, placed before him clearly and concisely, all that is known about it.

No book of this kind could have been produced without extensive researches into the subject, and it is pleasant to see that the ornithologists—a considerable company—who have supplied information are individually thanked in the preface.

When this volume is compared with the older standard works on British birds, it is seen at once how greatly the number of species has increased. To take an example; in the old days an author described the jay, and thought that there was one, and only one, species of jay in the British Isles. The experts of the present day have discovered that no fewer than three species of jay may be found in the British Isles—the British jay, the Irish jay and the Continental jay, all with small, but quite distinct, differences of appearance. Let us take another bird, the crested tit; old authors were not aware that three species of this bird had been found in Britain—the Scottish crested tit, the Northern crested tit and the Central European crested tit. Other examples are the British blue tit and the Continental blue tit; the British long-tailed tit and the Northern long-tailed tit; the British tree creeper and the Northern tree creeper, and so on.

Whether this differentiation of species may be carried too far is a controversial subject—the late Abel Chapman was a strong opponent of it—but there is value in the descriptions of all the recognized species, and it should now be possible for the student to discover from a bird in the hand whether it is a native of Britain or an immigrant of an allied Continental race.

Another thought must occur to the reader of this work—the remarkable spread of certain species into areas where they were hitherto unknown.

I hope the education authorities of Britain will take notice of this work, for I can imagine nothing more likely to encourage nature study in the younger generation. In our great public schools also, the completed five volumes might be given as a most valuable prize.

Since we have now the finest bird book in Europe, let us see that we become up to date with our Wild Bird Protection Acts, and let us arouse public opinion to save those species of birds which seem—unless some special measure is taken for their preservation—doomed to extinction.

SETON GORDON.

Höhere Mathematik für den Praktiker

An Stelle einer funfte Auflage des "Lehrbuchs der Differential- und Integralrechnung" von H. A. Lorentz. Neu bearbeitet von Prof. Dr. G. Joos und Prof. Dr. Th. Kaluza. Pp. xii+364. (Leipzig: Johann Ambrosius Barth, 1938.) 23 gold marks.

"WHY do men write big books?" asked Bernard Shaw. "Because they haven't time to write small ones!" The authors of this small book must have expended a great deal of time and energy in selecting essentials and presenting the mathematical methods and results which are most needed by engineers and physicists. The range covered is amazingly wide.

Starting with permutations, combinations, and the binomial theorem, we go on to probability, determinants, complex numbers, progressions, exponentials and logarithms, trigonometry, vectors and analytical geometry of two and three dimensions. These subjects receive only a few pages apiece, but the talent of the authors for compression makes the treatment really valuable. Much more space is given to the differential and integral calculus, which go as far as maxima and minima of functions of several variables and the transformation of double and triple integrals. There is a short section on Fourier's series and integral, including the use of the harmonic analyser. Differential equations are solved numerically and graphically, as well as by the usual elementary methods, and there is a brief account of partial differential equations. This is followed by a section on the calculus of variations. There are seven pages on functions of a complex variable, and in this the authors succeed in giving an intelligible account of conformal representation and Cauchy's theorem, with an application to the evaluation of a definite integral by means of contour integration. The book concludes with answers to examples and an index.

Naturally there are many portions of this book which the specialist will condemn as inadequate, but the object of the authors is to give a wide general view, and their work will be welcomed as a gallant counter-attack against the forces of narrow specialization. H. T. H. PIAGGIO.

Histoire générale du tissu

Document No. 2: Tissus anciens. Partie 1: Le Kaunakès; étude critique d'après les textes, les monuments, figurés et les survivances supposées du tissu. Par Émile Cherblanc. Pp. 66+16 plates. (Paris: Les Éditions d'Art et d'Histoire, 1937.) 30 francs.

IN this second study in the series dealing with the history of weaving, M. Émile Cherblanc reviews the evidence from all sources, including that now made available by recent archæological discovery in Irak, bearing on the nature of the garment, reputedly of Chaldean origin and known to classical writers, notably Aristophanes, Menander and Pollux, as the kaunakes (καυνάκης). M. Heuzey in 1886 in a communication to the Académie des Inscriptions et Belles Lettres concluded, on the evidence of two monuments, as well as the literary sources, that the kaunakes was an oblong mantle of wool with a long pile, which was worn draped simply about the body.

In the light of the evidence now brought under review, M. Cherblanc concludes that the examples from the monuments upon which M. Heuzey relied represent two distinct classes of material, one a sheepskin of which the fleece was retained, and the second composed of skins joined and sewn together. In the third and second millennium B.C. and the pre-Hellenic period, the term did not refer to a fabric. In the time of Aristophanes it was used of a garment of Persian origin made of a thick and heavy material, in which a large quantity of wool was used. This was worn on the shoulders and probably was semicircular in form like the κατα φλοκατας of the modern Greek shepherd, and possibly with the same goat-skin texture. The author maintains that the allusions to the kaunakes in all classical authors, with the exception of Martial, can be shown to agree with the meaning of a garment of sheepskin which retains the fleece. An examination of the Coptic 'knot' pile fabric, which through the '*point sarrasinois*' had an important influence on the Eastern and European carpet fabrics, shows it to be entirely Egyptian in origin and unrelated to the kaunakes.

M. Cherblanc's ably reasoned study is very fully illustrated by material from the monuments and diagrammatic sketches of the technical points and processes involved in the argument.

Contributions to the Microscopic Anatomy of the Pancreas

By Paul Langerhans (Berlin, 1869). Reprint of the German original with an English translation and an introductory essay by Dr. H. Morrison. Pp. 39. (Baltimore, Md.: Johns Hopkins Press; London: Oxford University Press, 1937.) 4*s*. 6*d*. net.

THIS little work, now reprinted from the *Bulletin of the Institute of the History of Medicine* (March 1937), contains one of the classics of medicine, which was presented by the medical student Paul Langerhans in 1869 at the age of twenty-one years as his inaugural thesis for the degree of doctor of medicine at the Berlin Faculty. The thesis constitutes not only the first detailed account of the microscopical anatomy of the pancreas, a subject which had hitherto been neglected by anatomists and physiologists but also the first description of peculiar groups of cells in this organ, the nature of which Langerhans was unable to explain. In 1893, however, they received the name of "islands of Langerhans" from the French histologist Laguesse, who first suggested that they were the seat of the internal secretion of the pancreas; but it was not until 1921, or more than fifty years after the appearance of Langerhans' thesis, that insulin, the specific cure of diabetes, was isolated from these cells by Banting and Best of Toronto.

In addition to the German original and English translation of the thesis, the work contains a short account of the life and work of Langerhans, who died at Madeira at the early age of forty-one years; there is also a list of his publications and portraits at different ages.

River Pollution and Waste Waters from the Milk Industry

By Dr. A. Parker

DURING recent years, the problems of treatment and disposal of the waste waters from the milk industry have increased in importance with the development of the industry in England and the establishment of depots and factories each receiving milk from many farms. Serious pollution of rivers and streams and difficulties at sewage disposal works in many parts of the country have been caused by discharges of waste waters from milk collecting and distributing depots and from factories making cheese, butter, condensed milk and other milk products. About four years ago, an investigation of the various problems was begun by the Water Pollution Research Board of the Department of Scientific and Industrial Research. Though the investigation has not yet been completed, it has already provided results of considerable practical value. It is the purpose of this article to give a brief description of those results.

In attempting to solve any problem of treatment and disposal of trade waste waters, the first step should always be to consider the practicability, taking costs into account, of so modifying the manufacturing processes that the wastes need not be produced or that the polluting matter carried away in the wastes is greatly reduced in quantity. Methods of purification of waste waters should only be considered after all practicable modifications in the factory processes have been adopted to reduce the polluting character of the wastes or to re-use the waste waters in the factory. Frequently the polluting character of the waste waters can be reduced by reducing losses of valuable material in the factory, or by recovering products or by-products of value. This is the first line of attack which has been followed in the Water Pollution Research Board's investigation of the problem of pollution by the waste waters from the milk industry.

The investigation has shown that even at milk collecting and distributing depots, where the milk is received only for cooling, pasteurizing and distribution, the waste waters from washing delivery churns, coolers, pasteurizers, tank wagons, other equipment and the floors usually carry away 0·5–1·0 per cent of the milk received. This means that the waste washing waters from a collecting and distributing depot handling 10,000 gallons of milk a day usually contain 50–100 gallons of whole milk. The volume of waste washing water in relation to the volume of milk handled varies considerably at different depots. If the volume of washing water is about the same as the volume of milk handled, 10,000 gallons of milk a day received in a collecting and distributing depot give rise to 10,000 gallons of waste water containing 0·5–1·0 per cent of milk. As measured by the test for dissolved oxygen taken up from aerated water in five days, water containing 1 per cent of whole milk has a biochemical oxygen demand of about 120 parts per 100,000 parts. Average domestic sewage has a biochemical oxygen demand of 40–50 parts per 100,000, and the volume of domestic sewage is usually about 25 gallons a day per head of the population. A volume of 10,000 gallons a day of waste water containing 1 per cent of milk is thus equivalent in its de-oxygenating or polluting effect on a stream to the domestic sewage from a population of about 1,200.

From factories making cheese, butter, condensed milk and other products, in addition to washings from delivery churns, there are waste waters from washing cheese vats, butter churns, evaporators and other equipment. Even when care is exercised to reduce the losses of milk, of the main products and of the by-products whey, buttermilk and skim milk, the waste washing waters from cheese and butter factories contain organic matter equivalent to at least 2 per cent of the milk handled. At many factories the waste washing waters from the manufacture of cheese and butter contain organic matter equivalent to 3–4 per cent of the milk handled, and as much as 6–8 per cent has been found at some factories.

In the past, some factories have considered whey and buttermilk as waste materials and have discharged them into the nearest stream, with disastrous polluting effects. Whey has a biochemical oxygen demand of 4,000–5,000 parts per 100,000, so that it is approximately a hundred times as strong in polluting character as an equal volume of crude domestic sewage. In other words, if the whole of the whey from a cheese factory handling 10,000 gallons of milk a day were discharged into a stream, its polluting effect would be about the same as that of the crude domestic sewage from a town with a population of 40,000–50,000 people. Whey and buttermilk should be treated as valuable by-products, not as waste materials. They have high food values and can be utilized as food or in the preparation of foods. There is a market for dried whey and buttermilk, and there is no doubt that this market can be further developed.

From the Water Pollution Research Board's investigation, it has definitely been concluded that the quantities of polluting matter carried away in the waste waters from the various branches of the milk industry can be considerably reduced by simple and inexpensive modifications in the operations within the factories, and by more careful control of the processes of draining and washing. At most depots and factories, the delivery churns are rapidly emptied and insufficient time is allowed adequately to drain the churns before they are transferred to the washers. By installing a simple drainage rack with a milk collecting-channel beneath and allowing the churns to drain on the rack for one or two minutes, the quantity of milk carried away in the water used for washing the churns can be reduced from more than 0·5 per cent to less than 0·25 per cent of the milk handled. This saving has definitely been effected at a large factory. It represents a saving of about 10,000 gallons of milk or £750 per annum, with milk at 1*s*. 6*d*. per gallon, for a collecting and distributing depot receiving an average quantity of 10,000–12,000 gallons of milk a day. If adequate drainage trays were installed at all the depots and factories in Great Britain, the total saving of milk would be roughly 3 million gallons per annum, or £150,000 per annum with milk at an average wholesale price for all purposes of 1*s*. per gallon.

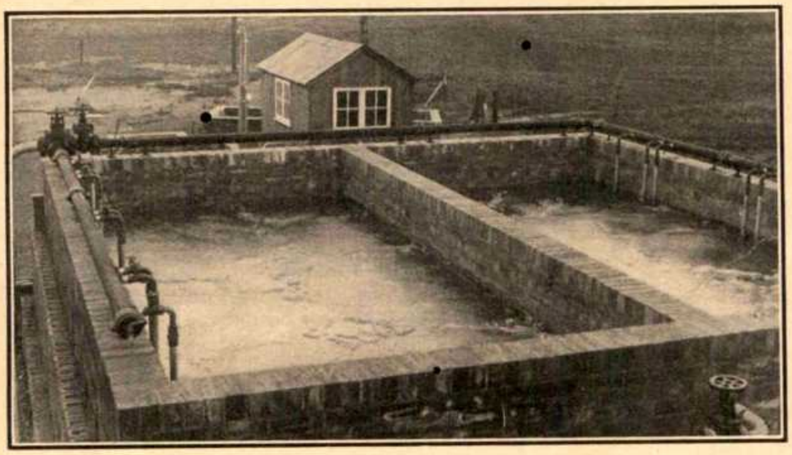

Fig. 1.

AERATION TANKS OF EXPERIMENTAL PLANT FOR THE TREATMENT OF MILK EFFLUENTS BY THE ACTIVATED SLUDGE PROCESS.

Reproduced by permission of the Controller, H.M. Stationery Office; Crown copyright reserved.

Substantial improvements can usually be made also in the methods of draining and washing cheese vats, butter churns and other equipment to bring about considerable reductions in the quantities of whey, buttermilk and other products in the waste waters. Cheese vats and butter churns, after the removal of whey and buttermilk, should first be washed with small quantities of water which should be added to the whey and buttermilk for use as food or for the preparation of foods. Subsequent washings with larger quantities of water would then contain much less polluting matter. Modifications of this kind not only cause direct savings in the factory but also reduce the size and the cost of construction and operation of the plant required for the treatment of the waste waters.

The next step in the investigation was to study possible methods of purifying the waste waters unavoidably produced. Plants in France and Belgium which were satisfactorily treating waste waters from condensed milk factories were visited. These plants utilize the activated sludge process according to the method devised by H. Kessener of Holland. Experiments made in the laboratories of the Rothamsted Experimental Station for the Water Pollution Research Board indicated that it would be practicable to purify the waste waters either by the activated sludge process or by the process of biological oxidation in percolating filters operated under certain conditions. In the experiments with percolating filters it was found that in single filtration, by the method normally employed in the treatment of sewage at sewage disposal works, solid matter was deposited in the top layers of the filter, which in consequence became choked and inoperative. It was found, however, that this difficulty could be overcome by adopting a method of biological filtration suggested by H. C. Whitehead and the late F. R. O'Shaughnessy of the Birmingham, Tame and Rea District Drainage Board. By this method, the waste waters, after sedimentation to remove suspended solids, are passed through two biological filters in series, and the order of the two filters in series is changed at intervals of two or three weeks. Under suitable conditions, the partially treated effluent from one filter brings about the removal of the solid matter previously deposited in the top layers of the other filter, when this filter occupied the primary position.

With the financial co-operation of the industry, the investigation was extended to include experiments on a large scale at a cheese factory in Shropshire, where United Dairies Ltd. provided the necessary facilities. Through the Milk Marketing Board and the Scottish Milk Marketing Board, the industry has contributed nearly £11,000 towards the cost. Two large experimental plants were erected at the factory in Shropshire during the summer of 1935. In one plant, the waste waters, after sedimentation, are treated by the activated sludge process (Fig. 1) operated in a manner similar to that adopted for the treatment of sewage at sewage disposal works. In the other plant (Fig. 2), the settled waste waters are submitted to biological oxidation in two percolating filters in series, and the order of the filters is reversed at intervals of ten days to three weeks. Each filter contains hard metallurgical coke, graded 0·75–1·5 in. Both plants have been in continuous operation since their erection in July 1935, in the treatment of milk washings and mixtures of milk washings and whey washings. For the activated sludge process, the settled crude waste is diluted, if necessary, to give a mixture with a biochemical oxygen demand of not more than 50 parts per 100,000 parts. From this mixture, with a period of aeration of twenty-four hours, a final effluent with a biochemical oxygen demand of about 1 part per 100,000 is obtained. For the biological filtration plant, the settled wastes are diluted to give a mixture with a biochemical oxygen demand of not more than 30 parts per 100,000 parts. From this mixture a final effluent with a biochemical oxygen demand of less than 1 part per 100,000 parts is obtained, even with the high rate of treatment of 240 gallons a day per cubic yard of filtering medium in the two filters together, that is, 480 gallons a day per cubic yard in each filter. This is a rate of treatment much greater than that usually adopted in the treatment of domestic sewage at sewage disposal works in Great Britain. Tests over long periods have shown that trout are able to live in the undiluted final effluents from the experimental plants.

Of the two methods investigated for the treatment of milk effluents, the process of biological filtration with two filters in series and periodic change in the order of the filters appears to be the more suitable for operation under factory conditions. To allow a margin of safety, the diluted settled crude liquid should be supplied to the filters at a rate not greater than 160 gallons a day per cubic yard of filtering medium in the two filters together. During the past two years, several plants designed on the basis of the experimental filtration plant have been erected at depots and factories in different parts of the country, and other similar plants are in course of construction.

New Aspects and Problems in Irish Archæology*

THE acquisitions of new archæological material by the National Museum of Ireland now represent a yearly increase forty times larger than that of ten years ago. The old-established collection of Irish antiquities contains an unusually high percentage of unlocalized or ill-localized specimens; but the National Museum is now building up a second collection, each object accurately located, which at least in numerical strength compares with the old one and will serve as a basis for distributional studies.

During the past five years, large-scale systematic excavations have been undertaken, which have contributed to the clarification of at least some of the most hotly contested problems in the archæology of Ireland. No comprehensive survey of Irish archæology, however, can as yet be made, though this may be possible in ten years time. Five years' excavation has merely touched the fringe of the problems before us.

---

* Substance of the presidential address for 1937 by Dr. Adolf Mahr to the Prehistoric Society. *Proc. Prehist. Soc.*, 3, 2, pp. 262–436 + 7 plates (1937).

Recent progress in the conception of Irish archæology is in no small measure due to the fact that protective legislation of national monuments is now bearing fruit. The respective administrative and advisory organizations of the Free State and of Northern Ireland co-operate freely; and the archæological activities of the Royal Irish Academy and of the Royal Society of Antiquaries of Ireland are fully all-Irish in character.

No systematic excavation worthy of the name had been undertaken for many years. The opportunity to make a fresh start came with the proposal of Dr. B. H. O'Neill Hencken for the Harvard University Archæological Expedition to Ireland, which as part of a larger scheme of anthropological investigation in Ireland, excavated for five years in succession, from 1932 until 1936. Sites of a size never attempted before were then excavated, not with the object of collecting antiquities, but purely with the aim of obtaining scientific evidence. It taught Ireland scientific methods of excavation, and trained Irish workers in technique. In 1934 the Free State's scheme for the relief of unemployment opened the way to systematic excavation on an unprecedented scale, and a similar measure was adopted in Northern Ireland in 1935. In the Free State, no fewer than twenty-six excavations have been carried out, many extending over more than one season, and nearly all devoted to sites of outstanding importance. Irish, English, American and Danish archæologists have participated in the work. In addition, 'licensed' excavations have been carried out by the learned societies and private individuals.

In the most important department of the correlation of all evidence available, little work has been done. The Belfast Field Naturalists' Club in 1930 set about launching a cartographical survey of monuments, archæological sites and antiquities generally in Northern Ireland, of which the preparation was entrusted to Miss M. Gaffikin. In 1935 two distribution maps were published, one of megalithic monuments, the other of raths, cashels and crannogs. Some six hundred megalithic monuments have been listed, and some two thousand of the later monuments; but the authors disclaim completeness.

Physical anthropology has been neglected for so long in Ireland that Prof. C. P. Martin's book "Prehistoric Man in Ireland" is an almost unhoped-for achievement. His work is being continued by Prof. I. K. Jamieson, of Trinity College, Dublin.

Investigation of the problems of the peat, the most important source of Irish archæological material, was begun by Prof. G. Erdtmann in his studies of pollen analysis (1928), and is being continued by Prof. K. Jessen, of Copenhagen, and the Committee for Quaternary Research in Ireland. Important, if at present tentative, conclusions, based on evidence from sixty sites, as to late glacial and early post-glacial events and chronology have already emerged, while conclusions of a like tentative character as to climatic change at the beginning of the Late Bronze Age, when correlated with similar phenomena in north-western Europe, by placing this phase of the cultural succession in Ireland at a period some centuries later than that accepted by archæologists, opens up an important field for further investigation.

It was from work such as these bog investigations, from the large-scale excavations, and from the ancillary activity in the National Museum offices that the modern conception of Irish archæology arose and recent progress is due. Four major results stand out, of which three are due to excavation work. These are: first, as a result of excavations in Northern Ireland, the history of an almost forgotten but important megalithic monument, the horned cairn, with its derivatives, is now clear; secondly, it is known that the souterrain, as a type, can be as old as the Middle Bronze Age; thirdly, at least one crannog, that of Knocknlappa, Co. Clare, belongs to the Late Bronze Age, in other words, antedates the La Tène period: and fourthly, partly by excavation work, but principally by analysis and comparison of museum material, a hitherto unobserved cultural facies, the Riverford lithic civilization, has been recognized.

Dr. Mahr proceeded to discuss the evidence for the existence of the stone culture to which he has given the name of the 'Riverford civilization' and its relation to the stone cultures of Britain and northern Europe, and then turned to a critical and constructive examination of the fresh evidence bearing, more especially in relation to the European background, on the palæolithic and mesolithic periods, the neolithic period, megaliths, their derivation and distribution, megalithic art, the Bronze Age, and the early Iron Age. In summing up an analysis of the 'Keltic' problem, in which he follows a line of argument reverting more or less to the position on the *p* and *q* problem of Sir John Rhys, Dr. Mahr outlines the general conclusions of the archæological evidence as follows:

We have been able to trace the following immigrations or invasions into Ireland. (1) A mesolithic stratum. Probable source: the western continent. Route: south Britain. (2) Another lithic stratum, the Riverford people, or the Picts. Ultimate source: Maglemose culture somewhere around Denmark. Route: Doggerbank — Scotland — Hebrides. (3) The Megalithic invasion, heralding the Bronze Age. About 2100 B.C. Source: Iberia. Route: Brittany—Cornwall—Irish Sea. (4) The Late Bronze Age invasion. About 900 B.C. Source: Middle (and Lower ?) Rhine and eastern, plus northern France. Route: Lowland Britain—Cumberland—Wigtownshire. (5) The La Tène wave. About 200 or 150 B.C. British Kelts coming from Wigtownshire occupied only a limited district of north-eastern Ireland.

Of these, (3) was certainly a non-Aryan movement. Much of the non-Indo-Germanic traits of ancient Ireland must be due to it. (4), however, came from a region in which the Kelts were deeply rooted. It was probably the Keltic cradle; while (5) was an aristocratic conquest by bands, who came apparently without their womenfolk.

In reference to the aims of future research, one thing stands out clearly. The rigid canons of European prehistory are applicable to Ireland only with considerable qualification. They hold good so far as the general sequence goes, but some periods culturally so far outweigh others as almost to eclipse them. The only cultural strata in Ireland which really matter are (1) the basically 'lithic' Riverford complex; (2) the megaliths, and the earlier part of the bronze age they signify; (3) the Late Bronze Age (and the Kelticization of the country it brought about); and (4) the Early Christian period. There are periods in which Ireland has an importance for all Europe quite out of proportion to its size, and others in which she is simply an appanage of Britain.

The international importance of Irish archæology is too well known to be stressed here. Its importance for British archæology is, if anything, even greater. The only area of western Europe which was never Romanized, not only contains the clue to all problems of free Caledonia, but Roman Britain, too, is not intelligible without the Keltic background, which can be unfolded by research in Ireland. No problem in Irish archæology can be solved without the British evidence; but is there any problem in British archæology which can be solved without Irish evidence ?

Tenth International Congress of Chemistry

THE Tenth International Congress of Chemistry met in Rome on May 15–21. More than thirty nations sent representatives, two thousand eight hundred in all; they included about seven hundred from Germany, two hundred from France and seventy-five from Great Britain.

Proceedings were opened at the Capitol in the presence of His Majesty the King of Italy with an address on the "Conquests of Chemistry" delivered by the president of the Congress, His Excellency Prof. N. Parravano of the University of Rome, and this was followed later by a reception by the Minister of National Education in the stadium of the Palatine—two sites of impressive and historic dignity.

The business of the Congress was conducted in the fine modern rooms of the recently built Citta Universitaria, in which the large hall set apart for the meetings was filled to overflowing during the opening addresses of the various sections.

Among those who opened the sections were Prof. P. Walden, on "The Creed of Scientific Chemistry"; Prof. C. N. Hinshelwood, on "Physical Chemistry and Modern Scientific Thought", delivered in fluent Italian; Prof. Swietosławski, on "Developments of Industrial Chemistry"; Prof. Jolibois, on "Transformation of Matter and Motive Power"; Prof. Giordani, on "The Utilisation of Thermal Energy"; Prof. Votocek, on "Synthesis of Carbohydrates"; Dr. Hissink, on "The Chemistry of Soils"; Dr. L. M. Lampitt, on "The Trend of Food Science"; Prof. E. von Euler, on "Vitamins and Hormones in Food and in the Human Organism"; Prof. Ruggli, on "Housing, Furnishing and Clothing in their Chemical Aspects"; Prof. Viviani, on "Natural and Artificial Textiles"; Prof. Fourneau, on "The Progress of Therapeutic Chemistry"; Prof. Butenandt, on "New Problems in Biological Chemistry"; Prof. Seyewetz, on "Chemistry and Photography"; Dr. S. E. Sheppard, on "Optical Sensitising of the Silver Halides"; Dr. Fr. ter Meer, on "New Developments in Chemical Technology"; Prof. G. Egloff, on "Petroleum—its Chemical and Industrial Significance"; Prof. D. M. T. Bogert, on "Chemistry and Defence"; Prof. H. Mark (not present) on a similar subject; Prof. Fr. Fischer, on "Chemistry and the Motor"; and Prof. Portevin, on "Metallurgy in Transport".

The President's opening speech and summaries of the above addresses in various languages were collected in a small volume and distributed at the end of the Congress, while in *La Chimica e l'Industria* for May (20, 251; 1938) will be found notes on the very numerous individual contributions to the sections together with photographs and short biographies of the presidents, vice-presidents and opening lecturers of each section.

Thus, not only was the Congress well organized, but it was also carefully documented. In addition to the above-mentioned documents, Prof. Parravano made a gift to the members of a valuable collection he had compiled of Italy's chemical achievements, "La Chimica in Italia" (535 pp. illustrated).

It was surely with pardonable pride that the Italians took pains that the sights of their incomparable city should be shown to the visitors. Opportunities were given for the Congress members to view the excavations of the Forum Romanum and the other fora recently opened up, and to visit the reclaimed Campagna. The excavations at Ostia and the Lido of Rome were visited, an expedition was made to the Villa d'Este at Tivoli and Frascati, and in Rome itself the Augustean Exhibition with its admirably arranged presentment of Rome throughout the ages was thrown open. For the ladies, tours were arranged daily to see in detail the churches, historical monuments, museums and villas of Rome.

For the efficient work of the secretariat only the highest praise can be given , frequent comment was made on the courtesy and instant helpfulness shown to members.

Among the social events must be mentioned the reception by the Governor of Rome, the symphony concert, the gala performance in the opera, at which were performed a new opera, "Il Rey" and, what will always remain in the memory of the visitors, "Cavalleria Rusticana" conducted by its composer, Mascagni, with Gigli singing the chief part.

Tours were arranged after the Congress and these included visits to chemical and electrochemical works, notably Prince Genori Conti's factories for boric acid and the production of carbide and cyanamide at Terni. Here enormous quantities of water-power are developed and used for the production of calcium carbide, which is converted into the fertilizer cyanamide by heating it in the presence of nitrogen obtained from fractionation of liquid air.

It will thus be gathered that the Tenth was a most successful Congress, in which was displayed the present state of knowledge in most branches of chemistry, in incomparable surroundings and with an abounding hospitality under the direction of the genial president, His Excellency, Prof. Parravano.

Among those from Great Britain and Eire attending the Congress were Sir Robert Mond, Sir William Pope, Sir Robert Robertson, Sir Gilbert Morgan, Profs. Donnan, Barger, Dillon, Dodds, Heilbron, Hinshelwood, Ingold, Nolan, Norrish, Robinson, Thorpe, Reilly, Dr. Fox, Dr. Lampitt, Dr. Jordan, and Messrs. W. A. S. Calder, A. Marshall and J. D. Pratt. The British visitors and the ladies with them met together at a luncheon and were entertained to dinner by Sir Robert and Lady Mond with their customary gracious hospitality.

The Eleventh Congress of Chemistry will be held in London in 1941 about the time of the celebrations of the centenary of the Chemical Society.

Towards the end of the Congress, the Council of the International Union of Chemistry met, and received reports from its numerous committees. President Parravano demitted his office, and as president of the Union for the ensuing term, Prof. M. T. Bogert, of Columbia University, New York, was elected. M. Jean Gérard, the very efficient secretary of the Union, was re-elected to that office.

R. ROBERTSON.

Obituary Notices

Dr. W. Eagle Clarke, I.S.O.

THE latter half of the nineteenth century saw the foundations laid of modern knowledge of bird migration, and Dr. Eagle Clarke was a leading exponent of the new methods in Great Britain. The idea that birds followed definite routes had stimulated fresh collection and study of records in Europe, and when the British Association for the Advancement of Science formed a Bird Migration Committee in 1880, Eagle Clarke was chosen to prepare the final reports, the last of which was presented to the Southport meeting in 1903. In the earlier days, intensive observation of the movements of birds in limited areas and co-ordination of results from many areas provided, the information upon which interpretation of migratory journeys depended, for bird-ringing was not tested as a scientific method until Mortensen's efforts in Denmark in 1899.

Eagle Clarke developed particularly two effective ways of studying migration. By living in lighthouses and lightships and by enlisting the services of lightkeepers he was able to catch bird movements in full swing, and his repeated visits during seasons of migration to Fair Isle, isolated between the Orkney and Shetland Islands, gave that tiny resting place something of the fame which Gatke's observations had already brought to Heligoland. The results of his observations were published in two volumes, "Studies in Bird Migration" (1912).

From the time of his first papers in 1879, Dr. Clarke added continuously to the knowledge of British birds, but he also found fresh material on ornithological excursions to Brabant, Slavonia and Hungary, the Pyrenees and the delta of the Rhone, Iceland and the Faroes, and identified collections from Jan Mayen, Franz Josef Land and Hudson's Bay, from the Philippines and the Antarctic voyage of the *Scotia*.

Most of Clarke's working life was spent in the service of the Royal Scottish Museum, Edinburgh, where he finally succeeded Dr. R. H. Traquair as keeper of the Natural History Department in 1906. He was responsible there for the modernizing and enlivening of the exhibits, and his all-round knowledge of the vertebrate groups set the high standard of mounting which characterizes the galleries of that Museum. In addition to the volumes already mentioned, he published jointly "A Handbook of Yorkshire Vertebrata" (1881), Bartholomew's "Zoogeographical Atlas" (1911), edited Colonel Wardlaw Ramsay's posthumous "Birds of Europe and North Africa" (1923), rewrote Saunders' "Manual of British Birds" (1927), and for many years edited the *Annals of Scottish Natural History* and its successor the *Scottish Naturalist*.

Dr. Clarke's work gained him many marks of recognition. He received the I.S.O. in 1920; the University of St. Andrews made him LL.D.; the British Ornithologists' Union chose him as the first recipient of the Godwin-Salvin Medal; and he was an honorary member of the American Ornithologists' Union and of the Ornithological Societies of Vienna and Budapest.

Dr. Clarke was born in 1853, he resigned his keepership in the Royal Scottish Museum in 1921, and after a long period of failing health he died on May 10, in his eighty-sixth year. He did a great deal to stimulate the study of animal life in Scotland, and there must be many who, like the writer, owe much of their interest in natural history to his enthusiasm and kindly encouragement. JAMES RITCHIE.

Dr. E. Goulding

DR. ERNEST GOULDING, who retired from the service of the Imperial Institute in 1935 when holding the post of vice-principal in the Plant and Animal Products Department of the Institute, died in London on February 15 in his sixty-eighth year. Born in 1870, the fourth son of the late William Purdham Goulding, of Finsbury Park, he was educated at Tollington Park College and at the School of the Pharmaceutical Society, Bloomsbury, which he entered as a Bell scholar. He graduated B.Sc. in the University of London in 1898, he took his D.Sc. (Lond.) degree in 1903, and was a fellow of the Institute of Chemistry, and also of the Chemical Society.

Goulding was intended for the profession of a pharmacist, but after his training at Bloomsbury and a period of research work at the School, in 1896 he joined as an assistant chemist the staff of the Scientific and Technical Department of the Imperial Institute under the direction of Prof. (now Sir Wyndham) Dunstan. For some years, he was engaged on the general work of the developing activities of the Institute, but before long he began to specialize in the study of cotton and of the hard and soft long vegetable fibres, in relation to the development of the production of these materials in Empire countries. The work on cotton, carried out in association with F. W. Barwick, was an important factor in the establishment of the now flourishing cotton-growing industries in Uganda and other British countries, and the early investigations of the long fibres proved of great value when Goulding took over the secretaryship of the Imperial Institute Advisory Committee on Vegetable Fibres which, with the assistance of the technical staff of the Institute, has done important work on these fibres, notably in the case of sisal. Goulding thus acquired an outstanding knowledge of vegetable fibres and wrote his "Cotton and other Vegetable Fibres" for the Imperial Institute series of handbooks. It was a great satisfaction to him that in 1936, after his retirement, he was invited to give the Mather Lecture of the Textile Institute, choosing as his subject "Textile Fibres of Vegetable Origin: Forty Years of Investigation at the Imperial Institute". It is mainly for his work on fibres that Goulding will be professionally remembered, but his long service in editing the *Bulletin* of the Imperial Institute must also be recorded.

As a research chemist, Goulding showed much ability, and he was fortunate in enjoying an early period of comparative freedom for such work before the development of technical investigation and administrative work absorbed his time. Jointly with Prof. Dunstan, he published between 1894 and 1901 a series of papers of which seven were concerned with derivatives of hydroxylamine. A study of the volatile oil of the bark of *Cinnamomum pedatinervium* formed his thesis for the D.Sc. (Lond.) and led to the publication of a number of joint papers on volatile oils prepared in collaboration with junior colleagues.

Goulding was a man of cheerful kindliness and modesty, combined with an unassuming firmness on matters of principle. He was active in Church work, being for many years vicar's warden and lay reader at St. Cuthbert's, Wood Green. He was much interested in Church music and also in Esperanto. He married twice: first, in 1905, Charlotte, daughter of the late William Larney of Finsbury Park, who died in 1907; and secondly, in 1908, Kathleen Irvine, elder daughter of the late Nathaniel Irvine Hawkes, of Crich, Derbyshire, who, with her son E. Irvine Goulding, survives him. S. E. C.

WE regret to announce the following deaths:

Prof. J. J. Abel, For. Mem. R.S., formerly professor of pharmacology in Johns Hopkins University, on May 26, aged eighty-one years.

Mr. G. S. Ram, O.B.E., formerly senior electrical inspector in the Factory Department of the Home Office, on May 21.

News and Views

Social Relations of Science

THE Council of the British Association has had under consideration the correspondence and leading articles which have recently appeared in NATURE on the subject of the "Social Relations of Science", and also a resolution forwarded from an informal meeting of those specially interested in the question, in which the Association was asked to establish within its own organization a special Department which would hold meetings, not necessarily confined to the annual meetings of the Association, to consider and discuss the social and international relations of science. The Council resolved to support this proposal, and appointed a committee to formulate a scheme giving effect to it, for presentation to the General Committee (with which the decision as to action will lie) at the forthcoming Cambridge meeting.

National Institute of Industrial Psychology

IT is a tragedy that, just when increasing attention is being given to the human factor in industry, the National Institute of Industrial Psychology, which, more than any other single institution in Great Britain, stands for the scientific study of the human factor in occupational life, should be threatened with disbandment after seventeen years of continuous and successful work. At least £2,000 is required to avert the Institute's disbandment, and to meet the expense of the Institute's unpaid national work a sum of not less than £6,000 per annum is required or an endowment which would provide this sum. In his presidential address to the British Association at its Blackpool meeting, Sir Josiah Stamp pointed out the anomaly of leaving to private support an enterprise of such outstanding national importance, and the situation becomes all the more anomalous in view of recent departures for the encouragement of research into social problems. The great services which the Institute has rendered to private firms through its fee-earning service should not be allowed to overshadow the importance of the work it has undertaken, sometimes voluntarily, for the departments of State, such as the Civil Service Commission, the Home Office (Prison Commission), Post Office, War Office, Admiralty, Royal Air Force, Ministry of Agriculture, Board of Education, Ministry of Labour, etc. Moreover, the experience gained in service rendered to particular firms in industry has itself a national value as providing a basis for further work and as giving to the whole of industry a new viewpoint on the value of applying psychology to working conditions.

THE supreme national importance of the work of the Institute is beyond question, whether in relation to the selection and training of staff for industry and commerce, the study of problems of environment and working conditions, causes of grievances and their removal and labour turnover, or in the wide field of vocational guidance. Much more work bearing on the national welfare still awaits it in all these fields and demands adequate financial support for this expansion. The present headquarters are cramped and inadequate for progress. For the needs of the immediate present and for future progress, for the new building and its endowment, £250,000 is required. To abandon the work already being done would be a national disaster, but our national status and prestige are no less involved in seeing that sufficient support is coming from all sides to ensure that the Institute is enabled to carry out and develop its work unhampered by financial stringency, so that it may give the full measure of service to national welfare which lies within its powers.

Statistics of Employment in Great Britain

ACCORDING to the report of the Ministry of Labour for the year 1937, for the second year in succession there was an exceptionally steep rise in the numbers of insured persons in the industrial field, the total, excluding juveniles under sixteen years of age and persons insured under the special agricultural scheme, reaching 13·4 millions, an increase of 350,000 on 1936. The increase was particularly marked in the age group 16–17, boys accounting for more than 50 per cent and girls for more than 80 per cent of the total net increases for their respective sexes. The total increase in the numbers of boys and girls during the last two years was more than 427,000, and it is a remarkable illustration of the improvement in industry that the whole of the new labour which has become available at these ages has been absorbed. The usual seasonal decline in employment was much less marked than usual, and thereafter the number of insured persons in employment increased steadily to a peak of 11,672,000 in August, when a change was made in the method of counting. Thereafter a slight decline in employment continued to the end of the year, the average level of employment for the year being about 500,000 higher than in 1936.

THE unemployment figures, except in December, were consistently below the 1936 totals, the average for the year being more than 250,000 below 1936, and the incidence of unemployment among insured workers fell from 12·9 per cent in 1936 to 10·6 per cent in 1937. Two fifths of the unemployed men are less than thirty-five years of age and a further two fifths more than forty-five years, the corresponding figures for women being three fifths and one fifth. A satisfactory feature of the year was that a high proportion of the improvement in employment occurred in the Special Areas.

Difficulty continued to be experienced in meeting the demands for certain types of skilled workers, notably in the building trade, engineering trade and in hotel employees and domestic servants. Reference is made in the report to the popularity of the physical training classes for the unemployed as well as to an increase in the number of areas affected by a shortage of juvenile labour, particularly in the age group 14–15. In many districts the shortage was due not only to lack of supply but also to the reluctance of parents to allow their children to take certain types of employment. Attempts made by employers to overcome the shortage included the employment of older juveniles, substitution of girls and young adults for boys and the creation of new opportunities for boys to be absorbed into the adult branches of trades. Although some trades in which apprenticeship is a common method of recruitment showed an increase in numbers, notably engineering and shipbuilding, there was no sign of a general revival of the system of apprenticeship.

Science and the Soviet Fisheries

THE progress of the Soviet fishing industry and the part played therein by science are graphically illustrated at an exhibition opened in the new building of the All-Union Institute of Sea Fisheries and Oceanography in Moscow. Various exhibits show the means by which the catch of sea fish has been almost doubled in recent years, reaching 1,650,000 tons in 1937. A big modern fishing industry, equipped with up-to-date canneries, cold-storage facilities, refrigerator vessels and a fleet of trawlers, has been built up in the last twenty years. The production of tinned and frozen fish during the first and second five-year plans has been trebled, while the output of smoked fish is twenty-three times its former figure. An important feature in the development of the Soviet fishing industry is its extension to new regions. Before the Revolution, the Caspian and Azov Seas were the main fishing centres. To-day, an extensive fishing industry has been built up in the Far East and in the White and Barents Seas. The Far East has 41 canneries, with an annual output capacity of 150 million tins, as well as large floating crab canneries and a whaling fleet. The growth of the fishing industry in the White Sea is illustrated by the fact that the catch in the Murmansk Region last year was nearly 280,000 tons, as compared with 13,000 tons in 1913.

THE development of the Soviet fishing industry has called forth a corresponding development of scientific research in this field. Before the Revolution, there were only three scientific stations to serve the industry. To-day, scores of scientific institutes, stations and laboratories are studying problems relating to fishing. The All-Union Institute of Sea Fisheries and Oceanography, which directs all the scientific work in this field, is an institution the annual budget of which runs into 16 million roubles. Special interest is attached to a section of the exhibition showing the work of Soviet men of science beneath the surface of the sea. For two years, scientists, descending to the bottom in divers' suits, have been studying the delta of the Volga, the northern part of the Caspian and of the Sea of Azov, determining the location of schools of fish and their movement and observing the working of the nets. A bathysphere for the study of sea bottoms at great depths, a model of which is on display, is now under construction. Soviet men of science are introducing new methods in the processing of fish. The time required for salting has been reduced from two days to just a few seconds by the introduction of a method whereby brine is injected into the fish.

Phenology of 1937

THE Royal Meteorological Society has produced its annual phenological report at a welcomed early time this year, and Major H. C. Gunton, who is responsible, for the first time, for it, has not only made this issue to observers in April (which enables a convenient comparison with the following year upon which observations are beginning) but also considerably improved and altered the arrangement of the mass of details in the report, a number of very detailed and somewhat complicated graphs producing a better comparison between meteorological events and plant, insect and bird records than was hitherto possible without considerable detailed study. The records of the report chiefly show the lateness of wild-life in the colder and early-wetter and later drier-than-usual weather of 1937. The sudden departure of swifts in early August is of importance, for whatever the reason, it was true that the majority of swifts left the country during a rise in temperature, and the same thing happened in the last drought year; they left before the hottest day of the first heat-wave in early August. Because of the mildness, seed and berry-eating bird winter visitors, like redwings and fieldfares, were few early in the winter; the March cold caused an influx of waxwings in the north and siskins in the south. After a south-west gale, a wave of incoming migrants was noted on May 23, and on the whole, summer migrants left early.

Royal Meteorological Society: Phenological Studies

THE Royal Meteorological Society has circulated its 500 odd phenological observers in the British Isles a description of a new organization for phenological-ecological research, so that the observations will have an increased specialized value for the various subjects undertaken. The organization consists of the Royal Meteorological Society, Royal Entomological Society, British Ecological Society, South-Eastern Union of Scientific Societies, the Natural History Museum, Ministry of Agriculture and Fisheries, Bureau of Animal Population, Rothamsted Experimental Station, Society for British Entomology, British Ornithologists' Union and the British Trust for Ornithology. An executive committee will have power to co-opt additional specialists and set up panels to deal with separate branches of observational work, as migration, etc. It is hoped to explore locally as well as nationally the possibility of further collaboration of botanist, ornithologist and entomologist for the more accurate observation of the different subjects under identical climatic conditions. H. Fairfield Smith, of the Galton Laboratory, University College, London, also makes his report of the preliminary statistical investigation of the flowering dates of plant records in the Phenological Reports of the Royal Meteorological Society (*Quart. J. Roy. Met. Soc.*, Jan. 1938) showing the standard deviations in restricted localities appear to be about 5–7 days for late spring and summer plants, rising to 13 days for early spring and autumn flowering plants. The country-wise standard deviation of locality means for hazel and hawthorn in 1933 was about 4–5 days, and regression of flowering date on altitude about 1·3 days per 100 feet. Temperature appears to be the dominating meteorological factor determining flower dates, which vary within a locality as a function of climatic as well as of individual plant and environmental factors.

Smithsonian Archæological Expeditions

Two expeditions of the Smithsonian Institution of Washington, it is announced, have taken the field for the operations of 1938. Dr. F. H. H. Roberts, jun., has left for the Lindenmeier site in northern Colorado, where he will continue his work of excavation on the camp site once occupied by Folsom man; and Dr. Aleš Hrdlička is on his way to the Aleutian Islands, where he will carry further the archæological and ethnological investigations on which he has been engaged on behalf of the Smithsonian Institution in each year since 1926, with the object of determining the character and course of the early migrations of man to the American continent. It will be remembered that Dr. Hrdlička, after devoting several seasons to the Eskimo problem, and the succession of cultures in the far north, has in his recent expeditions turned to the Aleutian islands, which he regards as one of the original migration pathways into North America. Here he has found in the craniological material excavated evidence of two distinct types of man, of which the later is distinguished from the earlier by an increase in the breadth of the skull, just as he had found two forms of Eskimo skull, also differentiated by an increase in breadth in the later type. The evidence as a whole, he maintains, points to the fact that all this northwestern region of the continent was a "nursery of peoples", constituted by several related strains of Asiatics, from which either the pronounced Eskimo or the typical Indian could easily have developed.

Dr. Roberts's problem is also concerned ultimately with the question of the character of early man in North America, for one of the main objectives of the fourth season's excavation on the Lindenmeier site will be an intensive search for the skeletal remains of Folsom man, of which no trace has as yet been found on any of the several sites which have been investigated by various explorers. Further, a change in orientation in the study of the Folsom culture may be necessary. Hitherto it has been accepted that Folsom man followed the bison which in turn, followed the retreating glaciers northward to take advantage of the pasture which sprung up behind the melting ice. The recent discovery of what are believed to be relics of the Folsom hunters so far north as Saskatchewan, and of the same date as the Colorado culture, is difficult to reconcile with the hypothesis most generally held that at this period the region in which these northern relics have been found was covered with glacial ice some hundreds of feet thick. This discovery would appear to lend support to the theory of some geologists that an ice-free corridor extended from Alaska southward, in which vegetation was probably dense, and in which men and animals migrated freely.

Studies of the Later Iron Age

Although it is a commonplace that archæology is a 'young' science, this can be appreciated in its fullest implication only when a comprehensive survey is made of some one department of archæological studies such as that of the La Tène culture in Mr. J. M. de Navarro's Sir John Rhys Memorial Lecture for 1936 before the British Academy ("A Survey of Research on an Early Phase of Celtic Culture", Humphrey Milford, pp. 42, 1937. 3*s*. net). The La Tène culture, especially in its artistic manifestations, has so high a place in the development of protohistoric studies, and has been the subject of so much detailed investigation, which is recorded in a considerable literature, that it is difficult to realize that La Tène, the later of the two type stations or rather sites which have given their names to the principal divisions now recognized in the Iron Age, was first investigated so recently as 1856, though sites and objects now regarded as belonging to that civilization were being discovered for some years before.

The credit of recognition of the full significance of La Tène belongs to Sir A. Wollaston Franks, whose contribution to John Kemble's "Horae Ferales" (1863), discussing a series of La Tène objects, was the first to envisage the ethnical aspect of that civilization in its true light, although Thurnham in "Crania Britannica" (1857) had already grouped together certain La Tène metal types as 'Late British' and assigned them to a bronze and iron transition period. It was, however, Franks who first recognized the geographical extension of the La Tène culture and identified it with the Celts. Among later contributors to the archæological aspect of Celtic studies, to whom Mr. de Navarro refers, three names stand out—Sir Arthur Evans, for the account of his excavation of the Late-Celtic urnfield at Aylesford, Kent (1890), and Paul Reinecke, to whom is due the first comprehensive survey of La Tène culture (1902); but in the remarkable recent development of archæological study of the later Iron Age, of which Mr. de Navarro takes account, the influence is pre-eminent of J. Déchelette, whose "Manuel d'Archéologie Celtique" appeared in 1914, and whose untimely death in the Great War is still mourned as one of archæology's gravest losses in that struggle.

Mummification Technique in Ancient Egypt

A PIECE of evidence bearing on the methods and apparatus in use in the processes of mummification in ancient Egypt, but which apparently has suffered neglect, has been rescued from the rest-house of the Department of Antiquities at Medinet Habu, where it has remained in the garden for many years, and has been placed in the Cairo Museum (*The Times*, June 6). It is a limestone table, on which the operation of embalming took place, and is officially described as unique. It measures eight feet five inches long by three feet four inches wide, and resembles the traditional form of the bed on which mummies were exhibited at funerals. Representations of the legs and feet of lions are carved in relief at the corners, and at the head were lions' heads similarly carved. A raised border surrounds the table, and at the foot, where the feet of the body lay, there is a sufficient depth to allow for the retention of several quarts of the embalming liquid. A small hole pierced at the end of the table allowed the liquid to be drained away from a semi-circular basin-like depression. The table is eleven and a half inches only in height, and it is therefore assumed that the embalmers worked in a squatting position.

Astronomical Exhibits

ON April 27 a number of astronomical exhibits were on view at the meeting of the British Astronomical Association held at Zion College. It would be impossible to describe all of these, but three were of sufficient interest to merit short notices in the May issue of the Association's *Journal*. Mr. D. A. Campbell showed an ingenious drive for small telescopes. This consisted of a sand-clock, a device at the base of the apparatus regulating the flow of well-sifted silver-sand. A piston of lead rested on the top of the sand, and this, as it sank, pulled a cord which finally actuated the driving shaft of the telescope. Dr. J. L. Haughton exhibited a microscope which measured star images. The main object of the instrument was to determine stellar magnitude by measuring the diameter of the photographic images, and for this purpose an accurately machined screw thread just over 1 cm. in length was used. Mr. A. Coleman showed a solar eyepiece attachment, and has a fairly long description of the apparatus, which should be read by those who are interested in solar work. It minimizes certain disadvantages which are inherent in the usual combination of a solar diagonal with a suitable dark glass over the eyepiece.

Iodine Educational Bureau

THE Nitrate Corporation of Chile Ltd. is organizing an Iodine Educational Bureau to promote the knowledge and use of iodine in the agricultural, medical and industrial fields. It collects all available scientific information in respect of iodine, and the information will be placed at the disposal of the medical profession and scientific agricultural circles, as well as commercial interests, including feeding stuffs manufacturers and livestock breeders. In addition, the Bureau will collaborate with scientific institutions in experimental research to extend the knowledge of iodine, with special reference to its use in human and animal nutrition. It will not engage in any selling activities. The Bureau will be under the direction of Dr. Francis C. Kelly, who has been associated with Sir John Orr for the past six years as deputy director of the Imperial Bureau of Animal Nutrition at the Rowett Research Institute in Aberdeen. Dr. Kelly is a graduate of the University of Aberdeen. Following two years in the Colonial Service as biochemist to the Medical Department of Kenya Colony, he became technical adviser to the Chilean Iodine Producers' Association in 1928. In 1930 he was appointed a member of the Iodine Estimation Sub-committee of the Medical Research Council of Great Britain. When the Imperial Bureau of Animal Nutrition was established in 1932, Dr. Kelly was appointed deputy director. He is also secretary of the international abstracting journal, *Nutrition Abstracts and Reviews*. Dr. Kelly will become director of the Iodine Educational Bureau in September. His technical assistant will be Miss Ethelwyn M. Mason, of the New Zealand Department of Agriculture, who has been carrying out iodine research work at the Rowett Institute since 1934. The offices of the Iodine Educational Bureau will be at Stone House, Bishopsgate, E.C.2.

'Dowtherm'

DURING the Great War, synthetic phenol was manufactured by sulphonating benzene, but a continuous process for vapour phase chlorination has been employed at the Dow Chemical Co.'s works in the United States for some time now. The chlorobenzene is afterwards hydrolysed with caustic soda and some diphenyl oxide is obtained as a by-product. Diphenyl oxide has a melting point of 27° C. and in order to be useful as a commercial fluid for heat transmission it must not set solid in the piping when the plant is allowed to cool. Although diphenyl has a melting point of 70° C., yet a eutectic mixture, known as 'Dowtherm', consisting of 26·5 per cent diphenyl with diphenyl oxide, melts at 12° C. This compound can be used for heating purposes in a similar manner to steam but with the additional advantage of higher temperatures for the same pressure. The boiling point at atmospheric pressure is about 258° C. and at 135 lb. per square inch gauge pressure it gives a temperature of 400° C. against 181° C. for steam. At 370° C. the temperature can be controlled to within about 1° C. by simply manipulating a throttle valve. The use of condensing vapour for heating results in considerable economy in plant design since the hot liquids in use hitherto have very low heat transfer coefficients. The vapours are not toxic, although leaks can be readily detected since the vapour is exceedingly pungent. It gives a means of accurately controlling the reaction temperature in the manufacture of dye intermediates and is used in the distillation of fatty acids and glycerine, the deodorization of edible oils, the evaporation of caustic soda, the processing of varnishes, the saponifying of greases and the melting of asphalts and bitumen. Owing to the low surface tension and viscosity of Dowtherm, all joints have to be made extremely carefully. The licence for development in Great Britain is held by Messrs. W. J. Fraser and Co., Ltd., of Dagenham, Essex.

Norwegian Arctic Research

It was some ten years ago that the Norwegian Government, having acquired by treaty the sovereignty of Spitsbergen, instituted a department to deal with the scientific exploration of Spitsbergen, Bear Island and other arctic regions, including areas outside Norwegian jurisdiction. This department, Norges Svalbard-og Ishavs-Undersokelser, under the direction of Dr. A. Hoel, has now published a record of the ten years of its activity (*Skrifter om Svalbard og Ishavet*, No. 73). Earlier Norwegian work was recounted in a previous publication (No. 1, *loc. cit*; 1929). Almost every summer expeditions have been at work in Spitsbergen and East Greenland and occasionally in other islands, as Jan Mayen, Bear Island and White Island. In Svalbard (Spitsbergen, North-East Land, Bear Island, etc.) 560 sq. km. have been mapped on the land and 40,000 sq. km. from the air, and in East Greenland 9,200 sq. km. and 30,000 sq. km. In addition, large areas of the arctic seas have been charted and much oceanographical work accomplished. But no aspect of research has been overlooked, and the department has even erected navigation beacons and lights and introduced the musk-ox and the arctic hare to Spitsbergen. Winters have been used for working up results, and already the publications of the department number over seventy. The greater part of the cost is met by a State grant, but private contributors also help. The volume makes a fine record of careful scientific work.

Electrical and Allied Industries Research Association

The seventeenth annual report of the British Electrical and Allied Research Association (E.R.A.) proves that the research scientific worker is becoming indispensable to the industry. It is his work that enables the producer to acquire new principles, data and methods which he can embody in his technique and products. The producer passes these benefits on to the distributor, and finally the consumer derives benefits from greater efficiency, trustworthiness and utility. The work enables the industry to gain substantial immunity from breakdowns and the consequent and ever-present risk of black-outs and extensive damage. The activities of the Association are expanding very satisfactorily. Nearly half the research work of the E.R.A. is now conducted by its own staff. Its success is built up largely upon the gratuitously given labours of its eighty committees comprising about 500 voluntary workers. It carries out researches in co-operation with many scientific and engineering institutions. The principal income of the Association consists of the following annual grants: Department of Scientific and Industrial Research, £24,500; electricity supply undertakings, £32,932; manufacturers, £19,737. In addition, the Institution of Electrical Engineers gives £1,000 and so also does the B.B.C. The accounts show a surplus for the year of £13,500 after transferring £5,000 to the reserve account, but it is pointed out that practically all this sum is already required in connexion with particular researches in hand and is not available for next year's commitments. The Department of Scientific and Industrial Research and other important contributors are urging the Association to establish a more adequate reserve.

The Belfast-Stranraer Telephone Cable

In 1853, the British and Irish Magnetic Telegraph Company laid a cable between Port Patrick and Donaghadee. This cable proved to be successful and was one of the forerunners of the Atlantic cable in laying which Lord Kelvin played a leading part. Until last year, the telephone and telegraph traffic had been carried by four telegraph cables laid in 1870, '79, '88 and '93 for telegraph working but afterwards converted to telephone working, and a 'continuously-loaded' cable made in 1921. In addition, a loaded cable connects Blackpool to the Isle of Man and thence to Ballyhornan, Northern Ireland. These cables were made by Siemens Brothers and Co., Ltd., and its associated company, Submarine Cables, Ltd., which claim to be the only British organization that undertakes the design, manufacture and installation of all types of submarine and land cables as well as the necessary carrier-current equipment. In the Engineering Supplement to *Siemens Magazine* of January a description is given of two more submarine cables completed last September, their opening coinciding with a special low charge for calls carried by submarine cable to Northern Ireland. As each of these cables can carry four calls simultaneously, there are eight circuits available to help carry the increased traffic brought about by the tariff reduction. It is possible to increase further the carrying capacity by the addition of more carrier equipment. One of the two new cables serves for transmission from Belfast to Stranraer and the other cable for transmission in the opposite direction. In addition to the submarine cables, there is a radio link connecting Ballygomartin, near Belfast, and Port Patrick.

The New Commonwealth Society

The annual report of the New Commonwealth Society for the year ended September 30, 1937, refers to considerable progress in the development of international sections, new groups or sections having been formed in the United States, Austria and Czechoslovakia, and arrangements made for the Swiss Europa Union to perform the functions which would otherwise be carried on by a Swiss Section of the Society. The existing groups in Germany and Hungary have been considerably developed, and development in other countries during the period has to some extent outpaced the progress of the British section. Disappointing results have followed the introduction of facilities for the enrolment of group associate members, but the first international conference organized by the Society, held at Pontigny, August 13–23, was an outstanding success, as was a New Commonwealth Society Youth Camp at Llandinan in August, which included German, Dutch, Czechoslovakian, Norwegian, Hungarian, Greek, Swiss and British representatives. Four new pamphlets were issued during the year, and the British Section concentrated its attention on an attempt to lay the foundations of an area organization throughout Great Britain. The report of the New Commonwealth Institute for the same period refers to the initiation of a Monthly Information Bulletin and to the formation of four special research committees, dealing respectively with legal, military, political and psychological questions. The Legal Research Committee adopted as a basis for its discussions Prof. Strupp's study and proposals for an International Peace Convention, and considerable progress has been made in the establishment of an adequate research library on problems of peaceful change and collective security.

Journal of Pomology and Horticultural Science

In view of the increasing number of contributions to the *Journal of Pomology and Horticultural Science* received from overseas, it is felt that the scope of the journal, hitherto the official organ of the Long Ashton and East Malling Research Stations, should be extended to provide a medium for the publication of the results of horticultural research of wider interest. The editors have accordingly obtained the services of the following as associate editors: M. B. Davis, Central Experiment Farm, Ottawa, Canada; Dr. C. Barnard, Division of Plant Industry, Council for Scientific and Industrial Research, Canberra City, F.C.T., Australia; L. W. Tiller, Department of Scientific and Industrial Research, Wellington C.1, New Zealand; Prof. E. E. Cheesman, Imperial College of Tropical Agriculture, Trinidad. Intending contributors overseas are asked to submit their papers in the first instance to the associate editor in their respective countries.

Agricultural Research

The annual volume for 1937 of the *Journal of the Royal Agricultural Society of England* has now been published and includes as in recent years the "Farmer's Guide to Agricultural Research". The latter has been a feature of the Society's publications for the past twelve years, and consists of a number of valuable summaries of recent research work in the leading branches of agriculture, each section being prepared by an acknowledged expert on the subject. The various sections and the authors responsible for them are the same as in the previous issue. Space does not allow of reference to all the many interesting articles in this number of the journal, but mention may be made of the account of two centuries of Cheshire cheese farming, which gives a vivid and often humorous picture of agricultural life in England during the period under review. The Leckford Estate, Ltd., forms this year's subject in the series of notable farming enterprises.

Polar Exhibition

A preliminary circular has been issued of the projected International Exhibition of Polar Exploration which is to be held at Bergen from May until September, 1940, under the patronage of the King of Norway and the presidency of the Prime Minister, the Ministers of Foreign Affairs and Commerce and the chairman of the council of the city of Bergen. The aim is to present a general survey of exploration, natural conditions and inhabitants and resources in arctic and antarctic regions. Polar regions of all States are to be included. Exhibits will consist of charts, models of vessels and aeroplanes, instruments, equipment, diaries, photographs and paintings. Whaling, sealing, trapping and tourist traffic will also be represented. Buildings are to be erected for the exhibition, which will be held contemporaneously with a national exhibition of arts, crafts, fisheries and communications. The offices of the Polar Exhibition are Telegrafbygningen, Bergen, Norway.

National Baby Week Council and Physical Fitness

The National Baby Week Council holds, and rightly so, that "physical fitness begins in the maternity and child welfare centre", which will be its slogan for this year. The centres cater for the well-being of the expectant mother, the nursing mother, the infant and child up to five years of age. A good start towards physical fitness can, and should, be given in those centres. The Council emphasizes that physical fitness cannot be obtained by physical exercise alone, and that nutrition, better housing and other reforms also bear a close relation to the whole problem. The Council will gladly advise representatives of organized bodies, or any individual requiring advice. Correspondence should be addressed to the Secretary, National Baby Week Council, 117 Piccadilly, London, W.1.

British Health Resorts Association

A new edition of the official handbook of the British Health Resorts Association has recently been issued (British Health Resorts—Spa, Seaside, Inland; including those of the British Dominions and Colonies. London: J. and A. Churchill, Ltd. 2*s.* 6*d.* net). The publication gives a brief, authoritative and impartial account of British health resorts, as contrasted with the purely holiday resort. The book is supervised by a medical advisory committee, contains a chapter on "Climate, Health and the British Resort", and gives general information which will enable medical men and their patients to make their choice of a suitable place.

National College of Physical Training

A site of more than two hundred acres on high ground at Merstham, Surrey, has been selected for the National College of Physical Training, which is to be erected under the Physical Training and Recreation Act for the purpose of training teachers and leaders. The land is protected on all sides from building encroachment, not only by natural features, but also, through the foresight of the local authorities, by town planning schemes, while close by are areas acquired in connexion with the 'Green Belt'.

Scholarships for the Study of Tuberculosis

THE Italian Fascist National Federation against Tuberculosis has placed at the disposal of the International Union against Tuberculosis six scholarships at the Carlo Forlanini Institute in Rome. These scholarships are of the value of 2,000 lire each, plus board and lodging, and are intended to enable foreign medical practitioners to study at the Carlo Forlanini Institute. They will be awarded by preference to young physicians already familiar with tuberculosis problems who wish to improve their knowledge of this branch of medicine. Candidates should send their names, ages, qualifications and professional experience to the Secretariat, Union internationale contre la Tuberculose, 66 Boulevard St. Michel, Paris, not later than July 1.

Royal Society of Arts: Prizes for Navigation

THROUGH the Thomas Gray Memorial Trust, the Royal Society of Arts offered last year a prize of £75 for an invention, publication, diagram, etc., which was considered to be an advancement in the science or practice of navigation, proposed or invented in the period January 1, 1932–December 31, 1937. Thirty-six entries were submitted. The judges were of the opinion that none of the inventions put forward was deserving of the full prize, but they decided to make the following awards: £25 to W. Sommerville, of Benton, Northumberland, for his system of instruction and examination in the rule of the road at sea; £25 to Lieut.-Commander P. V. H. Weems, Annapolis, Maryland, U.S.A., for his second-setting watch. A prize of £25 for an essay on "The Stability of Ships" has been awarded to H. David, of Ely, Cardiff. The following prizes are offered for 1938: a prize of £25 for an invention, publication, diagram, etc., which is considered to be an advancement in the science or practice of navigation, proposed or invented in the period January 1, 1933–December 31, 1938; a prize of £25 for an essay on a navigational subject. Further information can be obtained from the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.2.

Announcements

SIR ALDO CASTELLANI has been elected an honorary member of the Hanseatic University of Hamburg.

DR. FRIEDRICH PASCHEN, professor of experimental physics in the University of Berlin, has been made an honorary member of the Rumanian Academy at Bucharest.

A PORTRAIT MEDAL designed by Dr. Robert Tait McKenzie, Canadian physician and sculptor, has been struck to celebrate the fiftieth anniversary of the foundation of the American Society of Anatomists in memory of its first president, Joseph Leidy, who died in 1891.

AN Order of Public Health has been created by a decree of the French Government, to be awarded by the Ministry of Health to those who have made outstanding achievements in public health or social service. It will consist of the three ranks of knights, officers and commanders.

THE eighth International Congress of Military Medicine will be held at Luxemburg on July 1–4. In addition to the usual discussions on military medicine, the following subjects will be dealt with: (1) legislation on aerial protection; (2) scientific study of aerial protection; (3) demonstration of medical aviation.

THE National Institute of Industrial Psychology's vacation course in psychological methods of vocational guidance will be held on August 1–13 at the London School of Economics, where a course will also be held during the same period on the administration of Binet-Simon tests of intelligence. The fee for the former course is five guineas and for the latter course three guineas. Further information can be obtained from the Secretary of the Institute of Industrial Psychology, Aldwych House, W.C.2.

THE summer meeting of the American Association for the Advancement of Science will be held in Ottawa on June 27–July 2. Science and Society Conferences are being organized by the Section on the Social and Economic Sciences, under the general direction of Dr. Harold G. Moulton, and the first conference was held at Indianapolis last December on the subject "Fundamental Resources as Affected by Science". The subject of the Ottawa Conference will be "Science and the Future".

THE programme of the summer school in physics to be held at the University of Reading under the auspices of the Institute of Physics on July 7–9 has recently been issued. The following lectures will be given, and these will be followed by discussion: Prof. J. A. Crowther, "Physics in Biology"; Dr. C. E. Wynn-Williams, "Some Electronic Devices and their Applications"; Dr. O. Klemperer, "The Theory and Practice of Electron Optical Devices"; Dr. E. A. Guggenheim, "Thermodynamics of Low Temperatures"; Dr. W. F. K. Wynne-Jones, "The Significance of Interfacial Potentials"; Dr. C. G. Sumner, "Interfacial Potentials in Systems of Industrial Importance". Membership of the School is open to all interested. Further information can be obtained from the Secretary, Institute of Physics, 1 Lowther Gardens, Exhibition Row, London, S.W.7.

WE are informed that the brochure entitled "The Story of Vitamin B_1", referred to in NATURE of June 4, p. 1006, is issued by Messrs. Merck and Co., Inc., of Rahway, New Jersey.

ERRATUM.—The great eruption of Mt. Pelé on May 8, 1902, referred to by Dr. C. T. Trechmann in NATURE of March 12, p. 435, occurred at 8 a.m., not 8 p.m. as stated.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1060.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Thermal Conductivity at Low Temperatures

IN continuation of our experiments on quartz and potassium chloride[1], Mr. Biermasz and I have determined the conduction of heat in quartz crystals of varying dimensions. (A complete account of this work will appear in *Physica.*) The object of the investigation was to study the dependence of the conductivity on the dimensions of the crystal[2]. It was found that both in the case of potassium chloride and silica (at temperatures 2·5°, 2·9° and 3·3° K.) the heat resistance is a definite function of the radius R; when R tends to zero the resistance becomes infinite more quickly than $1/R^2$, or in other words, the 'specific' resistance becomes infinite. With increasing thickness, on the other hand, the specific resistance approaches a constant value asymptotically; for potassium chloride this value is almost reached for $2R \sim 1$ cm.; for silica this will be the case for $2R \sim 3$ cm.

It is not astonishing that such an asymptotic value is reached. If there were no scattering of the elastic waves at all, then it would be impossible to establish a temperature gradient in the crystal and the conductivity would be infinite[3]. In order to obtain a finite temperature gradient, one has to assume that the elastic waves are scattered, and with increasing cross-section of the rod the scattering by the surface of the cylinder will gradually become less and less important relative to the scattering in the bulk of the material. We will assume that the resistance is due to scattering by the surface, scattering by the mosaic structure and to scattering of the elastic waves by one another. Further investigations will be needed to show the part played by each of these factors separately.

It seems interesting to investigate the behaviour of thin rods of metal and to see whether a separation of electronic conduction and lattice conduction can be effected, and whether a correlation between these conductivities can be found.

Neutron-Electron Interaction proposed by Kikuchi

IT is known that a Geiger-Muller counter operated near a source of fast neutrons gives a rather large number of counts. Kikuchi, Aoki and Husimi[1,2], working with a D-D source of neutrons, have postulated that these counts arise in part from a direct interaction of fast neutrons with electrons in the thin lead foil surrounding their counter. However, the recent discovery by Kallmann and Kuhn[3] that gamma-rays are emitted in the D-D reaction seems to offer a simple and more satisfactory explanation for the phenomena observed by Kikuchi and co-workers. Confirmatory evidence is the discovery by Bonner[4] of two groups of neutrons from the D-D reaction.

Even when the gamma-rays from a D-D source are absorbed with lead[5], or when a radium-beryllium source of neutrons is used with a sufficient thickness of lead to remove the primary gamma-rays from the source[6], a counting rate much in excess of the natural background of the counter is observed. We have shown that two thirds of the counts caused by a radium-beryllium source of fast neutrons, suitably enclosed in lead, can be accounted for by the gamma-rays excited in lead by the inelastic scattering of fast neutrons. An appreciable part of the remaining third will be due to recoil nuclei within the counter gas. Internal conversion of the gamma-rays produced in the lead foil surrounding the counter (and in the iron wall of the counter) can account for the remainder of the counts only if one assumes an average internal conversion coefficient as large as 15 per cent. In a study of the radiation accompanying thin, non-radioactive, gamma-ray sources, we find, however, that internal conversion coefficients of this magnitude do occur in the heavier elements for gamma-rays of moderate energy. Recent experiments by Alvarez[7] also lead to internal conversion coefficients larger than those previously expected.

Takeda[8] also studied the counts caused by the neutrons from a radium-beryllium source surrounded by a large block of lead. He concluded that less than half his observed counts could be accounted for by the gamma-rays excited in the lead block by the neutrons, and hence that the direct interaction of neutrons with electrons proposed by Kikuchi and co-workers was responsible for the remainder of the counts. However, he failed to correct for the decrease in the natural background of his counter caused by the test lead (placed above the counter) which he used to estimate the fraction of the counts which were due to gamma-rays excited in the lead block. When such a correction is made, the results of Takeda appear to be in agreement with our own.

Sodium in the High Atmosphere

BERNARD has described in NATURE[1] his observations proving that the yellow radiation of the night sky and of the twilight-sky, 5893 A., can be identified with the two sodium *D* lines. With regard to this communication we wish to make the following comments:

(1) Attribution of the yellow radiation at night to the sodium was examined for the first time by Dufay[2]. Interstellar sodium was first in question, but rough measurements of the ratio of intensity at the zenith and near the horizon, and, in particular, the variation of intensity from night to night, brought evidence that the radiation was emitted in the upper atmosphere. Furthermore, a long series of observations made by Garrigue[3] at the Pic du Midi put the atmospheric origin of the yellow radiation beyond all doubt.

(2) After further observations made at Montpellier, Cabannes and Dufay[4] pointed out the probable complexity of the 5893 radiation. In the same paper, the authors examined the hypothesis of an emission by sodium atoms in the atmosphere and announced that interferential analysis was in progress.

(3) Increasing intensity of the yellow radiation at twilight had been previously discovered by Currie and Edwards[5] at Chesterfield (Canada), during the International Polar Year, 1932–1933. Bernard[6] attempts to show that the observations of Currie and Edwards did not concern the 5893 radiation. The wave-length measured by Currie and Edwards was indeed 5940 A., but their measurements were not precise and they concluded that "this radiation is due to a luminescence distinct from the aurora and is probably the radiation 5893 A. observed by Vegard and Tönsberg in the night-sky light". Bernard's argument, therefore, does not seem convincing to us.

(4) We have analysed the yellow radiation at night and at twilight, following two different methods:

(*a*) A Fabry-Perot interferometer was adjusted in front of a small two-prism spectrograph of which the camera lens has a relative aperture *F*/1 and 25 mm. focal length. A lens of 6 cm. or 10 cm. focal length projects the fringes on to the slit. With exposures of 20 hours or more, at night, we have observed very crowded fringes on the yellow radiation. The aspect of these fringes was exactly the same as that of the fringes given by the sodium flame. The first positive result at night was thus obtained with a 27-hour exposure between February 28 and March 4, 1938.

We have carried out the same experiments at twilight, when interferential analysis of the 5893 radiation is much easier than at night, because of its stronger intensity.

(*b*) At the same time, a second Fabry-Perot étalon was used without a spectrograph, and placed in front of a camera lens of 25 mm. focal length and relative aperture *F*/1. An orange filter (Schott glass *OG*2, 2 or 4 mm. thick) absorbs the green line 5577 A. In order to be free from the red line 6300, plates of which the sensitiveness is small at 6300 were used. Interferential fringes were thus photographed at twilight with exposures of 15–30 minutes. Using alternately air spaces of 0·30 mm. and 0·15 mm. thickness between the half-silvered surfaces, one or two systems of fringes appeared. In every case their diameters differed by almost 0·01 mm. from the diameters of the sodium fringes photographed on the same plate. The D_2 fringes are, as in the laboratory, about twice as intense as the D_1 fringes.

Bernard's observations are identical with our own, when following this second method. Our results[7] were communicated to the Academy of Sciences at the same meeting, March 21, 1938, as those of Bernard. Interferential fringes photographed at night without the use of a spectrograph are then weak, but, some days later, fringes obtained at night with a 22-hour exposure were as strong as those taken previously at twilight.

In conclusion, we wish to point out that the identification of the sodium *D* lines in the atmosphere, suggested by our previous experiments, was made simultaneously by Bernard and ourselves.

Adsorption of Gaseous Mixtures at Solid Surfaces

IN a recent paper[1], the statistical mechanics of gaseous adsorption at solid surfaces has been developed using the method of partition functions. The imperfection of the adsorbed phase was taken into account and adsorption isotherms appropriate to various models of the adsorbed phase were developed.

The method can be extended quite simply to gaseous mixtures. The partition function for a gaseous system consisting of N_1 molecules of a gas *R* and N_2 molecules of a gas *S* is

$$H(\theta) = \{h_1(\theta)\}^{N_1}\,\{h_2(\theta)\}^{N_2}\,B(\theta),$$

where $h_1(\theta)$ and $h_2(\theta)$ are partition functions for the molecular internal and translational energies of *R* and *S* respectively, and $B(\theta)$ is the partition function for the potential energy of the whole system; which includes not only the volume term but also a term which accounts for the potential energy of those molecular interactions which are responsible for gaseous imperfection. For a gas mixture in a potential field φ, we can write

$$\log_e B(\theta) = (N_1+N_2)\log_e V e^{\varphi/RT} - \frac{1}{V}\Big[\beta_1 N_1^2 + 2\beta_{12}N_1N_2 + \beta_2 N_2^2\Big] - \ldots,$$

where β_1, β_2 and β_{12} are the usual virial coefficients. Writing suffix *g* and *a* for the gaseous and adsorbed phases respectively and assuming the gas phase to be perfect, it is now easy to prove that:

$$\log_e \frac{x_1}{p_1} = \log_e \frac{V_a}{RT} + \log_e \left\{\frac{h_a(\theta)}{h_g(\theta)}\right\}_1 + \frac{\varphi_1}{RT} - \frac{2}{V_a}\Big[\beta_1' x_1 + \beta_{12}' x_2\Big] - \ldots$$

$$\text{and } \log_e \frac{x_2}{p_2} = \log_e \frac{V_a}{RT} + \log_e \left\{\frac{h_a(\theta)}{h_g(\theta)}\right\}_2 + \frac{\varphi_2}{RT} - \frac{2}{V_a}\Big[\beta_2' x_2 + \beta_{12}' x_1\Big] - \ldots,$$

where x_1 and x_2 are the amounts of *R* and *S* adsorbed per unit area at partial pressures of p_1 and p_2 respectively, and φ_1 and φ_2 are the adsorption potentials of *R* and *S* respectively: V_a is the adsorption volume. The values of $\{h_a(\theta)/h_g(\theta)\}$ can be evaluated as shown in the paper mentioned already and β_1', β_2' and β_{12}' are closely related to the three-dimensional virial coefficients.

These equations are very similar to those for adsorption from a single gas, namely,

$$\log x/p = K(T) - K_1 x - \ldots ,$$

but K_1 is, in the case of mixtures, a function of the composition of the adsorbed phase. For low surface concentrations we obtain the well-known results

$$x_1/p_1 = k_1(T) \qquad x_2/p_2 = k_2(T).$$

By suitable approximations these virial adsorption isotherms can be converted into the Langmuir isotherm for mixtures

$$x_1 = \frac{a_1 b_1 p_1}{1 + a_1 p + a_2 p_2}$$

with detailed expressions for the constants a_1, a_2 and b_1.

The application of the virial adsorption isotherms to careful measurements made over a wide range of experimental conditions so that $\{h_a(\theta)/h_g(\theta)\}$ and β_1' and β_{12}', etc. can be evaluated should enable us to obtain important information concerning the state of molecules in the adsorbed phase.

Defect Lattices and Catalytic Activity

A RECENT X-ray examination of the nickel-aluminium system[1] revealed the existence of the following phase-structures: Ni_3Al, Ni_2Al_3, and $NiAl_3$, in addition to the solid solutions of aluminium in nickel and nickel in aluminium. Ni_3Al is face-centred cubic and has a superlattice in which nickel atoms are at the centres of the cube faces while aluminium is at the cube corners. NiAl is body-centred cubic with aluminium at cube corners and nickel at cube centres. It was found that alloys with the NiAl type of phase structure were progressively more deficient in nickel atoms at cube centres, leaving vacant sites as the aluminium content of the alloy was increased. The absence of one third the number of nickel atoms changes the composition from NiAl to Ni_2Al_3 and produces a debasement from cubic symmetry to trigonal. The δ-phase structure Ni_2Al_3 can best be thought of as a deformed NiAl type. The empty sites in the structure are regularly distributed in planes perpendicular to the trigonal axis.

On treating the alloy Ni_2Al_3 with sodium hydroxide solution, one is able to dissolve out the aluminium. It has been found possible to change the composition of Ni_2Al_3, which corresponds to 59·2 per cent nickel (by wt.), to about 80 per cent nickel and yet *retain* the *trigonal* symmetry of the crystal. If the alloy were in its normal equilibrium state, it would of course consist of two phases, β and α′, which have the NiAl and Ni_3Al types of phase structure.

Further treatment with sodium hydroxide solution ultimately results in the collapse of the δ-structure. An alloy with 95 per cent nickel gave an X-ray spectrum showing the Ni_2Al_3 pattern along with that of two face-centred cubic structures. With less than about 0·5 per cent aluminium, only one face-centred cubic phase remains. It appears that the action of the caustic soda solution is to remove aluminium atoms from the lattice, leaving vacant sites, but that the structure ultimately collapses and tends to form the face-centred cubic structure of nickel.

Apparently, in the process, no intermediate body-centred cubic structure is formed. A further interesting point is that the X-ray spectra are reasonably sharp, indicating that most of the material consists of relatively large particles of the order of 1,000 A.

The research is being continued with a series of binary and ternary alloys of the Ni_2Al_3 (δ) type and also with γ-alloys, which can also be characterized as having a defect lattice formed from a CsCl-type of structure.

The structures described above bear an interesting relationship to the action of these metals as catalysts. Nickel catalysts prepared from nickel aluminium alloys (Raney nickel) are used extensively in industry for hydrogenation purposes. These defect lattices all possess a very large highly unsaturated surface (on account of the lattice defects), and electron transfer processes should be considerably enhanced. It has been demonstrated previously that simple electron transfer processes play an important part in the catalytic decomposition of hydrogen peroxide on metal surfaces[2]. It can also be shown that in hydrogenation, reaction with molecular hydrogen and in the Cannizzaro reaction of aldehydes, which are both strongly catalysed by this nickel catalyst, the essential elementary processes on the surface of the catalyst can be described as electron transfer reactions (that is, oxidation-reduction processes in a chemical sense).

A full account will be published elsewhere.

Similarity and Dissimilarity

CLASSIFICATION is based upon perception of similarity. The following experiment, carried out with the help of about forty observers, in connexion with a course of lectures on scientific method, was designed to get information on the readiness with which similarities are noted.

Various objects were exposed in pairs to those taking part in the experiment. The typed instructions given to each observer were: "Two objects will be placed on the lecture bench and you are asked to compare them. Write down any points of comparison that occur to you, setting them down in the order in which they occur. Any points of comparison *whatever*, relating to the two objects, are asked for. Brief phrases in 'telegraphic English' will suffice." In order that the observers should be unprejudiced, care was taken not to mention either classification, similarity or dissimilarity. A time of 3 minutes was found to be convenient for the comparison of such pairs of objects as an orange and an apple, or an open pen-knife and a pair of scissors.

At the end of the experiments, the answers to three questions were included in each report: "(1) Have you ever taken part in a similar experiment? (2) Have you ever read of similar experiments? (3) By 'compare', did you understand that both similarities and differences were to be included?" The scripts containing answers of 'No' to the first two questions and 'Yes' to the third question were then analysed in terms of the number of similarities and of differences in the comparisons made. The results, with three groups of observers, were as follows:

No. of observers	8	11	9
No. of pairs of objects	3	5	4
No. of points of comparison ..	112	230	131
Similarities	34	53	20
Dissimilarities	78	177	111

It would appear, therefore, that when unprejudiced observers spontaneously make comparisons between pairs of objects, they tend to note many more dissimilarities than similarities.

Those who are accustomed to study scientific method from a philosophical as distinct from a scientific point of view may be inclined to criticize these results, saying that more dissimilarities than similarities are noted in a given time because the objects possess more dissimilarities. But a scientific study of a subject must be based upon observables. How, in terms of observables, are we to know the total number of similarities and dissimilarities possessed by a pair of objects? When attention was directed to many unnoted similarities, they could all be recognized as such by the observers taking part.

In biological experiments variations are invariably found with the individual. It is therefore significant that for no unprejudiced observer was the number of similarities equal to or greater than the number of dissimilarities. Of prejudiced observers, six who tried to include only similarities, gave 95 points of comparison, of which 14 were dissimilarities, in spite of the effort to include similarities only. Two other prejudiced observers, who tried to include dissimilarities only, gave no similarities. The mean numbers of points of comparison per person for each pair of objects were:

Unprejudiced	4 6
Dissimilarities only . ..	4 6
Similarities only	5 3

Although these results are presented here for their relevance to the *scientific* study of scientific method, they would appear to have some bearing also on social problems. Not only do some individuals show great talent for selecting differences in dealings with their fellow men, but also, in international affairs, nations at the present time are stressing a few points of difference instead of their many points of similarity.

I should be grateful to hear of any other experiments bearing on the perception of similarity or the *scientific* study of scientific method.

Karrer's Theory of Coupling

In 1915, Karrer[1] put forward the view that the coupling of aromatic tertiary amines with diazo-compounds to form alkylamino azo-compounds takes place through the preliminary combination of the diazo-compound with the nitrogen of the amino group. The experimental basis for this theory was the reported observation that when either di-butylaniline or di-*iso*amylaniline reacts with diazo-sulphanilic acid, an alkyl group is eliminated with the formation of the corresponding monoalkylamino azobenzene sulphonic acid.

It is unfortunate that Karrer did not specify more exactly which of the di-butylanilines he employed. We have repeated Karrer's experiments with both the dibutylanilines described in the literature, namely, di-*n*-butylaniline and di-*iso*butylaniline. Both are found to couple normally without the loss of a butyl group. This confirms an earlier observation by Reilly and Hickinbottom[2] that di-*n*-butylaniline reacts normally with diazosulphanilic acid. It is also found that diazosulphanilic acid couples with di-*iso*amylaniline without the loss of an alkyl group.

It is concluded that Karrer's observations were at fault and that there is no experimental basis for Karrer's theory of coupling. This conclusion is supported by the observation that methyl *tert*-butylaniline also couples with diazo-compounds without the loss of an alkyl group, although it has been shown earlier that the *tert*-butyl group is only loosely bound to the nitrogen[3].

During the course of this work, it was also found, contrary to Karrer's observations, that the two dibutylanilines and di-*iso*amylaniline react with nitrous acid in aqueous acid solution to form *p*-nitroso compounds.

Enzymatic Removal of Bound Carbohydrate from Normal Horse Serum Pseudoglobulin

By the use of the preparation 'Luizyme' (Luitpoldwerke, Munich, to which I am indebted for a sample) part of the bound carbohydrate can be removed from horse serum pseudoglobulin. The enzyme is active at pH 5 in $M/2$ acetate buffer. Owing to inhibition by the products of digestion, the action comes to an end within four hours at 37°, and it was necessary to submit the protein to successive treatment with fresh lots of enzyme. Ammonium sulphate (40 per cent saturated) was used at every stage as protein precipitant, and repeated reprecipitation was shown not to effect removal of carbohydrate. The slight proteolytic activity of the enzyme preparation under these conditions is quite insufficient to account for the splitting of carbohydrate from the protein.

The effect of successive digestions, shown in the accompanying table, on the amount of bound carbohydrate estimable by the method of Sørensen and Haugaard[1], suggests a specific removal of one part of the galactose-mannose-glucosamine complex. The protein recovered after ten digestions did not differ markedly in its properties from the original protein, either in solubility, in ultra-violet absorption or in its potentiometric titration curve. Ultra-centrifugal sedimentation showed it to be rather heterogeneous, though at least a third of it had an unchanged sedimentation velocity.

No. of successive digestions	Per cent of total estimable carbohydrate remaining (± 3 per cent)
1	80
5	56
5	51
8	50
10	49

Precipitin tests with anti-horse globulin sera showed certain differences—increased flocculation time, decreased precipitability and changed optimum proportions—compared with the original protein. These differences might be due to loss of bound carbohydrate or to slight proteolysis, but they seem small in consideration of the extensive treatment of the protein and the considerable change of carbohydrate content.

These results, repeated on several samples of protein, suggest that the part of the carbohydrate removed may not be important in determining the properties of serum pseudoglobulin.

I am grateful to Prof. J. R. Marrack for the precipitin tests, to Mr. E. R. Holiday for measuring the ultra-violet absorption and to Mr. J. St. L. Philpot for measuring the ultra-centrifugal sedimentation.

Schütz's Law and the Clotting of Blood

IT seems worth while to point out a misunderstanding of Schütz's law, which has been found in works on blood clotting, and which has been accepted in reviews on this subject[1,2].

Fuld[3] (cf. later Tsunoo[4]) first applied Schütz's law to the clotting of blood plasma. Now, the results obtained by Schütz[5] show that the amount of albumin digested in a given time is proportional to the square-root of the amount of enzyme, that is,

$$[P] = \text{const.} \times \sqrt{[E]}. \qquad (1)$$

In Schütz's law the reaction time t does not appear as a variable, and so the law cannot, of course, be used for the characterization of time relations. In blood-clotting, t and $[E]$ are the only measurable quantities, while $[P]$ is constant, and it follows that the original law of Schütz is of no value in these circumstances. To extend the formula, t must be incorporated, based upon experiments, and in this way Arrhenius[6] obtained the equation:

$$[P] = \text{const.} \times \sqrt{[E] \cdot t}\,; \qquad (2)$$

but this is not the law used by Fuld[3]. The rule referred to by Fuld as Schütz's law can be formulated as

$$\frac{1}{t} = \text{const.} \times \sqrt{[E]}, \qquad (3)$$

and on comparing (3) with (1), it appears evident that an incorrect use of $[P]$ and $1/t$ as interchangeable measures of reaction velocity has led to this misunderstanding. Bodansky[7] has recently shown similar confusions to exist in general in enzyme chemistry.

A detailed study on the clotting time of blood is to be published soon.

Cancers of Infancy and Anærobic Glycolysis

CRAMER[1] has directed attention to the fact that the retinoblastoma, which appears almost exclusively in infants, and the chorion-epithelioma arise from tissues that have a type of metabolism resembling that of tumours.

Besides the retinoblastoma, the neuroblastoma and nephroblastoma are also tumours of the first few years of life, and in recent years it has been shown that brain and kidney medulla[2] have a high glycolysis. Thus these tissues also have a metabolism resembling that of embryo and of tumour, and this may have some connexion with the occurrence of these tumours in the early years of life. Whether the nephroblastoma arise from the medulla of kidney is doubtful, but in my opinion these relations are of the utmost importance and should be borne in mind by pathologists and workers who hope to unravel the causative mechanism of cancer.

It is irrational to work on the hypothesis that cancer afflicts cells and tissues of all ages through the same mechanism, when the cancers of infancy may constitute a separate category by virtue of the peculiar metabolic properties of the tissues of their origin.

Dissolving Action of Micro-Organisms on Milk-Wool

IN NATURE of April 9, Prof. Jan Smit and B. Van der Heide gave the results of some work which they have carried out on the action of micro-organisms on milk-wool. This communication was brought to the notice of Messrs. Snia-Viscosa, of Milan, the manufacturers of, and Comm. Ferretti, the inventor of, "Lanital", the trade name given to the so-called casein or milk-wool made by the Ferretti process. In reply, they state that although "Lanital" has been in commercial use for some years, no case of attack of "Lanital" by micro-organisms has come to their notice; on the contrary, it is found that whereas wool is attacked by moths, "Lanital" is not.

Synthesis of α-Tocopherol (Vitamin E)

WE have described[1] the synthesis of a compound, obtained by letting phytyl-bromide react with trimethyl-hydroquinone. We also expressed the opinion that this substance might be the racemic form of α-tocopherol.

In the biological test this compound gave excellent vitamin-*E* activity in doses down to 6 mgm., the smallest tested so far. By means of brom-camphor sulphonic acid, the racemic compound can be split up into the optically active forms. The brom-camphor sulphonate of the synthetic compound shows the same melting point as the corresponding α-tocopherol derivative (48–50°), and mixed together there is no depression. The optical activities are identical: $[\alpha]_D = +30° (\pm 2°)$ in alcohol.

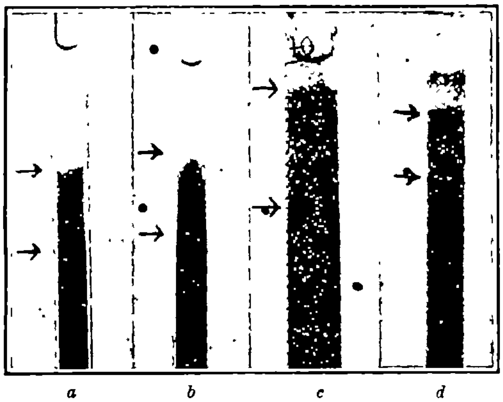
Stratified Blood Sedimentation—Isolation of Immature Red Cells

DURING sedimentation tests, blood often forms a clearly demarcated zone of red cells above the main sedimenting column[1]. Typical appearances are shown in the accompanying photographs.



STRATIFICATION IN BLOOD SEDIMENTATION TESTS IN SECONDARY ANÆMIA OF (*a*) TUBERCULOUS ADENITIS, (*b*) BRONCHOPNEUMONIA, (*c*) AND (*d*) ANÆMIA IN DOG.

Red cells of the upper zone, or of the diffuse upper cloud when the stratification is not clear cut, are all immature. In some cases, the upper zone contains up to 85 per cent of reticulocytes, less than ½ per cent being found in the main sedimenting column. Withdrawal of the upper zone and resedimentation enables the relatively few immature cells carried into the lower column to be separated.

The formation of the upper zone is due to the low aggregation tendency of the red cells comprising it, but these also have lower electrophoretic speeds, usually two thirds to a half that in the lower main column, the same ratio being found in man and dogs, when measured in isotonic sucrose solution buffered at *p*H 7·4. The low electrokinetic potential thus evidenced should favour aggregation, so that the non-aggregation indicates a marked deviation from the normal erythrocyte surface. Here, however, the usually more spherical shape of the upper zone corpuscles must also be considered. Typically the upper zone red cells have the same absolute electrophoretic speeds as leucocytes in the same animal, the surface resemblance being also shown by the low aggregation tendency of leucocytes.

In some cases, the upper zone contains only 2–3 per cent of reticulocytes, and in others no reticulocytes but a few red cells showing punctate basophilia. The identity of the upper zone constituents in these cases was established as immature red cells by (*a*) their electrophoretic speeds, (*b*) their occasional deeper generalized basophil staining than cells in the lower column, and (*c*) their diminished aggregation tendency, which is the cause of the differential flotation.

Sometimes a third uppermost zone forms; it usually contains red cells with electrophoretic speeds generally half the normal value. This third zone is apparently derived by selective flotation of cells from the stratum of immature cells and could sometimes be induced artificially. The electrophoretic speed always increases from top to bottom strata, and also when there are no definite strata but merely an upper cloud. The simple approximately 2 : 3 ratio corresponds to the reticulocyte phase of maturation. In later phases the electrophoretic speed difference is less marked although the diminished aggregation tendency persists.

Stratification was never seen in normal subjects, but was found in 37 of a series of 56 patients, and in splenectomized or desanguinated dogs. Of the human patients exhibiting the phenomenon, 35 showed some degree of secondary anæmia.

Stratification is an indication of bone marrow reaction and is of importance in revealing young cells not identifiable by staining. It occurs in association with normal and increased sedimentation rates as measured to the top of the lower main column. Both when stratification is present and when absent, a new factor, the age of the red cell population, must be considered in relation to sedimentation rates, and indications have been found that young bloods sediment more slowly than old ones, other factors being equal.

Even when stratification does not appear, immature cells are concentrated in the upper limit of the sedimenting column. Centrifugation without sedimentation also causes immature red cells to be concentrated in the upper limit of the centrifuged deposit.

Motor Spirit from Coal

OUR attention has been directed to the article by Messrs. J. L. Strevens and A. C. Cross in NATURE of May 7 on "Motor Spirit from Coal". We have no desire to enter into any controversy on a subject ably and impartially covered, in our view, by the Falmouth Committee, but we cannot help correcting at least two misstatements.

It is stated that "the octane rating of this spirit [produced by hydrogenation] is 70 plus". The hydrogenation process is elastic enough to enable us at Billingham to produce regularly no fewer than four different types of spirit: aviation (87 O.N.), ethyl spirits (81 O.N.), Straight No. 1 spirits (75 O.N.) and commercial grades (68 O.N.). All these petrols are used directly, without admixture with other materials, for their appropriate purposes.

Again, it is stated that "phenols so essential to the nation's needs in times of peace and war can only be obtained from coal distillation processes and the tar industry, and not from hydrogenation or synthesis". When coal is hydrogenated it gives a much greater yield of phenol than when it is carbonized; typical figures per 100 tons of coal treated are: hydrogenation, 0·9 ton; distillation, 0·03–0·04 ton according to temperature of carbonization. In actual fact, during 1937 the production of phenols manufactured on the hydrogenation plant and sold was more than 850 tons. This figure is well below the present capacity of the plant.

J. E. JAMES.
(Secretary.)

Imperial Chemical Industries Limited,
Millbank, London, S.W.1.

IN reply to Mr. James's letter, we have to make the following comments.

In the 1936 report of the Imperial Chemical Industries, Ltd., it was mentioned that plant had been installed for the recovery of two further by-products, phenol and cresol, and in the 1937 report that the phenols production from that plant had amounted to 850 tons.

As it is usually accepted that complete hydrogenation-reduction of phenols present in coal oils and coal derivatives leads to the ultimate production of hydrocarbons, it seems that the commercial hydrogenation of mixtures of coal and coal oils is incomplete and there naturally remains end-products still containing unconverted phenols. Every additional source of phenol production is of great national importance.

Our authority for the statement on octane ratings of 70 plus for the motor spirit produced by hydrogenation was Prof. W. A. Bone and A. N. Himus's most recent treatise on "Coal: its Constitution and Uses" (1936), p. 564, wherein the figure given for the No. 1 straight undoped spirit is 71–73. Aviation spirit was never under consideration in the article because, so far as octane rating is concerned, this is standardized at 87, and every spirit must conform to it, whatever the method adopted to reach this rating.

The modifications to plant that have been necessary at Billingham to permit of the production of straight 75 octane No. 1 spirit were briefly referred to in the Company's annual report for 1937.

The Piltdown Bone Implement

MR. REID MOIR[1] mentions the theory that the bone implement from the Piltdown gravel was made by a rodent mammal, not by man. One of the finest examples of bone gnawed by rodents (presumably porcupines) is a fossil skull of the extinct panda, *Aelureidopus baconi*, which is exhibited in the British Museum (Natural History) not far from the implement. It is therefore easy to compare the work of rodents with that ascribed to man.

Eggs of Stick Insects

JUDGING by a recent correspondence in NATURE[1], a number of readers are interested in rearing the common stick insect (*Carausus*). In any quantitative work on *Carausus*, it is a tedious operation to secure the eggs which are deposited among the debris of the breeding cage where, on account of their 'protective' devices, they may easily escape observation.

One of my students, Miss C. McK. Campbell, has devised a very easy method of securing the eggs, which may be of use to others. She plunges the whole of the floor contents of the breeding cage into a vessel containing water, stirs well, to break the surface film and so thoroughly wet each egg, and then allows the whole to settle. The eggs fall to the bottom, the debris floats. The supernatant material having been poured off the eggs can be carefully dried, counted and stored.

Stability of Intermetallic Compounds in the Molten State

THE atomic nature of solutions of cadmium in molten cadmium chloride (so-called 'pyrosols') was proved by an investigation of the partition coefficient of cadmium between molten cadmium chloride and a molten metal phase, such as bismuth[1].

The solutions of sodium in molten sodium halides (for example, sodium bromide or iodide) are being studied at present on similar lines by investigating the partition of sodium between molten sodium bromide and molten lead at 770° C. in sealed tubes of Supremax glass. These systems also prove not to be colloidal. The partition curves reveal, however, the existence of strong interatomic forces in the metal phase which render a detailed analysis of the curves difficult.

A striking behaviour is observed when molten bismuth is used in the metal phase instead of lead. Bismuth, like lead, is not soluble in molten sodium bromide. However, when alloyed with sodium, considerable quantities of bismuth (up to several per cent) pass into the salt phase. Bismuth and sodium form compounds of considerable stability[2], the maximum in the phase diagram being at 775° C.* Obviously one of these compounds, presumably Na_3Bi, is soluble in the molten salt. A similar phenomenon is observed when a sodium alloy of antimony or tin is used as a liquid metal phase. The maxima in the phase diagrams of these metals with sodium are at 856° C. and 580°. On the other hand, thallium, cadmium and lead do not pass into the salt phase when alloyed with sodium. These metals also form intermetallic compounds with sodium, but the maxima in the phase diagrams are at much lower temperatures (Na-Tl : 305° C., Na-Cd : 385° C., Na-Pb : 405° C.). Obviously these compounds are practically entirely decomposed at the temperature of our experiments, which is 350°–450° higher. The results obtained by the partition coefficient method therefore suggest that compounds of sodium with heavy metals may be stable at temperatures up to about 200° above the melting temperature of the compound, but decompose at higher temperatures.

Illusion of Convergent Beams of Light

IN a recent letter[1] under this title, Dr. A. H. Rosenthal describes an optical illusion produced by the rotating beam from a lighthouse. We studied this phenomenon last year[2], and we think that both perspective and photometry are required for its explanation. Diffusion laws show that the brightness of the beam is great near the opposite horizon; this fact, together with the apparent convergence, gives to the observer a strong impression that the lighthouse is just beneath the horizon.

The Editor of Nature has very kindly let me see the interesting communication from MM. Colange and Le Grand and the paper to which they refer.

The phenomenon is exactly the same as that observed by me, and the paper seems to provide a most plausible explanation for it.

Besides the purely geometrical cause for the increased brightness of the beams towards the opposite horizon, contributing strongly to the illusion of an 'anti-phare', another cause might be the usual density gradient of the haze towards the sea, and therewith an increase of the amount of light scattered back to the observer per unit volume from the beam, towards the opposite horizon.

A Binocular Illusion

Waking under my mosquito net one morning during a visit to India, I was surprised to find that the wall of the net before my eyes appeared to consist, not of a single vertical sheet of netting, but of three or more sheets. On closer examination, I found that these seemed to be arranged like the successive slats of a venetian blind, and supposed this to be a binocular illusion—a variant of that mentioned by Prof. H. H. Dixon[1]—the nth mesh seen by one eye combining successively with the $(n-1)$th, nth, $(n+1)$th . . . mesh fixed by the other eye.

The first minute after waking from sleep, when vigilance and control are weak, is doubtless conducive to the involuntary experience of this type of illusion. For, on returning to Cambridge I asked a group of physicists if they knew of the possibility of such binocular illusions, and the only affirmative reply came from one to whom a patterned bedroom wall-paper had afforded a similar experience (complicated by the activity of a house-fly).

Points from Foregoing Letters

The dependence of heat conductivity of quartz on the size of the crystals has been determined by Prof. W. J. de Haas at very low temperatures (2·5°, 2·9° and 3·3° K.). The heat resistance was found to approach asymptotically a constant value. The author assumes that the resistance is due to scattering of the elastic waves by the surface and by the mosaic structure, and to scattering of the elastic waves by one another.

G. T. Seaborg and D. C. Grahame find that internal conversion of the gamma rays of moderate energy, with a conversion coefficient as high as 15 per cent, occur in the heavier elements. In view of the observation by Kallmann and Kuhn that gamma rays are emitted in the D-D reaction, the authors suggest that gamma rays may be responsible for the rather large number of counts observed in a Geiger-Muller counter operated near a source of fast neutrons, and that it may be unnecessary to assume, as Kikuchi and Aoki have done, that a direct interaction between fast neutrons and electrons takes place.

Commenting on the observation reported by Bernard, identifying the yellow radiation of the night sky and the twilight with the sodium line, Prof. J. Cabannes, Prof. J. Dufay and J. Gauzit refer to findings by previous investigators who had come to the same conclusion, and describe similar work which they themselves had carried out and published simultaneously with Bernard.

Using the method of partition functions, the statistical mechanics of the adsorption of gaseous mixtures is discussed by Dr. F. J. Wilkins with due allowance for the imperfection of the adsorbed layer. Adsorption isotherms for the separate gases are derived.

X-ray examination of nickel-aluminium alloys has shown the existence of three phases, Ni_3Al, Ni_2Al_3, and $NiAl_3$, with distinct structures. Dr. A. Taylor and Dr. J. Weiss find that by treating with sodium hydroxide solution it is possible to remove aluminium atoms from the lattice leaving vacant sites; when only 0·5 Al remains the structure ultimately collapses and tends to form the face-centred cubic structure of nickel. Electron transfer processes are probably considerably enhanced in certain nickel structures with different lattices which possess a very high unsaturated surface, and this may explain the activity of such substances as catalysts in hydrogenation.

Many more dissimilarities than similarities were noted in a series of experiments made by Dr. W. H. George, in which about forty unprejudiced observers spontaneously made comparisons between pairs of objects. Reference is made to the bearing of the results on classification and on social problems.

Dr. W. J. Hickinbottom and E. W. Lambert find that the two known di-butylaniline couple normally with diazosulphanilic acid without loss of a butyl group. Their findings do not agree with those upon which Karrer based his theory of coupling of aromatic tertiary amines.

About half the bound carbohydrate in horse serum pseudoglobulin can be removed, according to A. G. Ogston, by digestion with a special enzyme. The pseudoglobulin so treated shows increased flocculation time and decreased precipitability, but on the whole its properties are not greatly changed considering the considerable change in carbohydrate content.

E. E. Faerber suggests that the cancers of infants, which affect tissues such as the retina, constitute a separate category, by virtue of the peculiar chemical reactions in the tissues affected.

The upper stratum of red corpuscles seen in blood sedimentation tests is stated by J. G. Stephens to be composed of immature cells with surfaces resembling those of leucocytes. Although the upper stratum frequently contains abundant reticulocytes, other immature red cells, not recognizable by staining, are also thus revealed by their differential sedimentation.

Dr. E. Heymann and H. P. Weber use the partition method to test the stability of intermetallic compounds in the molten state (with sodium as one component). Such compounds appear to be stable up to about 200° C. above the melting point, but decompose at higher temperatures.

Research Items

Africa and Melanesia in Transition

PROF. RICHARD THURNWALD, as a result of his recent travels in Melanesia and Africa, has instituted a comparison of conditions among the natives of the two regions in respect of their reactions to contact with Europeans (*Africa*, 11, 2; 1938). The two peoples are similar in their poverty of technical equipment and traditional knowledge, while their political and economic organization is weak. They lack resistance in their contacts with Europeans. They differ owing to the fact that in Africa the peoples of Bantu stock have been in contact for centuries with pastoral peoples occupying the greater part of the territory south of the Sudan, who have passed on to the Bantus elements of their culture and their blood. The Melanesians, on the other hand, have received cultural elements from Asia, China and the Indies. As regards the natives of East Africa, mention must also be made of their contacts with the Arabs, lasting over some centuries and leading to the founding of Zanzibar and the establishment of the cross-bred Swahili people and language. No such preliminary contacts occurred in Melanesia. The Chinese trading centre on Celebes has left no trace in New Guinea. The gap between old and new is therefore much wider in Melanesia than in Africa. When the Europeans came to Africa they had to meet the resistance of the dominant races—Arabs, Swahili, Masai, and the Ful. After some quarrels, these aristocratic herdsmen offered their dependants for the labour required by the Europeans. Hence foreign labourers were not introduced into Africa. The aristocratic rule of Polynesia and Micronesia was mitigated by the fact that all strata of the population were equally agriculturists. Hence the lower classes, imitating the attitude of the higher, refused to labour for the Europeans, and foreign races were imported for the purpose. After surveying the various points of contact—missions, education and administration—it would appear that the chief difference between the two regions lies in the stage of the process of contact which each has attained.

Teeth and Jaws of *Dryopithecus*

THE Yale-Cambridge Expedition to the Siwalik Hills of 1935 under Dr. H. de Terra secured a small but valuable collection of fossil apes' teeth and jaws, which have been made the subject of a study by Dr. W. K. Gregory, Dr. Milo Hellman, and Dr. G. Edward Lewis (Carnegie Institution, Washington, 1937. Pp. 27+8 plates). Comparison has been made with other specimens lent, or represented by casts, from India as well as with those collected by the expedition of 1931–33. The number of new or supposed genera of fossil apes has been increasing with every fresh collection made, and it was hoped that it would be possible by this study to demonstrate synonyms. It was evident that the range of difference in size, form, and detail of molar patterns was great, and that there had been a wide generic radiation of the anthropoids in the region now the Siwaliks. Some progress has now been made in this direction, while evidence has been supplied on the phylogenetic sequence of certain species. Taken as a whole, the Siwalik anthropoids were of a distinctly infra-human grade of evolution, but in particular features, now one now another, they approach and even overlap the outer zone of human variations. For example, the second and third molars of *Brahmapithecus thorpei* in respect of breadth indices even surpass some human teeth. It has been shown that the lower molars of Siwalik anthropoids also exhibit many minor variations of what has been called the *Dryopithecus* pattern. It is important to emphasize (1) that the extinct anthropoid apes ranged over an enormous area in the eastern hemisphere—from Spain to India and China, and from Egypt to South Africa; (2) that the group is exceedingly variable, at least in details of jaw and dentition; (3) that while the Siwalik genus *Ramapithecus* and the South African *Australopithecus* are still simian by definition, they are almost at the human threshold at least in respect of their known anatomical characters. Nor can we find that the peculiar features in the teeth of *Sinanthropus* and later hominids are anything more than specializations of later date than the opposite characters found in the upper Tertiary anthropoids of the Siwaliks.

Blood Groups in China

IN the course of an extended series of anthropological investigations among the peoples, Chinese and aboriginal, of the Province of Szechwan, West China, Prof. W. R. Morse of the West China University College of Medicine, Chengtu, with his colleagues, has recorded a number of observations on the blood groups of the Ch'wan Miao and the Szechwanese (*Man*, May 1938). The Ch'wan Miao are one of a number of Miao tribes, and number about 100,000. The Province of Szechwan is an ancient centre of anthropological significance. The Chinese population is neither autochthonous nor homogeneous. The Chinese did not enter the territory until about 200 B.C., when they first appeared in small number; but the aboriginal tribes already had a highly developed civilization with temples, schools, and irrigation, so far back as 1200 B.C. The Ch'wan Miao have been very considerably permeated by the culture of the Chinese; but they have a distinct unwritten language, which differs considerably from that of the Chinese, as also do their folk-lore, songs and music. They have a peculiar bamboo wind instrument of a composite character, which sounds very much like the Scottish bagpipes. The clothes and hats of the women are often beautifully decorated, while some of the men also wear embroidered clothes, but more commonly dress as do the Chinese. Neolithic stone implements have been found here in considerable numbers. Observations of the blood grouping were made on 205 Ch'wan Miao (157 males, 48 females) and 1,292 Chinese of the Province. As compared with the Szechwanese the Ch'wan are very low in *A* and high in *B*. The figures are as follows:

	O	*A*	*B*	*A B*	Total
Ch'wan Miao	74	23	80	28	205
per cent	36·1	11·2	39·0	13·7	
Szechwanese	487	375	289	141	1·292
per cent	37·7	29·0	22·4	10·9	

The blood grouping was done chiefly by Mr. S. C. H. Yang, assisted in part by Dr. Y. T. Beh.

Structure of Fœtal Asiatic Elephant

Prof. W. C. Osman Hill illustrates and describes the external features of a mid-term fœtus of Asiatic elephant which has been studied radiographically (*Ceylon J. Sci.* (B), 21, Pt. 1, 31). Comparison of the fœtal mandible with later stages of development suggests that the growth of this bone indicates repetition of phylogenetic history as Eales found in the African elephant. The state of ossification of the limbs is relatively less advanced than in other ungulates, and in this respect is more in keeping with the development of the human skeleton. On the other hand, the heart (described in the following paper) lags in development, and its condition in the advanced fœtus is comparable to that in a human embryo of the fifth week of intra-uterine life. Even in adult life the heart retains a number of primitive features concerned with form and structure, such as the great transverse breadth relative to other dimensions, the relatively large size and globular form of the ventricles, the apical bifurcation, certain arrangements in the interior of the right atrium, the absence or incipient nature of the atrial appendages, and the poor differentiation of the papillary muscles. Various other points of anatomical interest are referred to in this account.

Starlings colonizing Canada

The common starling (*Sturnus vulgaris*) was first recorded in the Toronto region in 1920; about two years later the second record was made. That was the beginning of a settlement, which slowly increased in numbers and in extent during the next three years to 1925, in which year a speeding up in the progress of the movement was noted. The second five-year period, 1925–30, was a boom period when the possible nesting sites which had been tenantless in 1920 were taken over by starlings, with the exception of the noisy downtown business blocks, where only a few birds had taken occupation (*Canadian Field Naturalist*, 51, 124; 1937). The authors, L. L. Snyder and J. M. Spiers, state that the numbers of starlings in the area reached "super-saturation" in 1928, and afterwards in 1932 and 1935, suggesting a population cycle over approximately a three-year period. In the course of seasonal fluctuations, March shows a marked rise in numbers of birds. This is caused by the influx of migrants, as ringing methods have helped to establish; but shortly thereafter the emigrants which are to breed in the far north set out, and Toronto's starling population falls to the low winter-level. In May incubation reduces the numbers to half the winter population. July sees the appearance of family flocks which combine for roosting purposes into the enormous flocks of September. The month of smallest numbers is November, owing to a previous southward migration, but a fairly constant number remains in Toronto over winter.

British Fleas and their Hosts

Gordon B. Thompson has recently given an analysis of the hosts of the thirty-four species of fleas that are known to occur on British mammalia (*Entomol. Mon. Mag.*, May 1938). The author stresses the necessity for workers who publish records of these parasites to be especially careful to give full data as to their hosts, which is more important than a record of a locality alone. He divides the mammalia-fleas into four groups: (1) fleas with marked host specificity; (2) those associated with man and domestic animals; (3) bat fleas; and (4) fleas parasitic on small mammals. It may be mentioned that the plague flea, *Xenopsylla cheopis*, except for five records in 1911 off *Rattus norvegicus* captured at Guy's Hospital, has only been taken off rats in seaport towns. The flea *Orchopeas wickhami* is not truly British, since it came into this country with the introduction of the grey squirrel. Of the bat fleas, most of them are known from more than a single species of host, and the same remark applies to those fleas which are parasites of the smaller mammalia.

Rose Literature

A copious summary of "Writings on the Rose" has recently appeared from the pen of Mr. H. R. Darlington (*J. Roy. Hort. Soc.*, 63, Pts. 3 and 4, March and April 1938). The account traces the documented history of the rose from the decline of the Roman empire. Monastic writings provided the main sources of early information, but the accounts were often derived from classical sources, and showed little actual observation. Medical men began to take an interest in the medicinal value of the rose, and from the middle of the sixteenth century the medical aspects predominate in the literature. By 1650, the garden value of the rose gradually superseded its medicinal virtues, and the century 1750–1850 was a period of intensive writings by nurserymen and botanists. A great increase in the popularity of roses followed a little later, greatly stimulated by that "trinity of ecclesiastical writers, Dean Hole, Foster-Melliar and Pemberton", and this growing appreciation by a wider public has culminated in the great wealth of rose literature at the present time.

Storage of South African Fruit

According to the report of the Low Temperature Research Laboratory, Cape Town, for the year ending June 1938, the new laboratories and offices adjacent to the cold stores at Cape Town are now in use, and the cold stores at East London and Port Elizabeth are completed or nearing completion. Navel oranges and other citrus fruits are shipped from East London, apples, pears, grapes, plums and peaches from Cape Town and Port Elizabeth. Both refrigerated and non-refrigerated but ventilated cars have been used for transport by rail from the orchards to the cold store at the shipping port. The slight superiority of grapes transported in refrigerated cars seems insufficient to justify the extra cost. The investigations carried out in the laboratory have led to the conclusion that the defects in stored plums and the woolliness in peaches are due to too low temperature of stowage. The use of impermeable wrappers for grapes has resulted in an improvement in their quality, but the wrappers encourage mould, against which iodine has proved the best preventive. The rate of ripening of apples in store may be retarded by spraying them with a weak solution of maleic acid in water or in an alcoholic solution of benzyl cinnamate.

A Fungus Disease of the Viola

A fungus which causes a disease of the viola has been studied by Miss Marie E. Campbell (*Ann. App. Biol.*, 25, No. 1, 115–121, Feb. 1938). The organism is *Ramularia deflectens*, and it produces dark-coloured lesions upon the leaves of infected plants in early spring. Sclerotia-like bodies, which are really undeveloped pycnidia, are found below the epidermis of leaves attacked by the fungus, and mature pycnidia with pycniospores have appeared in culture. Pathogenicity of *R. deflectens* has been established by infection experiments, but the disease is apparently not serious. The host plant appears to overcome the disease during summer, and no practical measures of control seem to be necessary.

Land-locked Fjords in Norway

In a short paper in *Skrefter av Det Norske Videnskaps-Akademi i Oslo, I Mat.-Naturv. Kl.*, No. 7, 1937, Dr. K. M. Strom describes and discusses the peculiarities of Saltfjord and Skjerstadfjord near Bodo in northern Norway. The former is a deep-water basin communicating freely with coastal waters, but the latter communicates with Saltfjord only by three narrow sounds. One is dry at low water, one has a depth of 11 metres and the third has a depth of 26 metres. Skjerstadfjord itself has a maximum depth of 523 metres and has several tributary fjords opening into it. Of these, Valnesfjordvatn has a communicating channel with a depth of only 1·5 metres at low water, and Overvatn opens by a 3-metre channel. Overvatn has a maximum depth of 346 metres and is notable for its greatest depths occurring when the fjord is narrowest, which suggests a striking example of the power of glacial erosion to scoop a deep channel where the ice stream is narrowed. Overvatn, in particular, shows some interesting hydrographical features. The uppermost twelve metres are practically fresh. Below that there is increasing salinity to 21·65 and 22·95 per mille at the bottom. Below 90 metres oxygen is absent, but sulphuretted hydrogen content is low. There is probably no complete renewal of bottom waters; but a partial renewal appears to occur from time to time. Bottom waters with a temperature of 5·33° C. seem to represent cooling during winter and spring by convection currents from the surface.

Evaporation over Catchment Areas

This is the title of a paper by D. Lloyd, read before the Royal Meteorological Society on April 27, 1938. In it a statistical analysis is made of the general annual rainfall over eight British drainage areas, and the annual total loss over each of these areas (obtained by subtracting the run-off from the general rainfall) in relation to various causes of variation of the loss such as fluctuations in the annual sunshine and temperature and differences of percolation associated with different geological formations. Another factor considered is the general rainfall itself, which provides the opportunity for evaporation. The statistical method adopted is that of carrying out separate multiple correlation analyses for different areas and this is held to be more rigorous than the alternative of analysing all samples combined, which last would involve the assumption that the various functions in the regressions are constant for different areas. It was found that the partial regressions of loss on rainfall, temperature and sunshine are probably the same over several of the different areas, and that the loss for a given rainfall temperature and duration of sunshine is the same in all impermeable areas, to which loss must be added the loss during percolation to arrive at the total that may be experienced in any area. A table is given which shows the magnitude of the constants in the different regressions; for example, in the relationship between loss and temperature the variation of loss is given as 1·1 in. for each degree Fahrenheit departure of average temperature from 48° F., for the range 40–52° F., with average speed of the wind, while the annual loss increases by 0·6 in. for each hundred hours of sunshine above a yearly total of 1,450 hours in about latitude 52° N.

K-Electron Capture and Isomerism in Radio-Silver

A study of the radioactivity of the nucleus ^{106}Ag obtained by fast neutron bombardment of silver has enabled M. L. Pool and E. C. Campbell (*Phys. Rev.*, **53**, 272; 1938) to construct a tentative energy-level diagram for the nucleus. The two isomeric nuclei have periods of 24·5 min. and 8·2 days. The 8·2-day period is supposed to belong to the ground state of the ^{106}Ag nucleus. It can decay by *K*-electron capture, or by positron emission to ^{106}Pd or by electron emission to ^{106}Cd. The relative probabilities of these processes are 640, 1, 40. γ-Rays are associated with the first two, arising from excited levels of ^{106}Pd. The 24·5 min. period is supposed to arise in a metastable level of ^{106}Ag. It goes by a positron emission to ^{106}Pd. In order to give the metastable state a sufficiently long lifetime with respect to γ-emission, theory requires a large difference of angular momentum between the states, and in the present case the 24·5 min. state probably has nuclear spin zero and the ground state a spin greater than 5. Alternative explanations of the experimental facts, involving a nucleus ^{105}Ag instead of an isomer, are discussed and shown to be unlikely.

The South Equatorial Current of Jupiter

Mr. A. Stanley Williams has shown that there had been a continual decrease in the velocity of Jupiter's south equatorial current between 1880 and 1910, and that this decrease had probably continued until 1926 (*Mon. Not. Roy. Astro. Soc.*, **96**, 5, March, 1936). On this latter point, however, there was some doubt, as there was a scarcity of conspicuous spots on or about the south equatorial belt, and this region of the equatorial current was generally quiescent. The recent memoir of the Jupiter Section of the British Astronomical Association, February 1937, shows that the decrease in velocity has been a practically continuous one, extending from 1880 to 1931. Mr. Williams has recently continued the discussion of the subject, and points out that between the years just mentioned the decrease in velocity amounts to as much as 40 km./hr. (*Mon. Not. Roy. Astro. Soc.*, **98**, 5, March, 1938). A mean curve affords no indication of periodicity, and a curious feature is the pause and slight increase in velocity in 1900, for which it is difficult to offer any explanation. This south equatorial current is about 275,000 miles long and 4,500 miles broad, its depth being unknown. Mr. Williams assumes the latter to be 10 miles—probably an underestimate—and considers that its average density is about that of our own atmosphere. The question arises: What can be responsible for the decrease in velocity of this enormous current? The great change of energy which is necessary seems quite independent of any solar action, and it probably arises in the planet itself. Observations fail to disclose any connexion with the 11-year sunspot period or with the period of the planet's revolution around the sun. It seems fairly obvious that disturbances involving considerable energy changes are taking place on the planet Jupiter.

Fuel Research Station

Annual Visitation

MORE than three hundred representatives of science and technology visited the Fuel Research Station at Greenwich on May 31. The chairman of the Fuel Research Board, Sir Harold Hartley, was unfortunately unable to be present, and the visitors were received by Dr. F. S. Sinnatt, the director of fuel research. Nearly two hundred and fifty representatives of the Institution of Gas Engineers visited the Station on June 1.

The Fuel Research Station is the headquarters of the fuel research organization of the Department of Scientific and Industrial Research, and is equipped not only with laboratories but also with large-scale plant. In all processes involving heat treatment of coal, the rate of heating has considerable influence, consequently the scale effect is of importance. The aim of the Station is to obtain results that can be directly translated into practice by industry, and this involves the use of plant of a size comparable with that used in industry.

Coal is a variable and complex substance, and the first requisite for its scientific utilization is a knowledge of the properties of the various seams. These are being studied in nine laboratories situated in the principal coal fields. The normal method of examination consists in obtaining a pillar of coal from the coal face, and this is transported to the laboratory, where it is examined in detail. Variations that occur throughout the thickness of the seam are thus ascertained. A section of such a pillar was shown, with an X-ray photograph of a slice cut from the same pillar. This shows the banded structure of the coal, and the distribution of the inorganic matter in the various bands. A number of specimens illustrated the great variations to be found in coal and its associated impurities. When a sufficient number of sections has been examined, it becomes possible to form a picture of the seam over the whole coal field and to predict with some certainty the characteristics of the seam in areas not yet worked. Examples were shown of 'Iso-vol' maps from two different coal fields, showing the volatile content of a seam as it varies from point to point. The areas are clearly indicated from which coal specially suitable, for example, for coke making, gas making, or steam raising, can be obtained.

Modern methods of utilizing coal have increased the importance of a knowledge of the inorganic constituents present, and methods for the examination and analysis of coal and its associated impurities are continually being studied and improved. When coal is burned a certain amount of 'ash' remains, and this is easily determined, but does not necessarily represent in amount the inorganic matter originally present. An exhibit illustrated the changes that take place during ignition, the method of determining the amount of inorganic matter in the original coal, and the actual composition of the coal substance itself.

Various examples of the more common minerals concerned were exhibited. A list of the less common constituents that have been met with was on view, together with specimens of coal containing barytes and galena. Micro-analytical methods for determining the amounts of some of these rarer constituents were shown. Both the normal methods of analysis and modifications for special cases were on view.

One of the difficulties in the examination of coal is the preparation of a fair sample. In the first place, the gross sample taken must be truly representative of the bulk consignment. In the second place, this sample must be reduced to the small sample of finely ground coal which is required in the laboratory, without losing its representative character. New facilities for the rapid and convenient reduction of gross samples have recently been provided.

An investigation of general interest concerns the burning of coal in the open domestic grate. The experiments are being carried out in two specially built rooms of gas-tight construction, so that the air can only enter by one path where it can be precisely measured. The radiation from the fire and the smoke produced are recorded. The results show that the quality of the coal, the size of the coal, the relative amounts of air passing through the fire and entering the flue by passing over the fire, the brickwork surrounding the fire, and the design of the grate all have a significant influence on the amount of smoke emitted.

Two vehicles—a one-ton and a five-ton lorry—were shown, which have been converted to run on producer gas from solid fuels. The first is fitted with a producer made by a British firm and has been used for comparing the efficiencies of different types of fuel—charcoal, cokes of various kinds, and anthracite. The second is fitted with a producer designed at the Fuel Research Station to study the principles involved in the design, with the view of making a more flexible producer. It is giving promising results.

The synthesis of hydrocarbons from carbon monoxide and hydrogen is being studied in several plants, including one producing about 5 litres of liquid hydrocarbons a day. The primary products consist of motor spirit, diesel oil and waxes of high melting point, together with heavy hydrocarbon gases. Lubricating oils, esters and soaps have been prepared from the primary products.

One of the water-gas plants at the Station has been modified so that coal can be used instead of coke. Non-caking coals, either high or low in volatile matter, can be used. This forms one means for the total gasification of coal. Experiments are in progress on raising the calorific value of the water gas, by treating a portion with a catalyst so as to produce hydrocarbon gases. Another modification enables a gas to be made with a higher proportion of hydrogen, and so more suitable for the synthesis process.

Other plant on view included the chamber ovens being used for experiments on the carbonization of blends of coal; the hydrogenation plant, used for studying the suitability of different coals and the action of catalysts; the coal cleaning plant; the plant for boiler firing by pulverized fuel; and the marine boiler for examining bunker coals.

A striking demonstration showed the 'dust proofing' effect of a small quantity of oil when sprayed over coal.

Royal Observatory, Greenwich

Annual Visitation

THE annual report of the Astronomer Royal to the Board of Visitors was presented at the annual visitation of the Royal Observatory, Greenwich, on June 4. The following abstract gives briefly the chief points of the report, which specifies in detail the various activities of the Observatory during the year ending April 30, 1938.

Reversible Transit Circle. The new instrument has been subjected to a very detailed investigation before being put into routine use on a definite programme. The causes of certain discordances, which had been revealed by tests, have been tracked down in the micrometer system and reduced to a negligible amount by minor alterations and critical readjustment. The determination of the division errors of the circle (to be carried eventually to each 5′ division) has been continued. Altogether much useful information is being accumulated on possible sources of systematic error in meridian observations.

Work with the *Airy Transit Circle* has completed during the year an observing programme commenced in 1931 and containing all stars down to mag. 7·5 in the Draper Catalogue between declination 0° and +24°, as well as the stars in Boss's Preliminary General Catalogue between +64° and the pole. Out of about 7,000 stars, more than 6,000 have been observed six or more times.

The departure of the position of the moon from the position given by pure dynamical theory continues to increase; there is no indication of any sudden change in the earth's rate of rotation.

Cookson Zenith Telescope. A determination of the constant of nutation derived from the Greenwich observations made with this telescope from 1911 to 1936 gives 9·217″ ± 0·004″. This value, in conjunction with Oort's value of the constant of precession, gives a ratio of 1 : 81·59 for the mass of the moon to that of the earth. The discussion of the observation of the minor planet Eros, made at the 1931 opposition, should lead to a very precise determination of the mass of the moon and should provide a valuable check on the constant of nutation.

During the year, 271 plates were taken for the latitude variation programme.

28-inch Refractor. The comparison image micrometer, which recently replaced the ordinary bifilar micrometer of this refractor for double star measures, has proved very satisfactory, especially for stars with separation less than 1″. An interferometer has been constructed in the Observatory workshop and is intended for bright binaries that are too close for the comparison-image micrometer.

Thompson 26-inch Refractor. 1,151 plates for the determination of stellar parallax and 105 plates for proper motion determinations were secured. Another 29 parallaxes have been completed.

Yapp 36-inch Reflector. For colour temperature work, 215 comparisons of 79 stars with standard stars have been secured with the slitless spectrograph. Observations on γ Cassiopeiæ, which shows colour temperature variations, are being continued. The Hilger slit spectrograph was mounted in position and tested over a period of nearly two months.

Observations of Eros. A large amount of work has been done at Greenwich on plates taken at various observatories during 1931. The number of positions of the planet to be computed from measures made at Greenwich is more than 1,300.

Astrographic Equatorial. The star field of the total solar eclipse of October 1, 1940 (visible in the southern hemisphere) and two near-by comparison fields have been taken to decide upon the suitability for the observation of the Einstein displacement at this eclipse.

Photoheliograph. The sun was photographed at Greenwich on 284 days. The 1937 daily series assembled from the Greenwich, Cape and Kodaikanal photographs is complete except for one day. The sun's activity in its 11-year cycle, as measured by the frequency of sunspots, is passing through its maximum phase—the highest since 1870. Three spot groups of exceptionally large area (3000 millionths of the sun's hemisphere) occurred during the year.

Spectrohelioscope. Observations of bright chromospheric eruptions on the sun, of which the association with sudden radio fade-outs seems now to be definitely established, continue to be one of the special objects for investigation. The highest radial velocity of a dark hydrogen marking observed during the year was 325 km./sec. outwards from the sun.

Eclipse Expedition, 1940. The Admiralty has authorized the sending of an expedition to South Africa for eclipse observations. It is proposed to study the change from line absorption to emission near the sun's limb by means of a slit spectrograph guided on the moon's limb. It is also planned to study the Einstein displacement with an equatorial camera designed to shift very rapidly from the eclipse field to a check field and back several times during totality.

Time Service and Chronometers. Astronomical determinations of time were made on 109 nights with the small reversible transit. A system of intercomparison of the five free pendulum clocks at Greenwich (and in addition the one at the National Physical Laboratory) has provided a 'mean clock' as datum for prediction of clock error. An increase in accuracy of the time signals disseminated from Greenwich has resulted from this procedure. The rhythmic radio time-signals transmitted at Rugby, the hourly time signals to the G.P.O. and the six dots to the B.B.C. sent every quarter hour have been maintained. The hourly signals to the G.P.O. have been used for the automatic correction of the Talking Clock, which has proved a remarkable success.

It is hoped that the quartz crystal oscillator clock, which is being made at the National Physical Laboratory, will shortly be installed at the Observatory.

The performance of the Westminster clock, which is not corrected by any signals from the Observatory, shows that the error of the signal to Greenwich did not exceed $0{\cdot}2^{s}$ on 131 days; on 18 days the error was greater than $1{\cdot}0^{s}$.

There has been a considerable increase in the amount of testing to be done at the Observatory of Admiralty chronometers and watches; additional chronometer watches will shortly be delivered for testing and purchase. The Observatory now has its own adjusting and repair shop with a small technical staff. The equipment includes an automatic watch rate recorder, by means of which a watch may be tested in all positions and its rate read off in a few seconds.

The Nautical Almanac. During the year, the *Nautical Almanac* for 1938 and that for 1939 have been published. The new *Air Almanac* has been published over an experimental period; from the experience gained, it will, from next January, appear in a completely new form in which the essential data required by the airman can be obtained with much greater ease. Because of the consequent increase in bulk, the *Air Almanac* for 1939 will be issued quarterly. Besides the work on these almanacs, considerable preliminary work and calculation have also been done on other publications to be issued shortly from the Office. The occultation supplement—"The Prediction and Reduction of Occultations"—was published last August and includes a complete description of the occultation machine and the new method of reduction in use at the Office. The extensive occultation predictions for 1940 have been completed.

Magnetic Observations. The mean values of the magnetic elements at Abinger for 1937 are:

Declination, West .	11° 10·4′
Horizontal intensity	0·18522
Vertical intensity .	0·43031
Inclination	66° 42·7′

During the year there were 25 magnetic disturbances reaching storm intensity, of which 3 disturbances were classified as "great storms". A La Cour magnetograph has been installed, and its value was notably illustrated by recording the extreme ranges of *D*, *H* and *V* during the exceptionally violent storm of April 16. The electrification of the railway line through Holmwood to Portsmouth has given rise to grave concern owing to the very marked disturbances of the traces during experimental running of trains. "If," the report adds, "disturbances of the same magnitude prove to be normal, when the regular service is in operation, it will be a matter for serious consideration whether the further continuance of magnetic work at Abinger is justifiable."

Meteorological Observations. For the twelve months ending April 30, 1938, the mean temperature was 51·0° F., which is 1·5° higher than the average of seventy-five years 1841–1915. The month of March was the warmest March ever recorded at Greenwich, being 7·1° above the average. The total rainfall for the twelve months was 19·50 inches, which is 4·74 inches less than the average. Regular records for measurement of the amount of solid matter polluting the air have been continued as well as the measurement of the gaseous pollution of the air by sulphur dioxide. At one time, during the period November 25–28, the amount of solid matter reached 4·4 milligrams per cubic metre, that is, about 7 lb. in the volume of air contained in a cube with one hundred yards edge.

In his concluding remarks, the Astronomer Royal referred to the long series of observations made with the Airy Transit Circle—the fundamental instrument of the Royal Observatory for more than eighty-seven years. More star transits have been obtained with this instrument than with any other meridian instrument. The Prime Meridian Conference which met at Washington in 1884 recommended the adoption of the meridian passing through the centre of this instrument as the initial meridian for longitude. Even if no further observations are made with the Airy Transit Circle, it will be retained in its present position because of its historical interest.

Staff changes include the resignation of Dr. R. v. d. R. Woolley to take up the appointments of chief assistant at the University Observatory, Cambridge, and John Couch Adams astronomer in the University of Cambridge; the resignation of Mr. W. M. H. Greaves to take up the appointments of Astronomer Royal for Scotland and professor of astronomy in the University of Edinburgh; and the retirement of Mr. C. R. Davidson after more than forty-one years of service at the Observatory. Dr. Woolley has been succeeded by Dr. R. d'E. Atkinson and Mr. Davidson by Dr. A. Hunter. Miss F. M. McBain has been appointed assistant and Mr. W. E. Candler temporary assistant at the Nautical Almanac Office.

Tides of the British Seas*

WHILE the tides generated by the sun and moon in an ocean covering the whole earth uniformly would be relatively simple in form, the actual tides are very much complicated by the distribution of the continental land masses and the irregular coast-lines.

The tides of the British seas are largely derived from the tides generated in the Atlantic Ocean. As the tidal wave enters a shallower channel like the English Channel its speed is reduced and its range increased. Consequently in the seas about the British Isles there is a larger range of tide than there is in mid-Atlantic.

The earth's rotation has a considerable influence upon the form of the tidal wave. A wave running up a straight non-rotating channel with parallel sides and uniform depth would have its crests straight across the channel and of uniform height. If, however, the channel is made to rotate, the wave crests, while still straight across the channel, are no longer of uniform height, but are higher on one bank than on the other. Similarly the troughs are deeper on one bank than on the other. When the direction of propagation of the wave is reversed, the phenomenon is reversed, the higher end of each crest being now on the opposite bank. This is roughly exemplified in the English Channel, where the tidal ranges are higher on the French side than those on the English side; and in the St. George's Channel, where the tidal ranges are higher on the Welsh coast than on the Irish coast.

---

* Substance of a lecture by Prof G. R. Goldsborough, F.R.S., to the Newcastle-on-Tyne Astronomical Society, delivered on March 3.

The phenomenon becomes still more interesting when, in the rotating channel, there are two sets of waves proceeding in opposite directions. The effect of uniting the two waves which will have the higher part of their crests on opposite shores is to produce a set of amphidromic points. These are points at which there is no tidal rise and fall of the water level. The points are (under uniform conditions) placed at equal distances down the centre line of the channel. Leading from each amphidromic point is a tidal crest which sweeps round the amphidromic point rather like the hand of a clock (though not necessarily straight) in the period of the tidal oscillation. The channel is thus divided up into separate, independent and similar systems. The tidal range increases as we pass from the amphidromic point outwards along the tidal crest.

The main amphidromic point in the North Sea is over the Dogger Bank, and the tidal crest sweeps down the English coast from north to south and then up the Belgian coast from south to north. A modification is made by the existence of a smaller system of the same kind in the Flemish Bight.

Similar phenomena are found in the English Channel though the amphidromic point is in Wiltshire; and in St. George's Channel where the amphidromic point is in Wexford.

Referring to the effect of wind in altering the mean water level, both theory and observation show that the wind blowing steadily along the surface of the open sea causes a surface drift of the water in a direction inclined at 45° to the right of the wind in the northern hemisphere and a general drift at 90° to the right of the wind direction. In the southern hemisphere the corresponding effects are 45° and 90° to the left of the wind direction. The combination of a strong north-west wind with the perigean tides affords an explanation of the recent flooding of the East Anglian coasts.

Child Nutrition

A NORTHUMBERLAND and Durham Conference on Child Nutrition, organized by the Children's Minimum Council, was held in Newcastle-on-Tyne on May 14. Prof. V. H. Mottram, professor of physiology in King's College of Household and Social Science, University of London, who was one of the principal speakers, posed five questions to which the scientific nutrition expert should be able to give unequivocal answers: namely,

(1) What is meant by an adequate diet?

(2) What is the minimal cost of such a diet?

(3) Is the cheapest adequate diet either dietetically or psychologically possible?

(4) Even if this diet of minimal cost were practicable, could everyone afford it?

(5) Is there indisputable evidence that many children are not able to get adequate nourishment?

In his answer to the first question, Prof. Mottram covered dietetic ground familiar to most readers of NATURE. He stressed in particular the value of milk and fruit as sources of the 'protective' factors of diet. The cheapest diet containing all the necessary constituents in adequate amounts and proper proportions consists of cheese, coarse brown bread and raw cabbage. This would entail no cooking and very little preparation, but would be neither easy to eat nor very digestible. One must consider not only the theoretical value of a diet as purchased but also its 'availability', satiety value and psychological effect. Hunger may be the best sauce, but monotony drives appetite away.

Even so, this primitive and unappetizing pabulum (one dare not dignify it with the title of diet) would cost at least 4/9 per 'man' per week, a sum beyond the purse of more than a tenth of the population of Britain. That is, from purely *theoretical* considerations many people are markedly underfed, while many more—about two fifths to one half—must have dietaries lacking in some of the so-called protective foods. There is no difficulty about the supply of sufficient energy-giving foodstuffs. Calories are cheap—a thousand for a penny—but vitamin-containing foods are relatively expensive.

Is there, however, *actual* evidence of under-nutrition? Nutrition has been given a wider connotation in medical literature than in common speech, which from the point of view of the man-in-the-street is a pity as undefined terms or terms used to cover various meanings lead, and in this instance have led, to bitter wrangling. Using the common meaning of the word, evidence can be produced that malnutrition is too common to be neglected if we wish for a fit nation now or in the immediate future. For example, some 25 per cent of the children in or around London suffer from a lack of a fat-soluble vitamin derived from milk, butter, carrots, etc. This is shown by defective vision in twilight. Even university students, because of the absence of citrous fruit and/or fresh meat in their diet, have been known to show the signs of latent scurvy or even actual scorbutic gums. Lady Mellanby has demonstrated that bad teeth in children were to a great extent due to a low intake of the vitamin D complex found in summer milk and butter.

To some extent, these defects are being overcome by the provision of school meals and milk in schools, and by the provision of cheap or free milk to necessitous nursing mothers and their infants. There is, however, no service to cover the gap between the infant welfare period and the school age. During these three years, irreparable damage may be done. "The schools", said Prof. Mottram, "start with damaged goods". The process of repair is more costly than proper building and, as Lady Mellanby has proved for teeth, 'repair' generally means covering up shoddy material and jerry building with layers of good material. No matter how soundly this later building may be done, the whole structure is rotten at the core.

Miss Rathbone, M.P. for the Northern Universities, urged that immediate action should be taken to remedy this state of affairs, and dealt with the various reasons why schemes at present in operation are only partially effective.

D. B.

Science News a Century Ago

An Unsuccessful Induction Experiment

On June 5, 1838, Faraday made one of his unsuccessful experiments. He experimented, as he tells us in his Diary, "with the view of finding some action on insulating dielectrics analogous to the currents by induction produced in conducting bodies". The arrangement of his apparatus is not without interest, for it is very reminiscent of that used in the famous experiment of August 29, 1831, when he made the discovery of electro-magnetic induction. He had "a ring of iron in form of a cylinder" of two inches external diameter, upon which was wound "80 feet of silked copper wire". The ends of this coil were connected to "a voltaic battery of 10 prs. of 4 inch plates, Wollaston's double coppers, well excited", which was to supply the inducing current.

Little cylindrical cores of shellac and sulphur, with disks of tinfoil pasted to the ends as contacts, were placed within the iron ring, and connected by wires to a galvanometer at some distance. The wires connecting the inducing coil to the battery were then alternately connected and disconnected. At first there seemed to be a deflection of the galvanometer, but it was found to be spurious, and traced to direct magnetic action of the iron ring on the galvanometer needle. After a number of trials, no inductive effect of any kind could be detected with any of the dielectric cores, and Faraday's concluding entry for the day was: "So I cannot thus find any action on insulating bodies analogous to those which occur in conducting bodies: no transverse induction."

The Ashmolean Society

At a meeting of the Ashmolean Society, Oxford, on June 11, 1838, one of the papers read was by Mr. P. Duncan, of New College, who gave some notes on the Columbidæ. These birds, he said, arranged by Cuvier under the order Gallinæ, may be considered as a link between the Gallinaceous and Passerine birds. Only one genus of them has been recognized, which is divided into three sub-genera, according to the relative strength of the bill and proportions of the feet.

There are upwards of 100 species—15 of the Gallinaceous pigeons, 86 of the ordinary and 10 of the Vinago. None of the division Vinago have been found in Europe, North Asia or either of the Americas. The pigeons with the slender bills are not found in Europe, where the most prevalent variety are the common pigeons with moderate bills. The Gallinaceous, distinguished by their short and robust bills, are found in Africa, the islands of the Indian Archipelago and the South Sea and in New Holland. It is to the pigeon that the multiplication of the nutmeg-tree is referred, as they do not digest the seeds of certain fruits. The Nicobar pigeon is distinguished for its brilliant plumage; it runs along the ground and builds its nest like a partridge; it inhabits Sumatra. Of the ordinary pigeons the ring pigeon is the largest and is migratory; they prefer larch to beech or oak woods. The stock pigeon has an affinity to the former kind but they fly in larger flocks and emigrate about October. The author of this paper, Philip Bury Duncan (1772–1863), was keeper of the Ashmolean Museum from 1826 until 1855.

St. John Long's Liniment

At a meeting of the Medico-Botanical Society on June 13, 1838, reported in the *Lancet* of June 30, Dr. Macreight described the composition of the liniment used by the notorious quack St. John Long, the secret of which was sold for £10,000. Dr. Macreight and Mr. Fownes found on analysis of the liniment that it consisted of oil of turpentine and acetic acid held in suspension by yolk of egg. Dr. Macreight said that he had employed the liniment pretty extensively during the last month and found the results consequent on its application exactly the same as from Long's, the effects being what might be naturally expected from any moderate stimulus applied to the skin with dextrous manipulations. Dr. Macreight attributed the successful results obtained by St. John Long partly to legerdemain and partly to the principle that when a substance does not act as a corrodant the surface will ultimately become accustomed to it.

Dinner to Sir John Herschel

On May 17, 1838, Sir John Herschel arrived in England after his four years sojourn at the Cape of Good Hope, and on June 15 he was entertained to dinner in London. The Duke of Sussex presided, and among the four hundred persons present were a large number of noblemen and eminent men of science. In proposing Sir John's health the Duke said: "Prompted by filial duty, and wishing to establish in perpetuity the fame and character of his father—an inheritance which no revolution but nature itself can destroy—he lent himself to what he thought his duty—abandoned his country and his countrymen, left friends behind, took friends with him. He did all this, I say, for the purpose of establishing his father's fame, and recording to posterity the merits of a man whose name, I trust, never will, and never can be forgotten!" At the conclusion of his speech, the Duke presented Herschel with a fine vase. Replying to the toast, Herschel said: "Perhaps it may be expected of me, that I should say something of what I have done among the Southern stars . . . I believe there is scarcely a corner in that part of the southern sky which I have not twice searched over, with almost the power of a microscope, and it may be easily supposed in the course of a rummage of that kind what an extraordinary turn out there must have been".

Biot on Polarized Light

In the *Athenæum* of June 16, 1838, is a note which says: "M. Biot in a memoir read to the Academy of Sciences, proposes the application of polarized light to detect the variations in isomerical substances; among several instances this distinguished philosopher adduces, gum arabic, which when dissolved in water gives a rotation of molecules to the left, but in applying sulphuric acid, this rotation gradually changes to the right, while a precipitate is found at the bottom of the vessel which contains it. M. Biot suggests the test of polarized light to all chemical combinations as opening a new and extensive field of the most delicate observations. Would it have been believed, says M. B., some years back that the impressions produced by the vibrations of a musical instrument on liquids in motion, should be the best means of evincing the physical mode of operation by which their flowing is operated."

Societies and Academies

London

Royal Society (*Proc.*, A, 166, May 19, 1938).

T. H. Havelock : The lift and moment on a flat plate in a stream of finite width.

J. de Graaff Hunter : Some experimental observations for longitude made by theodolite fitted with a shutter eyepiece.

L. Landau and G. Rumer : The cascade theory of electronic showers.

W. Cochrane : Polish on metals.

H. G. Howell and N. Coulson : The spectrum of thallium chloride.

F. Hoyle : β-Transitions in a coulomb field.

A. C. B. Lovell : The electrical conductivity of thin metallic films. (3) Alkali films with the properties of the normal metal.

P. L. Kapur and R. Peierls : The dispersion formula for nuclear reactions.

G. S. Rushbrooke : A note on Guggenheim's theory of strictly regular binary liquid mixtures.

Alex Müller : The dielectric polarization of a long chain ketone at constant volume and variable temperature.

Dublin

Royal Dublin Society, April 26.

G. F. Mitchell : A recent bog-flow in County Wicklow.

A. G. G. Leonard : A preliminary account of investigations on atmospheric pollution in Dublin. Systematic measurements of deposited solids have been carried out for the first three months of this year, and show that the solid matter falling on Leinster Lawn (Dublin City South) was deposited at the rate of 50 tons per square mile in that time. This included about 17 cwt. of tar. The rainfall during the period was 3·94 in.—an exceptionally low figure. Measurements of suspended impurity have been made hourly during February and March; the results obtained show a close approximation to those found at Westminster during winter months. Pollution due to sulphur showed a slight decrease from January to March.

Paris

Academy of Sciences, April 11 (*C.R.*, 206, 1153–1206).

Henri Deslandres : The universal constant of band spectra. The attribution of the lines of the band to causes other than the rotation of the molecule.

Georges Giraud : New extension of a type of problems relating to equations of the elliptic type.

Marcel Brelot : The problem of Dirichlet and sub-harmonic functions.

Boris Germansky : The systems of Fekete points of an arc of a circle.

Léopold Escande : New theoretical researches on flow through an immersed gate valve.

Mme. Marguerite Moreau-Hanot : The transport of ions by a gaseous current. The expansion of an ionized gaseous column.

Hans von Halban, jun. : The energy and intensity of the photoneutrons of beryllium and of deuton.

Roger Servant and Belling Tsaï : A direct reading apparatus for the measurement of magnetic fields.

Pierre Lambert and Jean Lecomte : The infrared absorption spectra of isomeric fatty hydrocarbons. Data are given for two isomeric pentanes and 17 isomeric octanes. The infra-red absorption spectra between 500 and 1,450 cm.$^{-1}$ can be utilized for the identification of the hydrocarbons in mixtures.

Marcus Brützcus : The structural formulæ of unsaturated hydrocarbons.

Etienne Canals and Pierre Peyrot : The Raman spectra of some crystalline powders.

Louis Roger : The study of a complex compound of lead and lithium iodides.

Maurice Marie Janot and Robert Goutarel : Corynantheine.

Denis Duveen : Anionotropic changes of the (+) and (−) α-phenylallyl alcohols.

W. S. S. Ladell : Effect of alcohol and alcoholic extracts on growth of tissues *in vitro*.

J. F. Schofield : A preliminary study of the prehistoric beads of the Northern Transvaal and Natal.

F. Rich : Some Transvaal desmids.

Geneva

Society of Physics and Natural History, March 17.

René de Saussure : The structure of geometries in Euclidian space of three dimensions. The author gives an account summarizing his works on geometry published in the "Archives des sciences physiques et naturelles" of Geneva from 1898 to 1921. These works have led to the creation of two new geometries, that of the "feuillets" and that of the "feuillets-cotés".

Georges Tiercy : The solution of the equation of the transfer of energy and the problem of radiative equilibrium. The object of this note is to establish, by a calculation different from the usual one, a known formula giving the value of the intensity of the radiation as a function of the opacity.

Georges Tiercy and Charles Golaz : The velocity of the wind as a function of the altitude. Is an approximate solution, with η constant, suitable ? This question is answered in the negative, since the solution would then contain only periodic terms, and this is not in agreement with observation.

Paul Rossier : (1) The identity of the hypotheses of Armellini and Russell on the theory of the colour index. The first assumes the constancy of the effective wave-length, the second the concentration of the sensibility of the eye on one unique wave-length. These two systems are equivalent. (2) The isodiametric curves in a Hertzsprung-Russell diagram. These curves are practically parallel straight lines.

Emile Cherbuliez and Mlle. Maria Fuld Researches on the acidolysis of esters. The study of the displacement in an ester of the acid radical by that of another acid (acidolysis) shows that the mechanism of this reaction is not that of the saponification of the ester by the traces of water always present in these substances entering into reaction, a saponification which would be followed by an esterification of the free acid added by the alcohol resulting from this saponification. This conclusion follows from the fact that gaseous hydrogen chlorine, which accelerates both reactions (esterification and alcoholysis), is without action on acidolysis.

Don Zimmet : Ascorbic acid, acetylcholine and the blood pressure. Small quantities of acetylcholine produce a marked lowering of the blood pressure when this substance is introduced into the body by intravenous injection. This effect may be largely diminished or even completely prevented by subsequent intravenous injections of ascorbic acid.

S. N. Aleshin and E. Igritskaia : Availability to the plant of phosphates adsorbed by soil.

F. D. Skaskin : Concerning the physiology of the critical period. The lack of water in the soil.

V. G. Alexandrov and O. G. Alexandrova : Structure of shrivelled ('meagre') grains of hard wheat.

D. M. Steinberg : Comparative data on wing regeneration in butterflies.

Rome

National Academy of the Lincei (*Atti*, 26, 305–354 ; 1937).

U. Cisotti : Sources in disperse media.

N. Obrechkoff : Zeros of some polynomials.

G. Facciotti : Concerning the 'asphericity' at an ordinary point of a surface.

F. Fiorentini Campolieti : A particular dynamic solution of the cosmological problem (1).

G. Lampariello : Extension of Jacobi's virial theorem and relationships of minimum kinetic energy.

E. Volterra : Calculus of arched suspension bridges.

O. Zanaboni : Concerning the approximation due to de Saint-Venant's principle in isotropic prismatic solids.

E. Ghigi : Constitution of Liebermann's benzanthrone.

V. Paroli : Observations on the embryology of *Tamarix gallica* L.

Atti, 26, 355–432 ; 1937.

T. Levi-Civita : Families of isoparametric surfaces in ordinary Euclidean space.

O. Scarpa : Cathodic growths which are observed in the electrolytic refining of tin.

P. Vincensini : A class of convex functions.

C. Pauc : Triangular inequality in the generalized spaces of Minkowski.

N. Aronszajn : Some problems concerning the spaces of Minkowski and the general vectorial spaces.

F. Fiorentini Campolieti : A particular dynamic solution of the cosmological problem (2).

G. Lampariello : Substantial variations in the motion of a continuous system.

F. Tricomi : Theory of the elastic arc with a circular directrix.

G. Zanotelli : The form of the vibration of light in a medium subjected to an alternating magnetic field.

P. Guareschi : Considerations concerning molecular potential energy (1). Calculation of molecular heats of liquids (2).

G. Tedeschi : Rate of dissolution of lead in acids (3).

V. Montoro : Preferential orientation of crystallites in some abnormal deposits of electrolytic copper.

A. Corradetti : An Asiatic species of *Anopheles* found in Abyssinia (*A. dthali* Patton, 1905).

V. Puntoni : Studies of the genus *Trichosporon* Behrend.

U. Amaldi : Memorial lecture on Salvatore Pincherle.

Vienna

Academy of Sciences, January 27.

S. Meyer: Radioactive constants of uranium and radium.

H. Hausner: (1) Relation between irradiation and photosynthesis in *Elodea densa*. Empirical formulæ are given for the gas evolution as a function of the duration of illumination and for the rate of evolution of gas as a function of the intensity of illumination. (2) Variation of the production of oxygen with the intensity of illumination in photosynthesis by *Elodea densa*. The percentage of oxygen in the evolved gas increases steadily with the intensity of illumination.

E. Melan: Distribution of stress in a Mises-Hencky continuum.

K. Graff: Selective absorption in the neighbourhood of Cassiopeia. The existence of one, or possibly two, absorbing clouds is deduced from the variation of colour excess with distance. The density of the cloud shows that it is not gaseous, but dust-like.

A. Kailan and F. Kunze: Action of ultra-violet light on halogen substituted fatty acids in aqueous solution. The quantum yield and dissociation constant are found for fourteen acids.

R. Skrabal: Velocity of saponification of methyl di- and tri-chloracetates.

M. Pestemer and H. Flaschka: Influence of the position of the substituent on the ultra-violet absorption of benzene chromophores (3).

Washington, D.C.

National Academy of Sciences (*Proc.*, 24, 107–164, March 15).

A. G. Steinberg and M. Abramowitz: The bar 'locus' and the $v+$ reaction in *Drosophila melanogaster*.

H. S. Jennings: Sex reaction types and their interrelations in *Paramecium bursaria* (1). Four sex reaction types have been discovered in two clones under investigation. Individuals of any one type will clot and conjugate only with individuals of the other three types. (2) Clones collected from natural habitats. Examination of clones obtained from different localities showed nine sex reaction types, falling into two independent groups the members of which do not conjugate with each other.

C. M. Osborn: Role of the melanophore-dispersing hormone of the pituitary in the colour changes of the catfish. Experiments on reactions to black, intermediate and white backgrounds of fish from which the pituitary has been removed indicate that this hormone causes about two thirds of the darkening reaction. Removal of pituitary does not inhibit colour change, but limits the range of shades the fish may assume.

W. J. Crozier, E. Wolf and Gertrud Zerrahn-Wolf: Duplexity theory of visual response in vertebrates. Plotting flicker frequency against log critical intensity for a turtle gives a smooth probability integral curve. There is no 'rod-effect' hump shown by similar curves obtained with other vertebrates, and this fact is correlated with the absence of rod cells from the retina of the turtle.

W. J. Crozier and A. H. Holway: Law for minimal discrimination of intensities (3). Experimental results on visual intensity discrimination support the view that the observed variations are due primarily to the fluctuating reactive capacity of the organism rather than to experimental error.

C. P. Haskins and E. V. Enzmann: Determination of the magnitude of cell 'sensitive volume' associated with the white-eye mutation in X-rayed *Drosophila* (3). Plotting percentage of affected eyes against duration of irradiation with a single wave-length of X-rays at 4°, 26° and 46° C. gives for males a straight line. That for females is different. The minimum limiting volume of a single locus for white eye is found to vary from $1\cdot 09 \times 10^{-18}$ to $1\cdot 50 \times 10^{-18}$ c.c. at 4° and 46° respectively.

W. J. Robbins and F. Kavanagh: Specificity of (1) pyrimidine and (2) thiazole for *Phycomyces Blakesleeanus*.

H. Shapley: Problem of the expanding universe. A discussion of a survey of the galaxies to the eighteenth magnitude in the south galactic polar cap, from plates made with the 24-inch Bruce doublet at Bloemfontein, and other data, leads to the view that there is, at present, no need to dispute on the grounds of nebular counts the attribution of red-shift to recession.

G. Birkhoff. Dependent probabilities and spaces (1).

E. Hille: Semi-groups of transformations in Hilbert space.

M. Ward and R. P. Dilworth: Residuated lattices.

Forthcoming Events

Wednesday, June 15

Board of Greenkeeping Research, at 10.—Annual Conference and opening of the Permanent Implement Exhibition at the St. Ives Research Station, Bingley, Yorkshire.

Thursday, June 16

Royal Society, at 4.30.—Prof. C. K. Ingold, F.R.S.: "The Structure of Benzene" (Bakerian Lecture).

International Conference of Naval Architects and Marine Engineers, June 16–18. To be held in London.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Headmaster of the Schofield Technical Institute, Mexborough—E. B. Stockdale, Education Office, Mexborough (June 18).

Assistant in Electrical Engineering in the Stockton-on-Tees Technical School—The Director of Education, Shire Hall, Durham (June 17)

Two Lecturers in the Civil and Mechanical Engineering Department of the Woolwich Polytechnic, London, S.E 18—The Secretary (June 17).

Lecturer in Metallurgy in the Sir John Cass Technical Institute, Jewry Street, Aldgate, E.C.3—The Principal (June 18).

Lecturer in Chemistry in the Acton Technical College, High Street, W.3—The Principal (June 24).

Assistant in Statistical Research in the University of Cambridge—The Secretary, Faculty of Economics, Marshall Library, Downing Street, Cambridge (June 27).

Junior Scientific Officer at the Building Research Station, Garston—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (June 27—quote J. 38/6).

Teacher of Metallurgy in the Medway Technical College—The District Education Officer, Fort Pitt House, New Road, Rochester (June 30).

Principal of the Municipal College of Technology, Manchester—The Director of Education, Education Offices, Deansgate, Manchester, 3 (June 30).

Assistant Lecturer in Organic Chemistry in the Manchester Municipal College of Technology—The Registrar (July 11).

Plant Physiologist and a Plant Pathologist to the Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, London, S.W.1 (July 15)

Professor of Physiology and a Professor of Pure Mathematics in the University of Cape Town—The Secretary, South Africa House, Trafalgar Square, London, W C.2 (July 23).

Senior Lecturer in Electrical Engineering in the County Technical College, Mansfield—The Principal.

Philosophy of World Affairs

THE impressive appeal for national unity which Mr. Eden uttered at the annual banquet of the Royal Society of St. George contained many passages which should appeal particularly to the scientific worker. Recalling the rectorial address at St. Andrews in 1934 in which General Smuts emphasized the threat to freedom and self-government even then offered by the new experiments on the Continent, and pleading for freedom not as an abstract political ideal but as a creative force inspiring youth to noble action, Mr. Eden reminded his audience that to uphold our ideals and our conception of life called for an effort and a spirit comparable with that made by the totalitarian States for their own purposes. For our faith in freedom, in toleration, in justice, the rule of law and co-operation, we should be prepared to make every contribution in our favour.

The threat to freedom of thought and speech and action grows ever greater, and the danger to-day is that in those countries which cherish liberty and democracy, the organization of defence and a common front against aggression itself tends to develop threats to freedom, which are more insidious even if closely allied to those encountered in the totalitarian State itself.

This factor, to which Walter Lippmann directed attention in his striking book "The Good Society", renders it imperative that the common effort called for from the democratic nations shall have a moral basis. This is not only the surest corrective to the insidious tendency to love "bondage with ease than strenuous liberty", but also the firmest basis for national unity.

There are no two opinions as to the supreme importance of promoting international understanding and good will, nor at the present time as to the importance of rearmament. On all sides, any policy which will lead to an appeasement of national jealousies and relieve political tension is welcomed. It is another question, however, if the expedients adopted prove obstacles in the way of that mutual trust and respect for treaty obligations in the dealings of civilized peoples with one another, upon which alone, as the Covenant of the League proclaims, relations of justice and good will can be permanently established.

The internal success of the totalitarian States has already exposed very clearly their limitations and provoked serious doubts as to how much can be hoped for from planning even in a democratic State. It is not the least service of Walter Lippmann's study of collectivism that he shows clearly its dangers even in a democratic regime. Lippmann indeed contends that planning is impossible in a true democracy, and that it depends on the authoritarian principle, which is a rejection of the wisdom of experience and the acceptance of errors which previous generations had learnt to discard.

Lippmann's contention, however unpalatable as it may be to most schools of political thought, contains too much truth in it to be lightly disregarded. Mankind unquestionably has advanced in knowledge, in the mastery of Nature, in unity, and in personal security through a progressive emancipation from the bondage of authority, monopoly and special privilege. The scientific achievements which have confronted us with some of our acutest difficulties to-day, and which by some are regarded as compelling the establishment of authority, even as they extend its power and range, have indeed become possible only as scientific inquiry was emancipated from authority. Scientific workers already have before them uncomfortable examples of the decay of scientific thought under the authoritarian regime.

If it is by the removal of restraints, rather than by constraints, as Lippmann suggests, that men have been able to adapt themselves to the life of great societies, there is none the less no more vital problem confronting democracy than the selection of just those constraints which are essential to its security without endangering the freedom from which its vitality springs. Because to plan every detail, as in the totalitarian State, means death to individuality and progress, we are not to assume that planning has no place in a democracy. No municipality, no rural or urban community, could avoid disaster for long without some manifestation of the foresight and prevision implicit in the idea of planning. Water supply, food supply, health, transport, and even recreation, all demand a quantitative conception of the needs of a community, and an organized attempt to meet those needs.

What therefore is demanded that our planning shall have some conception of man's spiritual needs, some regard to moral values and be based on co-operation and legislation rather than command. It is the type and purpose of our planning that are vital, and the tragedy of to-day is that the effort being made to eliminate waste, to conserve national resources and to meet national needs, is so often dominated by ideas and purposes that threaten world disaster and violate the moral and spiritual needs of mankind.

Nowhere is this truer than in the international sphere, and Senor de Madariaga's recently published outline of a world commonwealth vividly attests this truth. The most urgent task, as he sees it, is to teach world opinion to appreciate that the only way out of chaos is to lay the foundation for a world community which might establish enduring peace, the inner nature of which is justice. Nationally, as internationally, the problem is fundamentally one of education. When all the resources of the totalitarian State are directed to the mass education of its citizens for nationalist purposes and individuality is warped or crushed, the chief hope of civilization lies in the education of public opinion elsewhere to the need for and possibilities of world co-operation, and in a way which may yet win the consent of the totalitarian regimes themselves.

Effective thinking on the part of the individual voter is indeed the final condition of success, and the realization that there are no longer foreign affairs but only world affairs, that it is now the world that matters and not merely those foreigners who do not belong. Even ministers of world affairs cannot solve the problems raised by those affairs unless and until they combine in a permanent system for carrying them on by constituting, either in the present League of Nations, a reformed League, or a different League, a world council for foreign affairs, which must have behind it, to be effective, a powerful élite of world citizens endowed with the necessary world patriotism to give these world statesmen their inspiration and guidance.

That is essentially the argument of Senor de Madariaga in both his books, whether as in "The World's Design" he is outlining his vision of a world commonwealth or, in "Theory and Practice in International Relations"*, discussing its practicability. Nor is his outlook unhopeful. The mere existence of a machinery of world government in the League is a symbol of unity around which much may coalesce. Senor de Madariaga points also to other factors accelerating progress—the success already achieved in international co-operation in those fields such as health and communications, where the professional interest in getting the problem solved is dominant: the slow creation of a community spirit: the moral pride which makes nations compete for the place of the most virtuous at least in international assemblies.

However threatening the situation may be, it is at least not one for despair, and it throws down a challenge not least to scientific workers. They must make their contribution to the evolution of a philosophy of world affairs in which the elements of competition, co-ordination and organization are brought into a more intelligent and co-ordinated synthesis, which preserves man's moral and intellectual freedom while ministering to his material needs. They have their professional contribution to make in special fields involved in the positive planning visualized by Senor de Madariaga, such as the establishment of a world administration for mandated territories, a world bank and a world trade commission. On them rests the responsibility for much of that research in social problems upon which such co-ordination must be based, and they can at least play a part in the education of their fellows to a vision of world affairs, the consideration of problems from the point of view of an organized and conscious mankind. The ethical declaration for the times recently issued (see

---

* Theory and Practice in International Relations. By Salvador de Madariaga. (The William J. Cooper Foundation Lectures 1937, Swarthmore College.) Pp. v+105. (London: Oxford University Press, 1937.) 6s. net.

NATURE, May 7) appears at a timely moment, and claims the allegiance and active support of all scientific workers. All that is noblest in the tradition of science urges them to make their contribution to the primary spiritual problem of creating a historical consciousness of mankind as organized dwellers of the earth and the methodical expression of it in a world State. For only as the method and energy of intelligent mankind bring order into the present chaos of man's activities can their great heritage of truth, justice, toleration and liberty be preserved for mankind.

Science in the Service of Man

Science for the Citizen: a Self-Educator based on the Social Background of Scientific Discovery. By Lancelot Hogben. (Primers for the Age of Plenty.) Pp. 1120. (London: G. Allen and Unwin, Ltd., 1938.) 12*s*. 6*d*. net.

THIS is no ordinary book. Like its predecessor, "Mathematics for the Million", it is a portent of a new understanding and a new purpose in science. We have had in plenty popular expositions of scientific discoveries; we have had attempts at the analysis of the history of science; we have had essays on its social implications; here we have all three together. They gain immensely from being presented as a unity and worked out by a single mind. In this new primer of one thousand pages, Prof. Hogben sets out to teach, to chronicle and to preach the gospel of science.

In his first main purpose, Prof. Hogben succeeds admirably. The presentation of science to the layman has rarely been at the same time so attractive and so comprehensive. Here the unity of conception of the work, the idea of science in the service of humanity, has led to an admirable balance between different branches of science, and has even succeeded in presenting science without the division into set subjects that has been the curse of its teaching throughout the last century and a half. The simplicity and directness of the explanations, and Horrabin's numerous and attractive figures, should ensure for it an even greater popularity and usefulness than had "Mathematics for the Million". The very fact that science is not presented as an explanation of the wonders of the universe but as a means to practical handling of everyday necessities should give it a wide appeal to young and active minds. In one respect, however, there is a relapse towards the older tradition of teaching. The chapters are followed by examples for working out, which are bookwork and calculations and not experiments. The audience for which Prof. Hogben is writing will surely want to do things and not only to work them out on paper.

Quite apart from its other values, "Science for the Citizen" would have to be read for the account it presents of the history of science. Here Prof. Hogben is following the modern tradition of relating the developments of science to social needs. In doing so he has given a new life and a new meaning to the records of the past and made sense of what was before merely a catalogue of mental achievements. For example, the great biological developments of the nineteenth century, the idea of evolution and the discovery of the mechanism of heredity seem no longer isolated advances but part of a renewed interest in the biological and mineral resources of the world, which were opened up by the new means of the industrial revolution, and of the need to improve stocks of animals and plants for the benefit of rapidly growing populations. Necessarily the account is abbreviated and selective, but it contains much new material and will set all scientific workers thinking of how much more needs to be done to make the history of their own fields something alive and able to point the way to future discoveries.

Prof. Hogben distinguishes clearly between three factors in the advance of science: the opportunity, the means and the motive. The opportunity lies in the social circumstances of the time, which are propitious or not to the advance of science; the means are those practical and material techniques drawn from industry or from other parts of science, without which research is impossible; the motives determine the setting of the problem and the concentration of the scientist's attention on it.

> "Whether we choose to call it pure or applied, the story of science is not something apart from the common life of mankind. What we call pure science only thrives when the contemporary social structure is capable of making full use of its teaching, furnishing it with new problems for solution and equipping it with new instruments for solving them. Without printing there would have been little demand for spectacles; without spectacles neither telescope nor microscope; without these the finite velocity of light, the annual parallax of the stars, and the micro-organisms of fermentation processes and disease would never have been known to science. Without the pendulum clock

and the projectile there would have been no dynamics nor theory of sound. Without the dynamics of the pendulum and projectile, no Principia. Without deep-shaft mining in the sixteenth century, when abundant slave labour was no longer to hand, there would have been no social urge to study air pressure, ventilation and explosion. Balloons would not have been invented, chemistry would have barely surpassed the level reached in the third millennium B.C., and the conditions for discovering the electric current would have been lacking" (page 17).

It is, however, in the moral he draws from the study of present and past science that Prof. Hogben is at his best. In his own vigorous and inimitable style, he attacks what seem to him to be the enemies of both science and humanity, and points the way to effective social utilization of the results of science. To him, now as in the past, one of the chief enemies of science has been the use of deductive logic from self-evident principles. This legacy of Aristotle, which the physical sciences have managed to shake off, still hampers and distorts the social sciences and particularly the vital social science of economics.

"The past history of human culture shows that a high level of scientific attainment in isolated fields has flourished when men have been forced to bring their beliefs to the bar of fact and use them as recipes of social conduct. That the social sciences have not passed out of the stage from which the natural sciences were emerging in the time of Kepler is sufficiently evident from the following exposition of 'The Nature and Significance of Economic Science' by Prof. Robbins, which ends: 'In the last analysis, therefore, our proposition rests upon deductions which are implicit in our initial definition of the subject matter of Economic Science as a whole.'

"This passage briefly summarises every attitude to knowledge discarded by the natural sciences in reaching the prestige they now enjoy. The natural sciences owe their prestige to the fact that they provide man with the means of regulating his social conduct. They are able to do this because science rests on a wholesome distrust of logic, except in so far as the results of a logical process are tested continually by return to the real world" (pages 217–218).

The other enemy is introspective mysticism, the denial of the possibility of dealing in practice with the forces of Nature and society.

"The story of man's conquest of Substance and of Power will make it clear that we have reached a situation in which social machinery can no longer accommodate rapid advance in discovering the material amenities which science confers. We are thus faced with two alternatives. One is to devise the social machinery which will ensure the further progress of science by finding social uses for new discoveries. The other is to discredit confidence in the fact-loving method of science. This can be done most effectively by surrounding the work of the scientific investigator with an air of mystery, so that he fulfils the role of the first men of science in human history. The ancient calendar priests were the first scientists and the first civil servants. They ceased to be scientists as they aspired to become masters. The world tires of its masters and finds a growing need for efficient civil servants. So we may hope that the adventure of human knowledge will survive all the efforts to reinstate mysticism in the present period of cultural decay" (page 349).

Behind these two evils he sees the self-interest and greed of ruling minorities, who rather than lose their position will hold back the benefits which science could give to humanity.

"Science for the Citizen" avoids conventional divisions; it follows an order which is neither strictly that of subject nor that of time. It tends to deal first with the simpler mathematical and mechanical sciences and then leads through chemistry to biology. At the same time it tells the story of man's increasing understanding and control over Nature from the beginning of calendar lore at the dawn of history through the conquest of power and matter in the last century, to the beginning of the understanding of our bodies and our society in our own days.

The book is divided into five parts. The first: the conquest of time reckoning and space measurement, covers astronomy, mechanics and optics. For the first time, positional astronomy is presented with the full richness of its social background, and we understand why this apparently remote subject was of such practical and vital interest. One may wonder, however, whether Prof. Hogben's attempt to bring back "the use of globes" into teaching will be successful. These things were important, but for the ordinary city dweller of to-day the stars might just as well not exist.

The second section: the conquest of substitutes, tells the history of chemistry. It does full justice to the great revolution of the eighteenth century, which arising from the needs of the technical problems of the miner and cloth worker, laid the basis of our knowledge of chemistry. It traces the laying of the mysterious 'spirits,' through the operations of which men could escape from thinking concretely about material processes. It is, nevertheless, the least satisfactory part of the book, and the chapter on organic chemistry might well be rewritten in future editions, because though a competent account, it appears in its setting definitely dull.

The section on the conquest of power tells the story of the steam engine and electricity, and does it very well. The ideas of work and energy are fundamentally industrial and economic ideas; to understand them we need to call up again, as Prof. Hogben has done, the atmosphere of enterprising capitalism of the industrial revolution. It is, however, in the next section, the conquest of hunger and disease, that Prof. Hogben really comes into his own. Its two hundred pages are a triumph in the presentation of the whole of biology. Physiology, heredity and evolution fall naturally into their places, and the balance of the different aspects of the subject is well preserved.

In the last section, the conquest of behaviour, Prof. Hogben discusses psychology and the problem of nature and nurture, and draws his social conclusions in a final chapter which would stand by itself as an exposition of the modern outlook of the scientific worker.

Scarcely any scientific worker will agree with everything that is in this book; many will disagree violently with a great deal of it. It offers an easy target to detailed criticism, but most of this criticism will be beside the point. When a man is trying to do something that has been done before we may justifiably say it is well or badly done, but when he is doing something that has never been done before, the important thing is the actual creation, not the defects in it: afterwards, other people may avoid the mistakes and manage things better, the essential thing is to make the first attempt. The very novelty of the task that Prof. Hogben has attempted imposes its own limitations. It would be impossible for him to be equally successful over the whole field; certain parts are definitely weak, in others personal prejudices and predilections would seem to distort judgment. It is a pity that in spite of the several hands through which the manuscript has been, a large number of errors should remain in the text and in the illustrations. Most of them, it is true, are trivial, but one or two of them show that Prof. Hogben has not quite succeeded in the superhuman task of making all science his province.

The historical interpretation is the most difficult to appraise justly because here no one is in possession of enough of the facts, and the inevitable selection gives a definite bias to the work. It would seem to the reviewer, for example, that the importance of chemistry has been consistently underrated. Another more general criticism is the absence, except in the case of genetics, of any account of modern science and particularly of the revolution in physical science of the present century, which in the light of history will probably seem more important than those of the seventeenth and nineteenth centuries. It is true that this revolution has not made its effect felt in practice, but the absence of any mention of it gives the whole book an unexpectedly old-fashioned appearance. On the social side it would seem questionable to the reviewer that it is possible to achieve a rationally run society by the abandonment of localization of industry and by the social control of new industries alone. We are a long way yet from the time when every portion of the earth's surface might have equal natural potentialities or when heavy industries, coal, iron and power, will have ceased to be the keystone of the productive system.

It is made apparent throughout the book that it is the present system that is holding us back. On the kind of system that is needed to replace it Prof. Hogben is equally clear, but on how to get it he has very little to say, perhaps advisedly. The problem has been set; it is for the citizens rather than the men of science to solve it.

"Science for the Citizen" is full of new and suggestive ideas. No scientific worker after reading it can avoid looking at his work in a different way. It does not treat of deep philosophical questions, but instead gives us clear and practical directions, much more congenial to the English mind. These few sentences express plainly what chapters of learned works will find difficult to conceal:

> "Science is not a photographic picture of the real world which exists independently of our views about it, and will continue to exist when we are no longer part of it. It is an ordnance map which guides us in finding our way in it" (page 329).

> "The truths of science are recipes for human action, and science flourishes when it is actively ministering to social needs. It advances conspicuously in periods when men and women are actively engaged in rational endeavour to change their social environment, and is held back when those who participate in it are too anxious to find rationalisations for privilege or political strategy" (page 1057).

These ideas have been too much neglected in the past; it is for us to understand them and make use of them in planning science in the future, a science that can no longer proceed consciously indifferent to its potentialities for human welfare and the need to realize that potentiality.

> "During the past century scientific knowledge has created new potentials of social organisation vastly in excess of anything for which the political education of mankind is prepared. Seventy years ago it was still possible to discuss whether poverty was morally tolerable or materially inevitable. It was still possible to discuss whether war was spiritually edifying or socially escapable. All this

is changed. Poverty in the sense in which it was then defined, the sense in which the word is intelligible to the social biologist, is not materially inevitable. War is not a moral picnic. It threatens to destroy the entire fabric of our civilisation, if we do not eradicate it with as much promptitude and ruthlessness as we have eradicated, or are eradicating, smallpox, malaria, and yellow fever" (page 1081).

Science is a part, and an essential part, of the great struggle in which we are all willy-nilly now engaged. It has something definite to offer, something which, in his conclusion, Prof. Hogben calls the New Social Contract.

"Advancing scientific knowledge has swept away many beliefs which sustained popular aspirations in the formative stages of modern democracy. . . . In their place modern science offers us a NEW SOCIAL CONTRACT. The social contract of scientific humanism is the recognition that the sufficient basis for rational co-operation between citizens is scientific investigation of the common needs of mankind, a scientific inventory of resources available for satisfying them, and a realistic survey of how modern social institutions contribute to or militate against human needs" (page 1089).

We may or may not like this book, but we cannot deny that it raises issues which we all have to face. J. D. B.

Plant Viruses and their Hosts

A Textbook of Plant Virus Diseases
By Dr. Kenneth M. Smith. Pp. x + 615. (London: J. and A. Churchill, Ltd., 1937.) 21*s*.

DR. KENNETH SMITH, having written an earlier volume upon the physiology and general behaviour of plant viruses, has recently completed another book with a pronounced taxonomic flavour. It is here possible to obtain, for the first time, a detailed conspectus of the whole number of plant viruses known at present.

One gratifying feature is that plant viruses are arranged upon a plan of classification which has already reached a considerable degree of success in the hands of Prof. James Johnson of Wisconsin University. Dr. Smith uses a slight modification of the Johnson classification, and employs the scientific generic name of the host, followed by a number, to denote a particular plant virus. Thus 'Nicotiana Virus 1' is the disease formerly known as tobacco mosaic. A list of synonyms is given for each disease, and the text is somewhat of the calibre of a critical fungus flora, in so far as it crystallizes one definite name from a number of varying designations. It is delightful to be guided among the formerly bewildering potato viruses by so sure a hand, and the relations of virus maladies upon tobacco and tomato also become clearer. Properties of each virus are given in relation to external physical and biological agents, to various methods of transmission, and to particle size. The diseases caused by the particular virus are described for the various host plants, and Hutchinson's classification is used both for this and in the general arrangement of the volume.

An appendix, which gives the most characteristic symptoms of virus diseases, is arranged alphabetically by the names of the hosts, and should be particularly valuable for general diagnosis. A chapter upon the insect vectors of plant viruses describes the various species, with all the resources of Dr. Smith's specialist work, and includes notes upon life-histories and geographical distribution. More than a hundred plates embellish the volume, and the author has enlisted the co-operation of numerous research workers in many parts of the world, to provide adequate pictorial representation of the subject. The extensive references to published work are further evidence for the completeness of knowledge collected in the present volume.

A text-book is usually an exposition of a science already organized; a portrayal of clarified thought which has withstood the test of continual teaching. Dr. Kenneth Smith's book actually does the organizing and performs the clarifying. It does more; for it provides a framework into which future results may be fitted. The scheme of classification is already sufficiently accepted by research workers in plant viruses, and is backed in the present volume by a wealth of description. It would seem inadvisable for any research worker to depart from it until the time shall have arrived when it will be possible to give each virus a more satisfactory binomial nomenclature. There is also, at the present time, sufficient information upon virus diseases of plants collected into volumes which are readily available, so that the subject might well enjoy a new popularity with the profession of teaching. Viruses are economically of greater importance, as causal agents of plant diseases, than are bacteria, and the volume under review removes the last excuse for a somewhat neglected exposition to students. Biography of Madame Curie

Madame Curie
By Eve Curie. Translated by Vincent Sheean. Pp. xii + 411 + 31 plates. (London: William Heinemann, Ltd., 1938.) 18*s.* net.

INTERESTED as we are in the sources of scientific creation, we must welcome the appearance of a book which is a touching example of filial piety and at the same time an excellent biography of one of the most eminent scientific workers of our epoch. It has considerable artistic and documentary value. I think it gives a fairly complete answer to the question how it could happen that a young girl from a foreign country was called to acquire a fame which made her name a symbol, and to become a leading scientific personality not only in her native and adopted country, but also throughout the world. In fact the book tells us of national, social and hereditary factors which contributed to the formation and development of the exceptional gifts of Mme. Curie's mind and character.

Very few of those who admire this great woman realize that in the second half of the past century women played a great part in Poland. Strange to say, this fact was due to the loss of independence and severe conditions imposed by the Russian domination. Political thought and national feeling were for the most part compressed into family life, with the result that women were often equal to men in assuming full civic responsibility. Another consequence was a great movement towards 'emancipation' and university education for women. Young girls often went abroad to study at a university. This tendency would certainly not be opposed in the highly cultivated Skłodowski's family where all told young Manya of the value of intellectual effort. The moral atmosphere was that of strenuous work, of sense of duty, of patriotism. Strength of will was her inborn quality—the photographs show it clearly on her "stubborn face"—but the experiences of her childhood and youth, the early necessity of earning her living as a governess, hammered this good material and made her a rare example of endurance and tenacity. The following fact illustrates the spirit of self-sacrifice which reigned in this family. When Bronya, the older sister, went to Paris to study medicine, the younger one helped her with money saved from her meagre salary and patiently awaited her own turn. When it came at last, she studied with passion, living confined in the "icy garret", ignoring world and pleasure. What moved her was the desire to be useful to her family, the faith in her abilities and something specifically Polish: ambition fed by the love for her country.

There is scarcely any other scientist's life which shows in such a striking way how great achievements in science are due to the association of moral and intellectual qualities. Of course it was remarkable scientific insight to conceive the idea of radioactivity as an atomic property, but the actual discovery of radium—and what was perhaps more difficult, its purification from two tons of ore—conducted in the famous shed in the worst conditions one can imagine, were only possible owing to the incredible tenacity of this delicate woman; and we still see this strength of will throughout Mme. Curie's later life. Her resolution to face the gravest responsibilities immediately after Pierre Curie's death, that terrible tragedy which might have broken even a strong man's nature, attained to heroism. No less heroic were her activities during the Great War, when moved perhaps by some ancestral influences, she organized, careless of danger, the then neglected X-ray examination of wounded soldiers both behind and practically in the lines of the French armies. Who could fail to admire her continual struggle against illness, the firm decision to work up to the last moment? One might say that she was taken almost directly from the laboratory to her deathbed.

All these facts belong perhaps more to the *vie romancée* than to a scientist's biography. But in Mme. Curie's life romance was mixed with science. When we read Mlle. Eve Curie's book, the beautiful account of the great days spent by the Curies at work, of their holidays, of misery and glory, we do not know what comes first: a story of love or of one of the greatest scientific discoveries of our times. Of the later scientific activity of Mme. Curie, the book tells us not as much as we might desire. This is not a reproach: Mlle. Curie is an extremely intelligent person and a brilliant writer, but she is not directly interested in science. A scientist is, after all, a human being and we want to know how race, milieu, physical and spiritual constitution show themselves in his life and activity.

I have watched Mme. Curie's work for years, but never understood it as well as after reading Eve Curie's book. May I express to her my personal thanks, which will also be shared, as I hope, by scientific workers throughout the world.

L. WERTENSTEIN.

Die Tierwelt Deutschlands und der angrenzenden Meeresteile nach ihren Merkmalen und nach ihrer Lebensweise

Begründet von Prof. Dr. Friedrich Dahl. Teil 31 und 32: Spinnentiere oder Arachnoidea. vii: Wassermilben oder Hydracarina (Hydrachnellæ und Halacaridæ). (1) Pp. x+288. 24 gold marks. (2) Pp. 289–574. 24 gold marks. Teil 33: Spinnentiere oder Arachnoidea. viii: Gnaphosidæ, Anyphænidæ, Clubionidæ, Hahniidæ, Argyronetidæ, Theridiidæ. Pp. ii+222. 20 gold marks. (Jena: Gustav Fischer, 1937.)

THE issue under notice of this well-known work deals with six families of spiders and is more substantial than any of its predecessors in this order. It includes descriptions of 169 German species, in 39 genera, with notes on their distribution, both in Germany and elsewhere, and full dichotomic tables for their separation. The classification used is that of Petrunkevitch, 1933; for example, the water spider, *Argyroneta*, occupies a family by itself. The illustrations are a striking feature of the work. There are more than 500 clear line diagrams of genitalia and other pertinent parts, which are invaluable for purposes of identification, and many of which have never been published before. The value of the work to British readers is very great. About ninety of the species described occur in Britain, all being mentioned as so doing, and as a help in naming the species of some of our most important families, this work far surpasses anything previously obtainable.

This is not so forcibly true of the two parts on water-mites, for the Ray Society publications of 1925, 1927 and 1929 have covered the same ground. Dr. Viets' work opens with thirty valuable pages on the habits of water-mites, and he also gives directions for collecting, preserving and mounting them. In the systematic portion, 441 species of German water-mites are described in 92 genera and illustrated by more than 650 clear diagrams. There is a greater uniformity of treatment here than in the part on spiders, which is the work of three contributors, but all three parts should be assured of a welcome proportionate to their undoubted value. T. H. S.

Annual Reports on the Progress of Chemistry for 1937

Vol. 34. Issued by the Chemical Society. Pp. xvi+540. (London: The Chemical Society, 1938.) 13*s*.

IN these annual reports, no attempt is made to present a comprehensive review of the year's chemical publications; to do so would result either in a volume of size so great as to defeat its purpose or in surveys so lacking in detail as to be valueless. Instead, these reports perform the much more useful and attractive service of providing a collection of "proofs of evidence by expert witnesses" concerning selected fields where researches of fundamental importance are being actively prosecuted.

The first report is devoted to radioactivity and sub-atomic phenomena. The second deals with non-radioactive isotopes, chemical kinetics, photochemistry, intermolecular forces and the properties of liquids, and electrochemistry. Inorganic chemistry is represented by chapters on sodium metaphosphates and polyphosphates, the rare earths, compounds of boron, halogen oxides, and the behaviour of elements and compounds at high pressures. Crystallography is represented by sections on lattice defects in polar crystals, crystal chemistry, the structure of liquids and amorphous solids, and molecular crystals. A report on the structure and stereochemistry of simple organic molecules is followed by others on general methods, free radicals, carbohydrates, proteins, triterpenes, heterocyclic compounds, porphyrins, and rubrenes and azulenes. There are substantial sections on animal and plant biochemistry, whilst analytical chemistry is dealt with not only from the general inorganic point of view but also in the special aspects of spectrum and of rock analysis. A. A. E.

John Locke

By Prof. R. I. Aaron. (Leaders of Philosophy Series.) Pp. x+328. (London: Oxford University Press, 1937.) 12*s*. 6*d*. net.

THIS excellent book on a thinker who is a classic in philosophy will give fresh impetus to discussion and controversy. It is not the first part of this work, which deals adequately with Locke's life, or the third part, where we find a good summary of Locke's views on moral philosophy, political theory, education and religion, which may be a ground of dissent; but rather the second part, which deals with the central points of Locke's psychology and systemology. The author's interpretation of the term 'idea', for one thing, scarcely helps to set one's mind at ease about Locke's meaning of this term. There is also the disturbing view that "we now find Locke asserting that sensation is itself knowledge for we know in it the existence of things" (p. 244), which is not supported by any quotations from the "Essay". The author's main purpose is to interpret Locke as a representationalist in his theory of ideas, a view which seems rather to restrict the aim and value of the "Essay". The brief reference made to Locke's views on the positive sciences are coloured by this interpretation. If this is allowed for, Prof. Aaron's book may be regarded as a notable addition to philosophical scholarship. T. G.

Sur les autres mondes

Par Lucien Rudaux. Pp. vi+222+20 plates. (Paris: Libr. Larousse, 1937.)

THIS work is a comprehensive and detailed account of the sun, moon and planets, intended for the general reader. The author adopts the historical method and leads the reader gradually to an up-to-date picture of each of the bodies concerned, with a carefully planned exposition of planetary phenomena. M. Rudaux is also a most accomplished artist and the book is profusely illustrated with diagrams and coloured plates, the latter being mainly imaginative reconstructions of the planetary and lunar scenes. As an example of his pictorial method, we may mention the aspect of Saturn and its rings as seen from one of Saturn's satellites. The author and publishers are to be congratulated on a really magnificent production. W. M. S.

Sewage Discharge and the Mersey Estuary*

Co-operation in Technical Research

THIS handsome and well-illustrated report on the Mersey estuary, which has been issued by the Department of Scientific and Industrial Research, is an example of the working of the best English tradition of co-operation in public affairs. It exhibits the Department in a part for which it is so well equipped—which it might be more often called upon to play—that of an arbiter to determine the scientific facts for the solution of a controversial problem of great public and economic importance. It shows the various public authorities of Merseyside agreeing, in spite of a conflict of interests, to co-operate in order to obtain an independent scientific inquiry; it also shows them evincing their confidence in the Department of Scientific and Industrial Research by inviting it to undertake the investigation. The Department asked the Water Pollution Research Board to be responsible for the scheme of the investigation; so, in a typically national way, another party to the co-operative work was a body of scientific men who gave honorary service.

The problem was the effect upon the estuary of the Mersey of the discharge into it of crude sewage from the large populations of Liverpool, Birkenhead and Wallasey, among others. The volume of the estuary is very great, and matters of health and amenity were not part of the inquiry. The problem was the narrower one of the effect of this discharge of sewage on the estuary as a channel of navigation. The opinion had been put forward that the presence of sewage increased the rate of sedimentation of solid matter in the water of the estuary, and by alteration of the character of the deposit increased also the difficulty of its removal by dredging. Such a possibility led naturally to some competition of interests between the corporations responsible for the sewage discharge on one hand and the authority responsible for the navigation and conservancy of the river on the other. The data for determining whether these possibilities were actualities were not available. Accordingly representatives of the various interests, after meeting in conference in 1932, decided, with admirable judgment, to ask the Department, as has already been stated, to investigate the matter and to give an authoritative pronouncement on the scientific facts. The local authorities and other authorities and companies concerned agreed to bear the costs of the inquiry, and agreed also that "on the issue of scientific fact the result of the investigation should be accepted as conclusive". The understanding come to was thus one which reflected great credit on all concerned, and was a signal mark of confidence in a Government Department. The agreed procedure, in the words of the preface, "might well be followed by others in dealing with controversial problems affecting many interests".

The investigation, which was begun in 1933 and lasted over a period of four years, consisted of a wide-reaching, hydrographical, chemical, and biological investigation of the effects of the discharge of crude sewage. The area to be studied embraced the navigable channels of Liverpool Bay, the tidal pool of the Upper Estuary—with a volume at high water of a spring tide of about 1,000 million cubic yards—and the Narrows which connect the two.

The Mersey Docks and Harbour Board has, since 1861, made quinquennial surveys of the capacity of the Upper Estuary, and its data show that during the period 1906–31 there was a decrease of about 52 million cubic yards. This reduction in capacity naturally led to the suggestion, already referred to, that the presence of sewage had been responsible, by bringing about a deposit of mud of such a consistency that it was not eroded by the tidal stream. In order to investigate this possibility, the records of hydrographical surveys of the Mersey made by the Mersey Docks and Harbour Board were examined, with other hydrographical data, to determine the positions and levels in the Estuary at which accretion and erosion had occurred during this period. The quantities and nature of the sewage and principal trade wastes discharged into the estuary were ascertained, the concentration of polluting substances in the estuary water under different tidal conditions was determined, and an estimate was made of the length of time spent by polluting substances in the estuary before passing out to sea. The concentration of mud and silt eroded by the tide from the bed and foreshore of the estuary and carried in suspension in the moving water was also determined.

Numerous laboratory experiments were then made to observe the effect of sewage on the rate of sedimentation of mud and silt under conditions similar to those which occur in the estuary. The factors studied included the concentration and state of division of the solids, the depth of water through which sedimentation occurred, the temperature and salinity of the water, and the effect of the addition of different proportions of sewage and of suspensions of bacteria derived from sewage. In some series of experiments before the rate of sedimentation of the solids was measured, samples of saline water containing mud and sewage in suspension, were stirred at different speeds, thus reproducing the conditions in the estuary, where water containing silt, mud and sewage-solids in suspension is carried to and fro by the tide.

---

* Estuary of the River Mersey. The Effect of the Discharge of Crude Sewage into the Estuary of the River Mersey on the Amount and Hardness of the Deposit in the Estuary. (Department of Scientific and Industrial Research. Water Pollution Research: Technical Paper No. 7.) Pp. xvii+337+8 plates. (London: H.M. Stationery Office, 1938.) 30s. net.

Numerous samples of mud and other solid matter for examination were collected from different parts of the Upper Estuary of the Mersey and from Liverpool Bay. For comparison, samples were also collected from relatively unpolluted estuaries and marshes in Norfolk, Suffolk, Essex, Devon, Monmouth, Cheshire and Lancashire, from the Firth of Tay in Scotland, Lough Foyle in the north of Ireland, from estuaries in Eire, and from the bed of the Irish Sea. The concentration of organic matter and the principal inorganic constituents were determined by analysis, and the relative resistance of the different muds to erosion by a moving stream of water was observed.

One of the most interesting results of the investigation was the conclusion that the most likely source of new mud entering the Mersey Estuary is the bed of Liverpool Bay and of the Irish Sea. As to the quantity of suspended inorganic matter contributed by the sewage, one can calculate from the volume of daily discharge (30–40 million gallons or 180,000–240,000 cubic yards) that the quantity of *inorganic* matter discharged *in a year* is less than 25,000 cubic yards, that is, less than 0·0025 per cent of the capacity of the Upper Estuary. It is also to be noted that the concentration of sewage in the estuary water is not high ; in the greater part it does not exceed 1 per cent by volume, and in no considerable volume of water does it exceed 5 per cent.

Another striking result obtained was that the concentration of organic matter in mud from the Mersey, usually less than 3 per cent, was *no higher* than that of samples of mud from the bed of the Irish Sea, from Liverpool Bay, and from *relatively unpolluted* estuaries, a number of which were examined. The composition of the mud, therefore, provides no evidence that sewage is responsible for its deposition.

The question of the precipitation or deposition of mud in the estuary was naturally of great interest, and one to which much attention was paid in the investigation. It was of course possible, as had been suggested, that there was some physical action between the suspended sewage and the suspended mud, leading to a co-precipitation of material. Elaborate experiments, first with salt water and later with the addition of sewage, were therefore undertaken on the rate of sedimentation of mud from the Stanlow Bank (which includes most of the mud in the Upper Estuary), of mud from Liverpool Bay, and also of muds from various relatively unpolluted estuaries. The result observed was that the rates of sedimentation in saline water of muds from the Stanlow Bank and from the bed of Liverpool Bay were similar, and they were on the whole rather lower than those of muds from a number of unpolluted estuaries. There was thus no evidence that in water without sewage the Mersey muds precipitated more rapidly.

The observations on the effect of sewage on the rate of sedimentation were of especial interest ; they indicate the importance of carrying out such studies under a wide range of conditions if erroneous conclusions are to be avoided. With small depths of fall, the addition of 5 per cent of crude sewage gave a slight but definite increase in the rate of sedimentation. When, however, the sedimentation was followed in columns of 40 ft., the sewage had no effect, although it is to be noted the concentration employed was far higher than that occurring in the estuary. The explanation appears to lie in the state of aggregation of the mud. In settling through such considerable depths as 40 ft., the mud aggregates into large clots with so high a consequent rate of settling that the effect of the sewage becomes negligible. That these conditions apply in the Mersey was shown by the observation that mud carried during the run of the tide in the estuary is generally in the form of large aggregates ; similar aggregates were found for the mud carried in suspension by the water of the comparatively unpolluted estuaries of the Rivers Suir and Barrow.

The question of the ease of erosion of Mersey muds was carefully investigated and from several aspects, though, as has already been stated, the most likely source of any large quantity of new mud which may enter the Upper Estuary is the bed of Liverpool Bay and the Irish Sea. There appeared to be little erosion of mud from the surface of the banks in the Upper Estuary, since these are mostly more than 20 ft. above Liverpool Bay Datum level and so are covered only near high water when the stream velocity is low. Considerable erosion often takes place, however, from vertical faces of a mud bank exposed to the full force of the tidal stream. By the use of a suitable laboratory method the 'erodibility' of mud from different sources was compared, with the result that with Mersey mud the resistance to erosion is *slightly less* than that of mud from estuaries in Suffolk and Essex which are comparatively unpolluted.

The data of dredging operations point in the same direction as studies of mud erosion. Dredging of the sea channels in Liverpool Bay has been carried on since 1880 and records of the operations are available. Those of two dredgers for the period 1909–35 were examined in detail, but the returns gave no evidence of any increase in the difficulty of dredging during those years.

With regard to the changes in capacity of the Upper Estuary; the report accepts the values put forward by the Mersey Docks and Harbour Board. The surveys by the Board show that between 1871 and 1886 the capacity rose by 48 million cubic yards, that is, by 5 per cent. Between 1886 and 1891 it declined by 5·5 per cent of the former value, but rose again in 1906; between that year and 1926 there was a loss of 5·2 per cent. The survey of 1936 shows an increase of capacity over 1931, the decrease on the 1906 value being only 4 per cent. The capacity was approximately the same in 1936 as in 1871, 1891 and 1916, so that the changes do not indicate any regular decrease in capacity with time, such as would be expected from a gradually increasing discharge of sewage.

Finally, results most illuminating for the points at issue were obtained by a consideration of the losses of capacity at different *horizontal* levels, and also of the distribution of mud and of sand. Half the loss of capacity was due to deposits below the level of Liverpool Bay Datum (L.B.D.), and only about 10 per cent to deposits above a level of 20 ft. above L.B.D. Mud, however, is found almost entirely on banks of a height greater than 20 ft. above L.B.D.; banks of lower height are comprised almost entirely of sand. It is thus plain that reduction of capacity does not coincide with the present distribution of *mud* banks.

From the report, it is thus evident that the answer to the question proposed needs no balancing of conflicting evidence. Converging lines of testimony have been drawn from (*a*) the amount of inorganic matter brought into the estuary from sewage, (*b*) the concentration of organic matter in the mud, (*c*) the effect of sewage upon the composition and rate of sedimentation of mud in the condition of suspension in which it is found in the water of the estuary, (*d*) the resistance to erosion of mud from the Mersey in comparison with that of muds from relatively unpolluted estuaries, (*e*) a comparison of the reduction of capacity in different parts of the estuary with the distribution of mud and sand. All these give an unequivocal negative to the question as to whether the discharge of crude sewage has had any effect on the amount and hardness of the deposit in the estuary.

This study of the Mersey Estuary should long stand as a classic one in the field of applied science, not only for the width and scope of the investigation but also for the decisiveness of its results and the civic importance of its findings. Its origin makes it a shining example to other public authorities who may similarly find themselves faced with controversial problems which can be solved by scientific analysis.

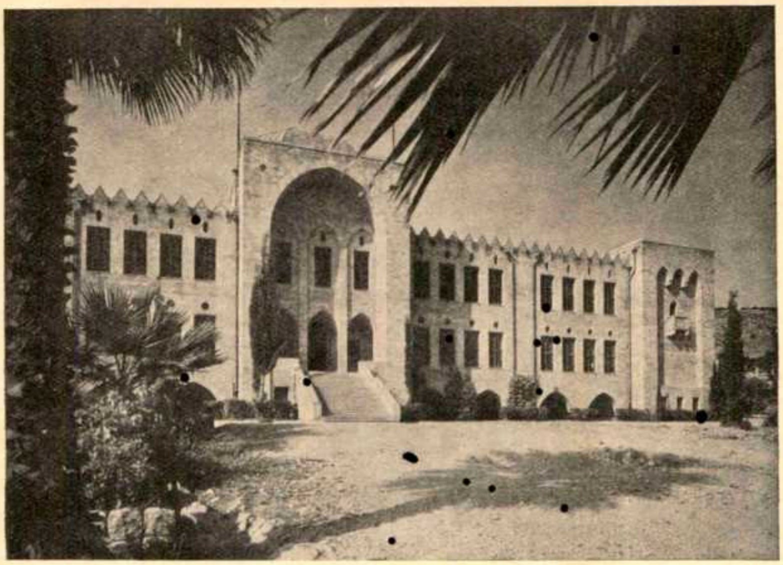
The Hebrew Technical Institute, Haifa*

THE Hebrew Technical Institute in Haifa is the centre of technical training and research for the young Jewish community in Palestine. Hebrew is the language of instruction, but the college is open to all, making no distinction of race or creed; and a few Palestine Arabs have availed themselves of this opportunity. The curriculum is extensive, and includes courses leading to university degrees in the technical college proper (500 students), a trade school for training skilled artisans and foremen (250 pupils), special vocational training classes for refugees, courses for agricultural workers, and evening classes. At present there are about a thousand students altogether; examinations are held under the supervision, and with the help of, the Palestine Government. The Institute was founded about thirty years ago; but, owing to the Great War, did not begin its academic work until 1924. Its progress offers an opportunity for the study of the effect of colonization on the development of an educational institution.

Colonization in Palestine does not mean the establishment of foreign trading stations on the coast-line, but the building up of a new national life in all its branches and with all its implications, in a limited area, and under the pressure of thousands of families from the countries of middle and eastern Europe forced to immigrate for economic, social or political reasons. The Jews left Palestine about two thousand years ago and can only return in larger numbers if, both in agriculture and in industry, they make the utmost use of the advances of pure and applied science. Owing to social prejudices and to legal restrictions imposed upon them by the people among whom they lived, the Jews were, for many centuries,

---

* A booklet "The Hebrew Technical Institute, Haifa; Its Achievements and its Aims (Haifa, 1938)" has just been published and will be sent, free of charge, on application to the Secretary of the Institute, P.O.B. 910, Haifa (Palestine), or to the Hon. Sec. of the Auxiliary Group of the H.T.I., (Mrs.) B. Buckman, 21 Willow Road, London, N.W.3.



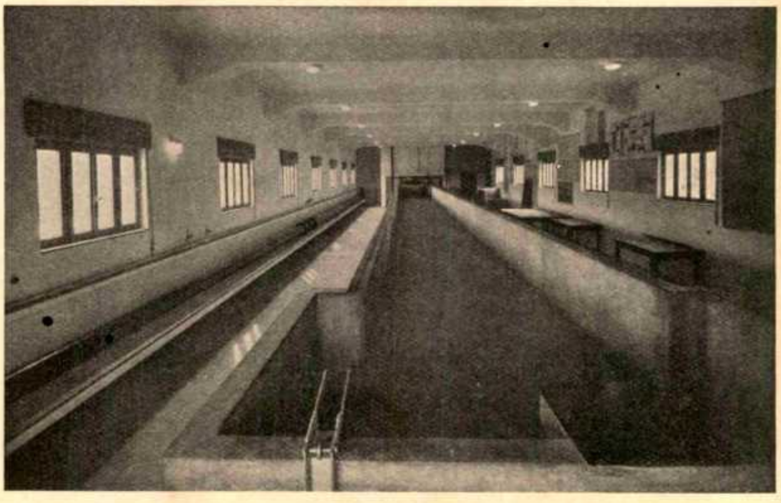
THE HEBREW TECHNICAL INSTITUTE, MAIN BUILDING

debarred from agriculture, trades and professions. In some eastern European countries, these laws were rescinded less than twenty years ago. They have to learn many things anew, and it is difficult to overestimate the importance of technical training in their return to the Holy Land. That they are capable and willing to learn, and that they have not lost their old vigour and enterprise is shown by such examples as the improved production of Jaffa oranges, the introduction of reinforced concrete in the construction of roads and buildings, the electrification of Palestine, and the extraction of potash, bromine and other chemical products from the Dead Sea.

When Jews first returned to Palestine in larger numbers, their first requirements were communication between settlements, houses to live in, reclamation of land, drainage of swamps, provision for water supplies, drainage of towns and villages, and the means of intensive agriculture. Therefore, the two departments first developed in the Technical College proper were those of civil engineering and architecture. With the further development of industry, a third, the Department of Industrial Engineering, was recently opened. This consists of two sections: one for electro-mechanical engineering, and one for chemical technology. The staff of this third department was largely recruited from German-Jewish men of science during the years 1933 and 1934. There are now nine working laboratories, which are used for teaching and research, and two more are being equipped. Besides the general science laboratories, mention should be made of the building materials-testing laboratory, the hydraulics laboratory (erected with the help of the Palestine Government, and probably the finest in the Near East), the metallurgical laboratory and those for electrical and chemical technology. Some laboratories are still housed in temporary buildings, and some are not yet completely equipped. But a good beginning has been made, and this appears to guarantee the success of future developments.

The Institute has just launched a campaign for an extension fund. The increasing number of students who apply for admission necessitates the opening of new departments in order to offer a greater variety of courses. The development of industrial life calls for an extension of research work in almost all branches of exact and applied sciences. Raw materials must be tested, new processes devised, known processes revised, and methods of production developed. The College has recently decided to open post-graduate classes for a limited number of students, in connexion with the expansion of its research departments, as post-graduate studies have often been a help and a stimulus to research.

There can scarcely be a better investment for the Jewish community than to support the



EXPERIMENTAL HALL OF THE HYDRAULICS LABORATORY extension fund of this Institute, which paves the way for the development of industry in Palestine in so many directions. The Institute prides itself on being almost self-supporting. Eighty per cent of its income is derived from tuition fees and fees paid by industry for the use of the laboratories. This is a very good record for an educational institution, and a closer analysis of its income immediately shows the reason for it. Last year's budget amounted to about £20,500. If one deducts from this a non-recurrent grant from the Palestine Government (ear-marked for new buildings and equipment), the income only amounts to £17,200. This is very small for an institution in which one thousand pupils are trained: it is obviously a starvation figure and must imply either curtailing teaching or research activities or both. The outside observer concludes, with a feeling of uneasiness, that the Jews in Palestine are about to repeat the mistakes of European countries against which men of science and engineers have been fighting in recent years. It is a grave mistake to distribute the income of a community in such a way that it is impossible for scientific institutions to develop all their resources. From the point of view of the present as well as of future generations, scientific work gives by far the highest return for money spent. Considering the particular circumstances of colonization in Palestine, and the small number of scientific institutions concerned, there is no reason why they should repeat errors which are only now being overcome in Europe and America.

There is one other point worth mentioning here. The library of the Hebrew Technical Institute is the only technical library in Palestine, and is much frequented by engineers, men of science, teachers and Government officials from all over the country. Unfortunately, the English section seems to be rather small, and a large number of scientific and technical books and journals published in England are lacking. This is not to be wondered at, as anyone will know who has tried to set up a new scientific library with little money. Jews go to Palestine mainly from the Continent, but are prepared to take up English as their second language to Hebrew and to come into more intimate contact with British thought. The library of the Hebrew Technical Institute at Haifa is therefore commended to the generosity of publishers and learned societies in Great Britain.

Cosmic Rays

A DISCUSSION meeting of the Royal Society was held on May 26 on "Cosmic Rays". The discussion was opened by Prof. P. M. S. Blackett, and papers were read by Profs. P. Auger (Paris), E. Regener (Stuttgart), and J. Clay (Amsterdam). After some further specific contributions from workers in Great Britain, a general discussion followed.

It is now generally agreed that cosmic radiation, as observed at the earth's surface, consists of two components distinguished empirically by their different rates of absorption. The 'soft' component, which constitutes about 20 per cent of the total cosmic ray intensity at sea-level and is practically all absorbed at a depth of 10 m. of water below sea-level, is now believed to consist of high-energy electrons which obey Dirac's relativistic theory. The application of this theory to the emission of radiation by such electrons in nuclear collisions, and to the production of electron pairs by radiation, has in fact provided in a remarkably unforced manner a satisfactory explanation of the absorption of the soft component and the phenomenon of electron-showers which accompanies its passage through matter.

The hard or penetrating component, on which most of the discussion was centred, is of considerable interest in that it is now supposed to consist of particles of a 'new' type, possessing electronic charge but a mass greater than that of an electron and less than that of a proton, provisionally referred to as 'heavy' electrons.* This interpretation of the hard component was suggested about a year ago by Neddermeyer and Anderson on rather circumstantial grounds, but more direct evidence has since been obtained for the existence of such a particle in cosmic rays. This evidence comes from the observation, in a Wilson cloud-chamber, of tracks the ionization and curvature (in a magnetic field) of which are not consistent with electrons or protons, but indicate a particle with electronic charge and a mass about 200 times that of an electron (that is, about one tenth protonic mass).

Examples of such tracks obtained by different workers were shown during the meeting. The comparative rarity of these anomalous tracks may be attributed to the small distance the particles travel after their velocity has fallen sufficiently low to give

* That the hard and soft components consist of different kinds of particles, rather than particles all of the same kind but of different energies, was clearly put forward by Auger in 1935 (Nature, 135, 820; 1935). Auger's description of the soft component is almost identical with our present view, and for the hard component he suggested "heavy particles such as protons".

tracks with an ionization clearly distinguishable from that along tracks of the same curvature produced by electrons or protons.

In his opening address, Prof. Blackett set forth the 'birth, life and death' of the heavy electron as the main problems now awaiting solution. Prof. P. Auger described recent experiments which contribute to an understanding of the manner of their creation. In these experiments the frequency of coincident discharges of a number of counters of high resolving power (*c.* 10^{-6} sec.) is observed. The results obtained indicate the existence (in the open) of showers spread over at least 25 sq. m. and containing at least 1,000 particles. The observation of crucial interest, however, is that the particles in these showers have a range of about 15 cm. of lead. This means that the particles are of the penetrating type, that is, heavy electrons. It seems, therefore, that a whole shower of heavy electrons may be created in one act, and the experiments are consistent with the view that the heavy electrons are secondary in origin.

The heavy electrons are penetrating because, owing to their large mass, very little radiation is emitted in nuclear collisions, this emission of radiation being the process which stops high-energy electrons and gives rise to the ordinary 'cascade' showers. However, though the energy lost by the penetrating particles in traversing matter is very much less than that lost by electrons, it is yet appreciably greater than the theoretical energy loss by particles of 200 electron masses. The latter is mainly due to collisions with atomic electrons, with a small contribution from collisions with atomic nuclei. Prof. P. Auger reported measurements carried out in collaboration with P. Ehrenfrest according to which the actual loss is more than three times the theoretical value. The experiments of Blackett and Wilson require a still higher ratio. This discrepancy is of much interest and its further investigation may throw light on the properties of the new particle.

The ultimate fate of the heavy electrons is not yet clear. Comparatively few are observed with energies less than about 2×10^8 volts, suggesting their disappearance or transformation into electrons at this energy (Blackett). However, in this region the velocity of the heavy electron starts to fall appreciably below that of light, and the attendant rapid increase in ionization would in any case reduce the relative number of heavy electrons with energy much below 2×10^8 volts. No definite conclusion regarding this matter can be drawn from existing observations.

The heavy electron is not unwelcome to theoretical physicists. Such a particle was in fact envisaged by Yukawa so long ago as 1935 in order to explain the force between a proton and a neutron. Previous attempts to explain this force on the basis of electron exchange and Fermi's theory of β-decay gave results of a wrong order of magnitude. Yukawa assumed that the role of exchange was taken by a new type of particle and showed that to explain the observed force the new particle would have to be given a mass of about 200 electron masses—in remarkable agreement with the particle now found in cosmic radiation. Thus, in much the same way as the positive electron in cosmic rays bore out the predictions of Dirac's theory of negative energy states, the heavy electron bears out the crucial assumption in Yukawa's theory of nuclear forces. This theoretical aspect of the subject was dealt with by Dr. W. Heitler and Dr. H. J. Bhabha. Dr. Heitler showed how the original theory of Yukawa had to be modified to give the right dependence of the forces between a neutron and a proton on the orientation of their spins, and also showed that the mass attributed to the new particle to explain the forces also corresponds to the departures of the magnetic moments of a neutron and proton from the values required by Dirac's theory for elementary particles. Dr. Bhabha discussed the applications of the theory in the creation and behaviour of the heavy electrons in cosmic rays. In reply to a question, Sir Arthur Eddington stated that while the 'background' particle of his recent theory might be made to play the part in nuclear forces similar to that assumed in Yukawa's theory, he would not expect it to be able to exist in the free state as, for example, a cosmic ray particle.

Matters concerning the effect of the earth's magnetic field were discussed by Prof. J. Clay and Dr. E. G. Dymond. Prof. Clay finds that the line of minimum cosmic ray intensity, though always close to the magnetic equator, shows definite departures from it, and the significance of this was discussed. Another effect reported by Prof. Clay was a decrease in the intensity of the soft component of cosmic rays during a magnetic storm, indicating a disturbing current of about 10^7 amperes at two to four earth radii away. Dr. Dymond gave an account of his experiments made in collaboration with Dr. Carmichael on the variation of cosmic ray intensity with altitude in the region of the north magnetic pole (see also NATURE, **141**, 910; 1938). The agreement of the results with those of Regener in lower latitudes (49°) indicates a lower limit of about 3×10^9 volts to the energy of the cosmic ray particles in this region of the solar system. The suggestion that this cut-off is due to the sun's magnetic field is unacceptable if recent estimates of its magnetic moment are reliable. The cut-off would accordingly refer to the cosmic rays in outer space, and its cause is not yet understood.

Prof. Regener described experiments on the variation with time of the hard component. Periodic variations both with respect to solar and sidereal time are found. The former has an amplitude of 0·25 per cent, with maxima at 10^h and 22^h. The variation with sidereal time has a smaller amplitude with a maximum at about 18^h, and may be attributed to the effect of galactic motion suggested in this connexion by Compton.

While there is obviously much to be cleared up in the field of cosmic rays, the discussion left the impression that the subject is not as much in a state of confusion as it has often been in the past.

E. J. WILLIAMS.

Obituary Notices

Prof. W. Stroud

PROF. WILLIAM STROUD, chairman of the firm of Barr and Stroud, Ltd., died at the age of seventy-nine years on May 27, at Torquay.

At an unusually early age young William Stroud of Bristol entered Balliol College, Oxford. "I was confronted," he wrote, "with the problem whether I should study Latin Hexameters and Greek Iambics or devote myself to what was contemptuously called 'Stinks'." It was a lecture by Prof. Tyndall that determined his choice, and his association with the late Prof. Barr that diverted his physics to industry.

When in July, 1936, the University of Leeds bestowed upon Lord Rutherford and himself the honorary degree of D.Sc., he wrote: "There was Lord Rutherford, the most worthy representative of Pure and Sacred Physics, and here was I, the least worthy representative of Profane Physics," between which and engineering he found it difficult to discriminate, for he was both a physicist and an engineer. How to attain some superlative accuracy from available materials and machines was a question never absent from his mind. For judicious approximation—that characteristic of the skilled engineer—he had a natural gift, but he never acquired the facility in the use of the slide rule of his colleague who, he alleged, in order to multiply two by two, would set these figures on the appropriate scales and, after close scrutiny, declare the product to be 3·96 or 7.

From Balliol, Stroud proceeded to the Universities of Heidelberg and Würtzberg, where, incidentally, he acquired his habit of continuous smoking. Arthur Smithells in the Heidelberger Schloss dared him to smoke a five-pfennig cigar. The results of this unaccustomed experiment were unpleasant. "I determined," he said, "to conquer such squeamishness and eventually achieved such a triumph that up to date I must have smoked over 110,000 cigars—more than half a ton of tobacco—with much satisfaction, and three cigarettes smoked simultaneously in parallel with no satisfaction whatever."

Soon after Stroud's return to England, the Yorkshire College of Leeds in June 1885 lost, by resignation, two of its professors, Sir Edward Thorpe and Sir Arthur Rücker. His friend, Prof. Smithells, was appointed to the vacant chair of chemistry and he, at the early age of twenty-five years, succeeded Sir Arthur Rücker as Cavendish professor of physics. This chair he occupied with great distinction until 1909, when he retired in order to devote his whole attention to the rapidly expanding business he and his partner had established in Glasgow.

During his first session, Stroud thought it necessary to discourse with what he termed "the best Professional dignity he could summon to his assistance". From the results of the terminal examinations he was, however, dismayed to find "that most of the students had learned next to nothing from my lectures". "I resolved," he said, "that the Pontifical Pomposity to which I had been accustomed would be a thing of the past." How well he succeeded in teaching physics effectively with inspiring geniality will always be remembered by his many students, to whom he was affectionately known as 'Billy'.

It was at the Yorkshire College that he met the colleague of his lifetime, the late Archibald Barr, the occupant of the chair of engineering at Leeds and later at Glasgow. Their collaboration in the invention of the rangefinder and many other valuable appliances has already been recorded in the obituary of Prof. Barr (NATURE, 128, 294; 1931) and is well known. The power of assessing conditions and of rapid readjustment was an outstanding characteristic of Prof. Stroud in all his activities, whether physical, practical or financial, for in all these spheres he was eminently successful. For any problem his penetrating mind would produce not merely one but several solutions and each with its variations. His letters from Leeds abound with coloured sketches of diagrams and mechanisms and such expressions as "Undoubtedly this is the way to do it.—A still better way is this—". "Try turning the mechanism inside out." Gifted with eloquence, he was sparing of unnecessary words. Invariably his letters ended with "Y.v.t., W.S."

By his death, science and industry have lost a very great man. JAMES WEIR FRENCH.

Dr. C. C. Edgar

WE regret to record the sudden death of Dr. Campbell Cowan Edgar, distinguished as an authority in Egyptian archæology, which took place on May 10 at Berkhamsted.

Dr. Edgar, who was of Scottish extraction, entered Oriel College as a scholar in 1891, and later was attached to the Egyptian Department of Antiquities, where he became acting head of the Musée des Antiquités in Cairo. He contributed a large number of articles to the "Catalogue Général des Antiquités Egyptiennes du Musée du Caire", dealing with the development of various aspects of Greek art and culture, more especially under the influence of its Egyptian environment. By these studies he came to be recognized as one of the first authorities on the culture of Græco-Roman Egypt. His knowledge and reputation marked him out as well fitted, notwithstanding his lack of specialized training, to undertake the editing of the Zenon archive, an extensive collection of papyri found at Darb-el-Gerza (Philadelphia) in the Fayum, which had been acquired from time to time by the Cairo Museum. A selection published in the "Annales du Service" was speedily and widely accepted as authoritative, and fully justified his selection for the task. This verdict was confirmed by the four volumes afterwards published by him in the "Catalogue Général". Detailed knowledge of the second Ptolemy's scheme of land development in the Fayum is largely due to Edgar's commentary.

On his retirement, Edgar continued his papyrological work and was associated with the late Dr. A. S. Hunt in his work on the Tebtunis papyri. He had also undertaken the editing of the portions of the Zenon papyri in the possession of the University of Michigan and the Rylands Library, Manchester. He acted in an advisory capacity for Græco-Roman Egypt in the editing of the *Journal of Egyptian Archæology* and was a member of the committee of the Egypt Exploration Society. His services to papyrology and Egyptian archæology received the recognition of the honorary degree of Litt.D. from the University of Dublin.

WE regret to announce the following deaths:

Prof. W. A. Bone, F.R.S., formerly professor of chemical technology in the Imperial College of Science and Technology, on June 11, aged sixty-seven years.

Mr. B. D. Burtt, survey botanist in the Department of Tsetse Research, Tanganyika Territory, on June 8.

Mr. M. J. R. Dunstan, O.B.E., principal of the South-Eastern Agricultural College, Wye, in 1902–22, and of the Royal Agricultural College, Cirencester, in 1922–27, on May 28, aged seventy-four years.

Dr. W. W. Campbell, For. Mem. R.S., president of the University of California in 1923–30, director of the Lick Observatory in 1901–30, on June 14, aged seventy-six years.

Mr. A. W. Shorter, assistant keeper of the Department of Egyptian and Assyrian Antiquities in the British Museum, on May 31, aged thirty-two years.

Dr. Sinclair Smith, physicist at the Mount Wilson Observatory, on May 18, aged thirty-nine years.

Mr. C. F. M. Swynnerton, C.M.G., director of tsetse research in Tanganyika Territory, on June 8, aged sixty years.

News and Views

King's Birthday Honours List

THE list of Birthday Honours conferred by H.M. the King includes the names of the following men of science and others associated with scientific work: *Order of Merit:* Sir Arthur Eddington. *Baron:* Sir Josiah Stamp. *Baronets:* Major Sir William Prescott, chairman of the Metropolitan Water Board; Lieutenant-Colonel Sir Archibald Weigall, chairman of the Royal Empire Society. *G.C.M.G.:* Lord Harlech, lately Secretary of State for the Colonies. *K.C.B.:* Sir Cyril Hurcomb, chairman of the Electricity Commission. *K.B.E.:* Prof. T. H. Easterfield, formerly director of the Cawthron Institute of Scientific Research, New Zealand; Sir Samuel Hordern, president of the Royal Agricultural Society, New South Wales; Mr. A. W. Street, First Deputy Under-Secretary of State, Air Ministry, lately Second Secretary, Ministry of Agriculture and Fisheries. *Knights Bachelor:* Mr. W. G. Ball, surgeon and dean of the Medical College, St. Bartholomew's Hospital; Mr. W. A. Cosgrave, lately chief commissioner of the Andaman and Nicobar Islands; Dr. Cyril Norwood, president of St. John's College, Oxford; Mr. W. Roberts, manager of the British Cotton Growing Association Farm, Khanewal, Multan District, Punjab; Dr. R. B. Wade, president of the Medical Board, New South Wales.

C.B.: Dr. J. J. Fox, Government chemist. *C.M.G.:* Mr. G. A. Jones, commissioner of agriculture, Imperial College of Tropical Agriculture, Trinidad; Prof. A. E. V. Richardson, deputy chief executive officer, Council for Scientific and Industrial Research, Commonwealth of Australia; Mr. J. W. Spiller, chief engineer, Designs Branch, Crown Agents for the Colonies. *C.I.E.:* Lieutenant-Colonel E. H. V. Hodge, professor of medicine, Medical College, Calcutta, and first physician to the College Hospitals, Bengal; Mr. H. S. E. Stevens, secretary to the Government of Bengal in the Agriculture and Industries Department, Bengal; Mr. T. A. Whitehead, chief conservator of forests, Madras. *C.B.E.:* Mr. H. Bishop, assistant chief engineer, British Broadcasting Corporation; Mr. W. W. Henderson, director of veterinary services, Nigeria; Dr. Elizabeth Hurdon, lately director of medical services and research, Marie Curie Hospital, Hampstead; Prof. B. Melvill Jones, Francis Mond professor of aeronautical engineering, University of Cambridge; Mr. E. J.

Wayland, director of geological survey, Uganda; Mr. E. B. Wedmore, director and secretary, British Electrical and Allied Industries Research Association.

O.B.E.: Dr. N. Ahmad, director of the Technological Laboratory, Matunga, Bombay; Lieutenant-Colonel Ambuj Nath Bose, professor of pathology, Prince of Wales' Medical College, Patna, Bihar; Dr. G. Bryce, assistant director of agriculture, Nigeria; Mr. J. W. Cassels, director of agriculture, County Durham; Dr. S. E. Chandler, principal of the Plant and Animal Products Department, Imperial Institute; Mr. P. M. Cooper, chairman of Water Commission, Jamaica; Mr. H. M. Gardner, conservator of forests, Kenya; Prof. R. M. Gordon, director of Sir A. L. Jones Research Laboratory, Freetown, Sierra Leone; Mr. A. P. F. Hamilton, deputy conservator of forests, Hoshiarpur Siwaliks, Punjab; Dr. R. B. Jackson, malariologist, Medical Department, Hong-Kong; Mr. A. R. Lambert, inspector, Plant Observation Section, Gezira Agricultural Research Service, Sudan Government; Mr. H. G. Mundy, secretary, Department of Agriculture and Lands, Southern Rhodesia; Mr. R. O'F. Oakley, principal, Department of Scientific and Industrial Research; Mr. D. Robinson, superintending examiner, Patent Office, Board of Trade; Captain J. C. A. Roseveare, chief drainage engineer, Ministry of Agriculture and Fisheries; Mr. B. S. Smith, superintending scientist, Anti-Submarine Establishment, Portland; Dr. A. W. Turner, senior bacteriologist, Animal Health Division, Council for Scientific and Industrial Research, Commonwealth of Australia; Mr. A. E. White, principal of Shrewsbury Technical College; Mr. D. W. Young, deputy surveyor of the New Forest, Forestry Commission. *M.B.E.*: M. R. Ry. Krishnaswami Ayyar Ramayya Avargal, paddy specialist at the Agricultural College and Research Institute, Coimbatore, Madras; Mr. H. L. Dutta, deputy director of agriculture, Orissa; Mr. W. G. Leckie, senior agricultural officer, Kenya; Dr. S. K. Mitra, professor of physics, University of Calcutta; Mr. C. H. Norton, district commissioner, British Guiana; Mr. V. P. Sondhi, geologist, Geological Survey of India. *I.S.O.*: Mr. F. Jenner, district commissioner, Basutoland; Mr. A. Percival, surveyor-general and chief property officer, Department of the Interior, Commonwealth of Australia; Mr. A. H. D. le P. Trench, senior coffee officer, Kenya.

Sir Arthur Eddington, O.M., F.R.S.

THE appointment of Sir Arthur Eddington by His Majesty the King to the Order of Merit will be warmly acclaimed by scientific workers in every corner of the globe as a fitting reward for a series of remarkable achievements in the realms of astronomy and theoretical physics. Senior wrangler and fellow of Trinity College, Cambridge, Eddington entered the scientific world, as chief assistant at the Royal Observatory, Greenwich, at the beginning of a new epoch in astronomy; Kapteyn had made his discovery of star-streaming in 1904 and within a few months Eddington contributed his first important investigation on this subject, to be followed in 1910 by his classic treatment of the proper motions of the naked-eye stars. In 1913, Eddington succeeded Sir George Darwin in the Plumian chair of astronomy at Cambridge, and in 1914 he was appointed director of the Cambridge Observatory in succession to Sir Robert Ball. Between 1913 and 1915, Eddington published several outstanding papers on the dynamics of stellar systems, which are still unsurpassed as models of mathematical elegance and astronomical insight. Relativity and the internal constitution of the stars next, and almost simultaneously, claimed his attention. In the former subject he is recognized, next to Einstein himself, as the foremost authority and investigator. The latter subject is of his own creation and has attracted many of the most eminent astronomers to a fruitful field of research. Within recent years, Eddington's researches have been devoted to the theory of the expansion of the universe and to the interrelation of quantum mechanics and relativity. Eddington's scientific influence is world-wide; his mathematical books are standard works; his popular books have brought delight and understanding to innumerable readers, scientific workers and laymen alike, and have influenced in a remarkable way the currents of recent philosophical thought.

Prof. E. S. Goodrich, F.R.S.

ON June 21, Prof. E. S. Goodrich celebrates his seventieth birthday, in honour of which he is being presented with a volume of "Essays on Evolution" by his colleagues and pupils. Starting his career at University College, London, he followed Sir Ray Lankester to Oxford in 1891, where he has occupied the Linacre chair of zoology and comparative anatomy since 1921. His contributions to zoology, and especially to morphology, are too well known to require detailed enumeration here. Mention should, however, be made of his classical researches on the nephridia and genital ducts, the Stonesfield mammals, the auditory ossicles, the segmentation of the vertebrate head, his general work on the structure and development of vertebrates, and his interpretative studies of the problems of homology, heredity, development and evolution. It is to be noted further that by his work and his teaching he has preserved and encouraged interest in the problem of form, which, now that experimental methods are available for biological studies, is more essential than ever as a starting-point and an objective for research in the newest branches of biology. We offer Prof. Goodrich our most sincere congratulations.

Prof. Irvine Masson, M.B.E.

As announced elsewhere in this issue (p. 1112) Prof. Irvine Masson has been elected to the office of vice-chancellor of the University of Sheffield, which is about to become vacant owing to the retirement of Dr. A. W. Pickard-Cambridge. Prof. Masson was born in 1887, the son of the late Sir David Orme Masson, vice-chancellor of the University of Melbourne, and grandson of Prof. David Masson, the well-known professor of English at Edinburgh. He has been professor of chemistry and head of the Department of Pure Science in the University of Durham since 1924. He was educated at Melbourne

Grammar School, the University of Melbourne, the University of Edinburgh, and the University of London, and is a doctor of science of the University of Melbourne. He was lecturer and reader in chemistry at University College, London, before and after the Great War, while in 1915–19 he was at the Research Department, Royal Arsenal, Woolwich. From 1921 until 1924 Prof. Masson was secretary of the Chemical Society, and he was a member of the Senate of the University of Durham in 1930–36. He is a member of the Council of the Institute of Chemistry and of the Council of the Universities' Bureau. He gave the Alexander Pedler Lecture of the British Science Guild in 1931, when he spoke on "Problems in the National Teaching of Science". His published work includes "Three Centuries of Chemistry" (1925), papers on physical, inorganic and organic chemistry in the journals of the Royal Society, Chemical Society, etc., and occasional bibliographical studies in the *Transactions of the Bibliographical Society*.

Earthquake of June 11

AT 11.58 a.m. (G.M.T.) on June 11, an earthquake of unusual severity was felt all over Belgium and Holland, in the south-west of Germany, the north-east of France and the south-east of England. From the early accounts, the intensity of the shock seems to have been greatest in the west of Belgium, where buildings were slightly damaged, several persons were injured and one was killed. In France, it was most severe in the district around Lille, where many chimneys were thrown down, and at Roubaix, close to the Belgian frontier, where about twenty persons were injured. It was felt also at Boulogne and Paris and, it is said, at Strasbourg. It was observed all over Holland, though but slightly in the north and east of that country. In the south-east of England, especially in Kent, the earthquake was felt rather strongly and also at places so far from the origin as London, Ipswich and Brighton. The disturbed area must therefore have been at least 380 miles long from east to west and 330 miles wide, and have contained not less than 100,000 square miles. It is difficult at present to assign the position of the epicentre. It may have been under the North Sea near the coast of Belgium, or on land in the west of that country. The earthquake was clearly of less intensity than that of April 6, 1580, but, though many of the places disturbed by both shocks are the same, its epicentre must have lain some distance to the east of that of the earlier earthquake, which, as Mr. E. R. Ockenden has shown (NATURE, 138, 472; 1936) was probably submarine and near the east coast of Kent.

Commemorative Window at the Old Ashmolean, Oxford

ON June 11, in the Museum of the History of Science, Oxford, the new window commemorating the gifts of the Mercers', Grocers' and Merchant Taylors' Companies, the Royal College of Physicians and of the Friends of the Old Ashmolean, was unveiled by the Vice-Chancellor in presence of a large and representative audience. Before the unveiling, speeches were made in the Divinity School by Sir Cecil Clementi, Sir Henry Norbury, Dr. R. Hutchison and Dr. G. D. Parkes and also by the Vice-Chancellor. The new window is placed at the bottom of the staircase of the Museum next to a similar window unveiled by Lord Birkenhead about nine years ago. At the top is represented the arms of Dr. R. T. Gunther, the present keeper and virtual founder of the Museum as it has now become. Below this are represented the arms and crests of the City Companies mentioned and the arms of the Royal College of Physicians.

Meyerstein Institute of Radio-Therapy

THE Meyerstein Institute of Radio-Therapy at the Middlesex Hospital, London, was opened by Sir William Bragg on June 9, before a large audience with many representatives of medicine and science. Sir William Bragg referred in reminiscent terms to the early days of X-rays and radioactivity, pointing out the ever-growing interest in the quest of the invisible phenomena about us. The Institute which he declared open is at the north end of the original Cancer Wing of the Hospital, four floors of which have been reconstructed and adapted to radiological work. The main equipment consists of four X-ray installations having Metropolitan-Vickers tubes actuated at 250 kilovolts, four Newton and Wright sets of oil-cooled Siemens tubes to be run at 200 kilovolts, and a 4-gram radium unit, the radium being automatically transferred to a large radium safe surrounded by 10 inches of lead when not in actual use upon patients. The protection of the personnel has been carefully studied throughout the entire working arrangements. The layout of the Institute is of a very pleasing as well as efficient character, being well ventilated and lighted, with ample space and air for patient and operator alike. The whole policy has been to provide trustworthy apparatus with the best possible conditions under which a selected staff can pursue radiological investigation.

East Malling Research Station

THE purchase by East Malling Research Station of the adjoining property of Bradbourne will provide a background of more than ordinary interest for the future activities of the Station. Originally a moated Tudor house built around an open courtyard, Bradbourne was transformed in the early eighteenth century into a typical Queen Anne mansion. From the Station's point of view, the estate of 200 acres is an even more important acquisition than the house itself, providing opportunity for future development of field experiments under conditions which are typical of much of the fruit-growing land in Kent. The open ground in the district has already been largely built over, and had Bradbourne been allowed to suffer a similar fate, the expansion of research activities of the Station in future years might have been seriously hampered. The prompt action taken by the committee in securing the estate when it came into the market has met with encouragement and support from the Government and from several important public bodies including the National Trust, the Council for the Preservation of Rural England, the Pilgrim Trust, and the Society for the Protection of Ancient Buildings. An enterprise of this nature which will mean at one and the same time the safeguarding of land for the development of scientific research and the preservation of a green belt in an area rapidly becoming industrialized, should have a double appeal: to those who think well of East Malling as a research centre, and to those also who approve of keeping part at least of the 'Garden of England' unspoilt. Such a project as the purchase and maintenance of Bradbourne must necessarily entail a heavy strain on the Station, and it may be several years before it is free from financial anxiety. Hence any contributions towards paying off the debt for the purchase and restoration will be welcomed by the Director, East Malling Research Station, Near Maidstone, Kent.

B.M.A. Committee on Mental Health

THE ever-recurring problems of sickness both in industry and in the general population which cannot be satisfactorily diagnosed or relieved by reference to the bodily symptoms alone, has led to a slowly developing interest into the mental aspect of disease. More than ten years ago, a report of the Industrial Health Research Board gave experimental evidence that led to the view that telegraphists' cramp was a psycho-neurotic manifestation. Studies of industrial sickness-absence show that much inefficiency, lost time and unhappiness are related to disorders of the type vaguely labelled nervous breakdown. Also investigations into industrial failures show that a large proportion are people whose disabilities are of a mental or emotional nature. It is therefore opportune that a special committee of the British Medical Association should be appointed to study the problem of mental health in general. The committee is to make a thorough study of all the available statistics and will seek to compare the importance of mental illness with other conditions already recognized by the State as requiring action. It will consider the part which the general practitioner, hospitals, clinics under the Mental Treatment Act, child guidance and other clinics, can play in the prevention of such illness, and study the degree of success attainable by the present available methods of treatment. A very important part of the committee's work will be to consider the part allotted to psychological medicine in medical training. The members of the committee are as follows: Sir Robert Johnston (president), Sir Kaye le Fleming (chairman of council), Mr. H. Guy Dain (chairman of representative body), Mr. N. Bishop Harman (treasurer), Sir Henry Brackenbury, Dr. J. A. Brown, Dr. Millais Culpin, Dr. R. G. Gordon, Sir Walter Langdon-Brown, Dr. Mary C. Luff, Dr. E. Mapother, Dr. Doris M. Odlum, Dr. A. A. W. Petrie, Dr. J. R. Rees, Dr. Benjamin Reid, Dr. D. Stewart, and Dr. R. M. Stewart.

Bureau of Human Heredity

AN appeal for funds on behalf of the Bureau of Human Heredity, which appears in *The Times* of June 7, gives some slight indication of the value of the work which has been carried out by this organization with the limited resources at its disposal and in the brief period since its foundation. The function of the Bureau is to centralize in one organization as a world clearing-house the information already accurately ascertained on the inborn constitutional factors in man, and to distribute it freely wherever it is required. In less than eighteen months the Bureau has accumulated data on the inheritance of more than six hundred physical and mental differences. As a result of a financial appeal in May 1936, the Bureau secured sufficient support to enable it to carry on from day to day, while a grant for one year was made by a scientific worker. The present appeal is headed by Lord Dawson of Penn, with the support of Sir F. Gowland Hopkins, Sir E. Farquhar Buzzard, Sir Richard Gregory and others. In their view, the facts warrant an appeal to the public for a sum of £25,000, an amount which is not considered excessive in view of the importance of the work to be carried on. It would enable the activities of the Bureau to be placed on a permanent basis. In justification, the signatories to the appeal point out that attempts to improve the lot of the individual must remain largely ineffective so long as the data which reveal his inborn nature remain obscure. When the Bureau has been placed in a position to carry out its functions normally in accordance with the intentions of its promoters, it will be possible for any medical man to obtain in English the latest information from any country relating to, for example, the resistance or non-resistance of certain types to common infections, or occupational disease. Research workers themselves are well aware that the organization of knowledge, such as that upon which the Bureau is engaged, is little less important for scientific progress than research itself. Without it there is risk that much valuable work may suffer oblivion. The appeal is issued from the Bureau of Human Heredity, 115 Gower Street, London, W.C.1.

Haslemere Educational Museum

THE Haslemere Educational Museum will celebrate, on June 29, the fiftieth anniversary of its foundation. The speakers on the occasion will be Earl Winterton and Dr. John Ramsbottom. This museum was founded in 1888 by Sir Jonathan Hutchinson, F.R.S., at a time when the majority of the smaller museums were stagnant and uninspiring because they lacked teachers. Hutchinson was a great teacher, and through his teaching the museum at his country house at Inval, about a mile from Haslemere, quickly made its influence felt. There he arranged for the first time the space-for-time schedules of geology and human history which are still a special feature of the museum, and these schedules were largely used in his lectures to friends and to members of the Haslemere Natural History Society. In less than ten years the Museum had completely outgrown itself, and Hutchinson then built a much more commodious one in Haslemere on the hillside to the south-east of the town, and there continued to lecture at week-ends in the summer months.

In 1897, Mr. E. W. Swanton became curator of the Museum and still holds that office. The founder died in 1913; no provision had been made for its future, and it was taken over by a committee with Sir Archibald Geikie as chairman. From that time to the present, the necessary funds to allow the work to continue have been subscribed year by year chiefly by local residents. As its activities steadily increased, it became more and more desirable that the Museum should be moved to a central position. In 1925 the committee purchased an old house with beautiful grounds in Haslemere High Street; new galleries for the adequate display of the space-for-time schedules were added and the collections removed there in 1926. Afterwards a new gallery was added to contain a valuable gift of British birds. Through grants from the Carnegie United Kingdom Trust, the work has been extended to include a regional and ecological survey of the district. The value of the Museum as a teaching centre is widely known. Every autumn mycology students from the University of Oxford make it their headquarters. A course in field biology held at Whitsun attracted students from a wide area.

Hittites in Northern Syria

ONCE more Sir Leonard Woolley's archæological investigations in the East have produced unanticipated results. In his dispatch from Atchana in Northern Syria (*The Times*, June 13), which covers the work of his expedition during the first half of the current season, he records that two hundred inscribed tablets have been found, which reveal for the first time the existence of a strongly established and highly organized Hittite power in Northern Syria at about 1600 B.C., at least two centuries before the great expansion of the Hittite Empire, centring on Hattusas (Boghaz Keui) beyond the Taurus, in what is now Anatolia, with which scholars were previously familiar from excavation and inscribed records. These archives are part of the official documents removed from the Hittite palace, of which a preliminary examination was made at the close of last year's excavations, and now shown to have been destroyed by fire, presumably accidental, as the contents of the building had been removed. The most striking feature of the building, in the account given by Sir Leonard, is the skilled arrangement and the elaborate character of the accommodation. The ruins, still standing to more than a man's height, cover more than 22,000 square feet. Access to the building is from an open courtyard and through a great entry into an entrance hall, from which doorways right and left give admission to the business and residential quarters of the palace respectively. These were virtually separate buildings without intercommunication, and the difference in their character and arrangement indicate their entirely different purposes. In the residential quarter, intended, Sir Leonard thinks, for important members of the palace personnel—the royal family being accommodated above, and the domestic staff, equipment and stores being housed in the courtyard in front of the entry—the accommodation consisted of suites, each of which contained a good-sized bathroom and lavatory. The whole arrangement and content of the palace is, as Sir Leonard remarks, eloquent of a strong and stable government; while the pottery, ivory and gold work bear witness to relations with Cyprus, Crete, Phenicia and the Greek mainland, as well as with Egypt and Mesopotamia.

The Unity Schools

THE fifteenth Unity School was held at Jordans Hostel in Bucks, on May 20–23. The general subject was the need and the relation of philosophy to the social sciences, and an introductory address on that topic was given by Prof. Morris Ginsberg, on the evening of May 20. On May 21, Mr. F. S. Marvin introduced the central subject of "What we mean by Social Justice", and the liveliness of the discussion showed clearly how deeply the current thinking on these questions goes, and how much it needs clarification and, so far as possible, harmonization. Dr. C. H. Desch introduced the question of the comparison of our approach to truth in physical and social science, and Prof. Herbert Dingle gave a parallel statement. In particular the question was raised, and viewed from several angles, of whether it is possible in social science properly to speak of a scientific experiment. On May 22, Prof. J. H. Muirhead gave a carefully prepared and moving discourse on the place of the State in relation to right and justice, with the title, "State Law and Individual Morality". The programme, as originally drawn up, was concluded on the Sunday evening by a historical review by Dr. A. J. Carlyle of the various larger subjects which had occurred in the earlier debates—justice, law, sovereignty and the freedom and equality of men—mainly as they are treated in the codes and writings of Greeks, Roman jurists and medieval thinkers. In view of the great success and obvious usefulness of such gatherings, the possibility of extending them to a larger number of people, more frequent occasions and a still wider expanse of subjects is being considered. Further information on the Unity Schools can be obtained from Mr. F. S. Marvin, Pantiles, Coneydale, Welwyn Garden City, Herts.

Correct Street Lighting

THE General Electric Co. Ltd. has installed in its street-lighting showrooms at Magnet House, Kingsway, London, W.C.2, a model demonstrating many of the problems that arise in street lighting and how they have been effectively solved by the methods recommended in the final report on street lighting issued by the Ministry of Transport. The model measures 5 ft. long by 2 ft. wide, the lighting columns and roads being to a scale of 1 in 380. Running the whole length of the model is a main arterial road lighted by columns which in practice would provide a mounting height to light source of 25 ft. for a main road (Group *A*). The thoroughfare is lighted by a staggered arrangement of units not more than 150 ft. apart. In every third position an auxiliary unit is centrally suspended, so that there can be adequate lighting down and across what would otherwise be a dark central section of the road. After a roundabout, there is a dual carriage way and it is emphasized how necessary it is to treat dual carriage ways as if they were two separate roads. When the dual road bends away in the country from the 'roundabout', the lighting points become closer on the outside of the bend. Cross-road lighting treatment is also shown in several places. Lights here are arranged just beyond the crossing on the left-hand side as the traffic proceeds ; then traffic moving at right angles and pedestrians preparing to cross the road become clearly visible. In addition, photographs are shown to illustrate the more important features demonstrated by the model and suggested in the recommendations. A fuller description of this model is given in the *Osram G.E.C. Bulletin* of May 1938.

Short-Circuit Testing Stations

ABOUT ten years ago it was found necessary to build short-circuit testing stations in order to find out the true rating for a large switch or current-breaker. In order to find out how a switch will break a large electric current at a low voltage or a current at a very high voltage, different methods have to be used and special large and expensive devices are necessary. It is very unsatisfactory to assign nominal ratings based on theoretical design considerations and experience gained by similar apparatus. The International Electrotechnical Commission has now published a specification for the short-circuit testing of circuit-breakers, and manufacturers have to issue a certificate with the apparatus stating that it has passed the required proving tests. Eight years ago Messrs. Reyrolle and Co. built the first short-circuit testing station at Hebburn-on-Tyne and since then, two more have been erected in Great Britain and others are being constructed or are under contemplation. According to the *Electrical Power Engineer* of December last, the certification of switches is not exclusively confined to those manufacturers who own testing stations in whole or in part. The facilities of all the British proving stations are open to other manufacturers for making tests. This entails a definite assurance from the testing stations of privacy in testing and secrecy of results of experiments making so much noise and requiring so large a space. All work is carried out on apparatus under a reference number, the manufacturer's name being omitted and also the designation of the apparatus. During testing all entrances to the station are locked. A separate office is provided for the use of customers wishing to discuss reports. Sometimes cinematograph films of the tests are shown at these offices.

Paris Academy of Sciences

THE "Annuaire" of the Paris Academy of Sciences has for some years past included a biographical index of past and present members and *correspondants* of the Academy. In this year's volume (Paris : Gauthier Villars, 1938), this index is considerably enlarged ; notes have been added indicating the subject or subjects in which each individual was particularly interested, and the list of names has been augmented by including the members of the older body, the Royal Academy of Sciences (1666–1795). A paper read by Prof. Alfred Lacroix, one of the permanent secretaries of the Academy, at the meeting held on January 4 last (*C.R.*, **206**, 23), explains the changes that have been made and describes briefly the various previous attempts to provide a complete statement of past and present members of the Academy. The archives of the Academy now have a separate file for each individual who has been connected with it, and every effort is being made, by searching national, parish and other records, to ensure that biographical details are correct. Further, by dint of most painstaking research, the documents relating to the proceedings of every meeting of the Academy, apart from biographical material, have been classified and they are now also arranged in files, one to each meeting from that of "6 nivôse an IV" (December 27, 1795). As regards meetings of the Royal Academy of Sciences, there are in the archives 109 large folio volumes of *Procès verbaux* prepared by the five successive permanent secretaries, J.-B. du Hamel, Fontenelle, Dortous de Mairan, Grandjean de Fouchy and Condorcet, which go back to the first meeting on December 22, 1666. The total number of men of science who have belonged to the Academy since 1666 is 2,071 (members, 992 ; *correspondants*, 1,079) ; it possesses nearly sixteen hundred autographs and about the same number of portraits.

Curtis's Botanical Magazine

A COMPLETE volume of this beautifully illustrated botanical periodical has recently been published in one cover (*Curtis's Botanical Magazine*, **147**. London : Bernard Quaritch, Ltd. 63*s*. net). This is to fill a gap in the series created by the non-appearance of a volume in 1921. At the end of 1920, publication of the *Magazine* ceased, and it seemed possible that the copyright would pass to an owner in the United States ; but in 1921, the Royal Horticultural Society was presented with the copyright through the generosity of subscribers. The gap thus created in the series has now been filled through the generosity of Mr. Reginald Cory, and the volume is dedicated in accordance with his wish to Sir Isaac Bayley Balfour, Sir David Prain and Sir Frederick Moore in recognition of their services to botany and horticulture. Fifty-seven plants are described and beautifully illustrated, including eleven species of *Rhododendron*, fifteen of *Primula* and four of *Gentiana*. Plants from all parts of the world are described in the *Magazine*; but in this volume Chinese plants take pride of place—thirty-eight species ; five South African species are described and the rest come from countries so far apart as Peru, Siberia, Japan and Tibet. The method familiar to all readers of this periodical is adopted. The history of each species, so far as it is known, is briefly given, and this is followed by a detailed description of morphology (especially floral) and distribution. The beautifully coloured illustrations of each plant described are, of course, the main feature of the volume. The authoritative nature of the text cannot be questioned. Here one notices such familiar contributors as O. Stapf (seventeen species alone and ten in collaboration either with

C. V. B. Marquand or with F. Ballard), J. M. Cowan (thirteen species), A. B. Rendle (five species), and others including J. Anthony, G. Taylor, W. B. Turrill and T. A. Sprague. The volume is edited by Dr. J. Ramsbottom and does credit to editor and contributors. The price may appear to be high, but the illustrations alone make it good value and a real acquisition to any botanical library.

Biological Effects of Ultra-Sound Waves

A SECTION of Messrs. Hermann's "Actualités Scientifiques et Industrielles" series of publications is being devoted to investigations of the effects of radiation on living organisms; it is under the charge of Prof. N. Marinesco, director of research in the Institute of Physico-chemical Biology, Paris. Two parts dealing with ultra-sound waves and their properties have already appeared: (1) "Proprietes piézo-chimiques, physiques et biophysiques des Ultra-sons. Technique des ondes élastique de haute fréquence", and (2) "Propriétés des Ultra-sons. Destruction des micro-organismes. Préparation des colloides à basses températures. Réactions explosives. Réactions photochimiques". Both are written by Prof. Marinesco. The first 56 pages and 5 plates (15 francs) describes the electro-elastic properties of quartz, the production of stationary waves in liquids, the intensity of the radiation, the pressure it exerts and the absorption it undergoes. The second, of 68 pages and 7 plates (18 francs), describes the effects of ultra-sound waves in sterilizing water and milk, in producing emulsions, in detonating explosives and in accelerating chemical reactions with special reference to those in photography. Many of the plates are reproductions of photographs taken by the author. Bibliographies are provided.

International Union against Cancer

THE Third International Cancer Congress under the auspices of the International Union against Cancer will be held in Atlantic City, New Jersey, on September 11–16, 1939. The president of the Congress is Prof. Francis Carter Wood, director of the Institute of Cancer Research of Columbia University; Dr. Donald S. Childs of Syracuse, New York, is the secretary-treasurer; and Dr. A. L. Loomis Bell of Long Island College Hospital, Brooklyn, New York, is in charge of transportation and exhibits. The proposed sections are as follows: general research; biophysics; genetics; general pathology of cancer; surgery of cancer; radiological diagnosis of cancer; radiotherapy of cancer; statistics; and education. Details concerning section chairmen, committees and other data will be announced later. Further information can be obtained from the Institute of Cancer Research, 1145 Amsterdam Avenue, New York, N.Y.

A Regional Survey Field Service Pocket-book

THE Le Play Society's well-known "Discovery" chart has been revised and enlarged and its subject-matter has been put into pocket-book form with blank leaves for maps and notes. In this form it is published under the title "Exploration" at 4*d.*, postage 1*d.* It directs attention to some hundreds of possible fields of local exploration grouped under the major headings: geology, rivers and water-supply, weather and climate, vegetation and open spaces, agriculture, zoology, archæology, history, communications, occupations, folk-lore, place-names, modern and changing conditions, camping and rambling. It is calculated to stimulate youthful zest for exploration and arouse and develop scientific curiosity. An ethical aim is provided by the following passage, appearing on the front page, reminiscent of the teaching of Patrick Geddes and Victor Branford: "If you learn to know your own place well, and in so doing learn to love it more, it will help you to understand and appreciate other places, and to sympathise with their problems". It should prove serviceable to scoutmasters and girl-guides as well as to others engaged in the teaching of local history, local geography and civics and in training for citizenship.

Colonial Service Appointments

THE following appointments and promotions have recently been made in the Colonial Service: R. O. Roberts, field geologist, Uganda; W. L. Stapleton, inspector of mines, Malaya; F. G. Bridges, inspector of plants and produce, Nigeria; M. J. Douglass, agricultural officer, Sierra Leone; J. Ford, entomologist, Tsetse Research Department, Tanganyika Territory; K. S. Hocking, secretary, Tsetse Research Department, Tanganyika Territory; A. R. Jones, meteorological assistant, Sierra Leone; A. G. Robertson, field officer, Tsetse Research Department, Tanganyika Territory; F. L. Vanderplank, field officer, Tsetse Research Department, Tanganyika Territory; E. F. Whiteside, field assistant, Tsetse Research Department, Tanganyika Territory; T. W. Brown (agricultural officer), botanist, Research Branch, Department of Agriculture, Malaya; B. G. A. Low (botanist, Research Branch, Department of Agriculture), agricultural officer, Field Branch, Malaya; F. B. Higgins (senior inspector of mines, Nigeria), senior inspector of mines, Gold Coast; H. H. Cobon (assistant superintendent of surveys), superintendent of surveys, Malaya; F. W. Abbott (laboratory assistant, Medical Department), laboratory assistant, Grade I, Medical Department, Gold Coast; P. A. Clearkin (formerly deputy director of Laboratory Service, Tanganyika Territory), bacteriologist and pathologist, British Guiana (temporary appointment); C. K. Robinson (agricultural assistant), agricultural superintendent, Saint Vincent; G. C. Stevenson (assistant botanist, British West Indies Central Sugar Cane Breeding Station, Barbados), botanist, Sugar Cane Research Station, Mauritius.

Shower of Bright Meteors

A REMARKABLE shower of fireballs is reported to have been seen in southern Sweden on May 27 between $18^{h}\ 20^{m}$ and $20^{h}\ 12^{m}$ U.T. About $18^{h}\ 40^{m}$, two specially bright fireballs, visible in full sunshine, appeared over Bornholm Island. The general direction was from west to east. Further details of these and other fireballs are requested by A. Corlin, Lund Observatory. It is hoped that sufficient data will be available later to enable the paths to be computed.

Curious Fading of Comet Gale

As announced in NATURE recently, Comet Gale was found on May 1 by Mr. L. E. Cunningham at Harvard, its magnitude being 10. An orbit and ephemeris were computed, and, knowing the distances of the object from the earth and sun, its magnitude on various dates was estimated. The remarkable thing is that its magnitude is considerably less than that predicted, as the following figures will show :

Date	Predicted Magnitude	Observed Magnitude
May 9	9·5	11
28	8·5	11
31	8·4	13

It is probable that some rapid internal changes, on which one can only speculate at the moment, are taking place in the comet.

Announcements

THE Albert Medal for 1938 of the Royal Society of Arts has been awarded to H.M. Queen Mary "in recognition of her Majesty's unremitting interest in arts and manufactures to the great benefit of British industry and commerce". Queen Mary has intimated her acceptance of the medal.

DR. F. W. HAYWOOD has been appointed chief metallurgist to Wild-Barfield Electric Furnaces, Ltd., to take charge of the new research department nearing completion. Dr. Haywood, who is at present engaged with Messrs. I.C.I. (Fertilizer and Synthetic Products), Ltd., at Billingham, will be commencing his duties later in the year.

GEH. REG. RAT HEINRICH KAYSER, emeritus professor of physics at Bonn, and Dr. Hans Horst Meyer, emeritus professor of pharmacology, pathology and biology at Vienna, celebrated their eighty-fifth birthday on March 16 and 17 respectively.

PROF. PAUL FOURMARIER, professor of physical geography in the University of Liège, has been elected a foreign correspondent of the Geological Society of London.

PROF. M. T. BOGERT, professor of organic chemistry in Columbia University, has been awarded the Priestley Gold Medal of the American Chemical Society. The medal, the highest American honour in chemistry, is granted once in three years. It was established in honour of Joseph Priestley. Priestley lived most of his life in England but went to America late in life to escape hostility to his views as a nonconformist preacher. He lived in Philadelphia and Northumberland, Pa. Alone, and in collaboration with his many students, Prof. Bogert is the author of more than four hundred papers in synthetic organic chemistry.

MR. J. REID MOIR will give the next Huxley Lecture of the Imperial College of Science and Technology on May 4, 1939, at 5.30 p.m. The subject of his lecture will be "The Earliest Men".

THE tenth International Medical Congress for Psychiatry will be held at Oxford on July 29–August 2. A detailed programme will be published later. Further information can be obtained from Dr. E. B. Strauss, 81 Harley Street, London, W.1.

A NATIONAL conference on Maternity and Child Welfare will be held in the Great Hall, University of Bristol, on July 5–7, under the presidency of Mr. R. H. Bernays, M.P., Parliamentary Secretary of the Ministry of Health. Further information can be obtained from the Honorary Secretary, Dr. Minett, Carnegie House, 47 Piccadilly, W.1.

THE next meeting of the French Association for the Advancement of Science will be held at Arcachon on September 22–27 under the presidency of M. Guilliermond, member of the Institut de France and professor in the Paris Faculty of Sciences. The subjects for discussion are : (1) the oyster (palæontology, zoology, biology, hygiene, fishing and cultivation) ; (2) the marine pine and its derivatives ; (3) the pigments of living beings (chemical composition and psychological role) (4) biology and protection of fresh water. Further information can be obtained from the Secretary of the Association, 28 rue Serpente, Paris.

THE fifth International Locust Conference will be held in Brussels on August 25–September 1, under the patronage of His Majesty the King of the Belgians. The programme includes discussions on the standardization of studies on phase transformation in locusts ; on methods of studying locust migrations ; on general principles of anti-locust research, etc. The greater part of the programme is devoted to problems of organization of preventive control of locusts and grasshoppers in different natural regions of the world. Information on the Conference can be obtained from the Secretariat, 7 Place Royale, Brussels ; and from the Imperial Institute of Entomology, British Museum (Natural History), London, S.W.7.

WE have received the April issue of *Sands, Clays and Minerals*, a journal edited and produced by A. L. Curtis, Chatteris, which contains a number of interesting papers. One of these deals with the modern uses of tantalum and niobium, another with the reparation of historical buildings, and a third (by A. Barclay, of the Science Museum) is on early technical balances and is profusely illustrated. The journal is of a high standard and contains much information of scientific and economic interest.

ERRATUM. Prof. J. H. Orton writes that in his letter entitled "Life-History of the Salmon (*Salmo salar* L.)" in NATURE of June 4, p. 1017, the word "mature" in the bottom line of column 1 was inadvertently written for the word "immature".

Letters to the Editor

Packing Fractions of Bromine, Chromium, Nickel and Titanium

I HAVE obtained a new determination of the packing fraction of ^{79}Br by measurements of the doublet given by its triply charged atom and the quintuply charged atom of ^{132}Xe, the value for which has been provisionally given[1]. As the difference in mass between ^{79}Br and ^{81}Br has also been measured[2], values for both isotopes can be calculated as given below. These are provisional only, but are certainly more reliable than those previously in use. I hope in the future to get more accurate results by means of the doublet ^{81}Br+++ — C_2H_3, but this cannot be used now owing to the presence of aluminium in the discharge tube.

Very satisfactory results were obtained with chromium. The volatile carbonyl was used, which when combined with suitable proportions of methyl chloride gave ^{52}Cr — $CH_3{}^{37}Cl$ the doublet required. As soon as the initial difficulties of admitting the vapours in the right proportions had been overcome, a great many well-matched doublets were photographed giving very consistent measurements.

Experiments with nickel were disappointing. Nickel carbonyl was used, but the line ^{58}Ni++ could not be obtained intense enough for comparison with C_2H^5. As the first order line ^{58}Ni was strong, it was considered worth while to compare the ratio of this to CO_2 by means of the fairly near ratio ^{16}O to ^{12}C, using artificial doublets. Four complete sets of comparisons were made, and the mean of these indicates a negative packing fraction considerably smaller than that previously estimated ten years ago by the same method.

The packing fraction of ^{48}Ti has recently been given by Dempster as $- 7{\cdot}22 \pm 0{\cdot}1$ by direct comparison of its triply charged atom with the standard oxygen atom[3]. His comparisons of ^{48}Ti++++ — C were, however, not satisfactory. I have been to great pains to obtain and measure the corresponding doublet ^{48}Ti++ — C_2, as this affords an entirely independent check on the controversial value of ^{12}C. Titanium tetrabromide was used, but is very troublesome in the discharge. The line ^{48}Ti++ was very feeble and the exposures consequently long, and as there was little possible control on the relative intensities of the lines, only very few of the plates taken were of any value. After many weeks of work, seven reasonably well-matched doublets had been obtained with the mean result given below. If my value 2·96 for the packing fraction of carbon is used, the value obtained is virtually identical with Dempster's; conversely, this agreement provides a further independent and welcome confirmation of my value $12{\cdot}00355 \pm 0{\cdot}00015$ for the mass of ^{12}C. This and H = 1·00812 have been used in calculating these results:

Doublet	Number of doublets measured	Difference in packing fraction	Difference of mass
^{79}Br++ — ^{132}Xe+++++	6	$28{\cdot}30 \pm 0{\cdot}3$	0·0745
^{52}Cr — $CH_3{}^{37}Cl$	18	$9{\cdot}22 \pm 0{\cdot}15$	0·0479
^{48}Ti++ — $^{12}C_2$	7	$10{\cdot}20 \pm 0{\cdot}15$	0·0490

Symbol	Packing fraction	Isotopic weight
^{48}Ti	−7·24	$47{\cdot}9652 \pm 0{\cdot}0008$
^{52}Cr	−8·18	$51{\cdot}9575 \pm 0{\cdot}0008$
^{58}Ni	(−8·35)	$(57{\cdot}9516 \pm 0{\cdot}0020)$
^{79}Br	(−7·4)	$(78{\cdot}9417 \pm 0{\cdot}0020)$
^{81}Br	(−7·4)	$(80{\cdot}9400 \pm 0{\cdot}0020)$

Resonance in Nuclear Photo-Effects

IN connexion with the remarkable selectivity of nuclear photo-effects of heavy elements indicated by experiments, it was pointed out in a recent note in NATURE[1] that such photo-effects might provide a means of examining certain features of the mechanism of excitation of atomic nuclei not disclosed by ordinary experience about nuclear reactions by collisions. In fact, the probability of excitation of a nucleus by monochromatic radiation depends on the degree to which forced oscillations of given frequency of the nuclear matter can be produced, and experiments on the variation of the yield of the photo-effects with radiation frequency would therefore allow a direct estimate of the strength of coupling between the different modes of oscillation into which the collective motion of the nuclear particles may approximately be resolved.

In view of the very incomplete experimental evidence, I would like, however, to emphasize the preliminary character of any such estimates as attempted in the note referred to, and at the same time to direct attention to a possible misunderstanding of the argument regarding the separation of the course of the photo-effects into successive stages. Such a separation into the initial excitation of a certain mode of oscillation and its subsequent quenching due to the coupling cannot, of course, be carried out in the case of strictly monochromatic radiation. Nevertheless, a well-defined meaning can be attached to the argument as soon as we, instead, consider the effect of a time-limited irradiation with a corresponding frequency uncertainty.

In particular it follows from such a treatment that, so far as we are concerned only with mean values of the yield of the photo-effects over energy regions wide compared with the distance of the nuclear levels, all typical resonances will be essentially the same whether the level distribution is discrete or continuous. It follows also that, contrary to an assertion in the note, the selectivity is completely independent of the ratio between the chances of the re-emission of the whole energy as a single radiation quantum in the initial and in the subsequent stage of the excitation process. All such conclusions are in fact in complete harmony with a treatment on the lines of the ordinary theory of dispersion of monochromatic radiation, according to which the selective phenomena would be attributed to an abnormally large radiative transition probability to the normal state from certain energy regions.

For the clarification of these points I am indebted to discussions with Prof. Peierls and Prof. Placzek, in collaboration with whom a paper about nuclear resonance phenomena with special regard to the above-mentioned arguments is being prepared for publication in the communications of the Copenhagen Academy of Sciences.

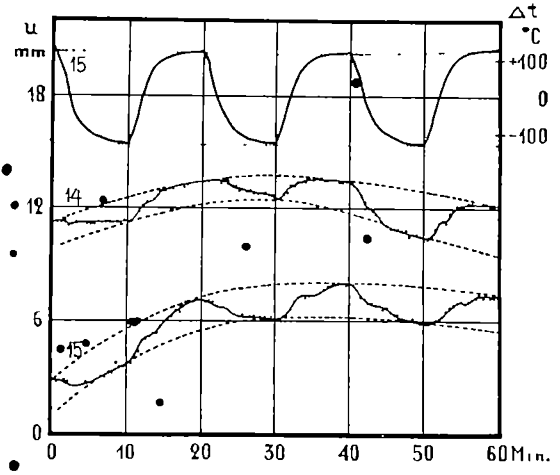
Effects of Gas Ions on the Benedicks Effects in Mercury

It has been proved by one of us[1] that a thermoelectric force of the first kind—now, with W. Meissner, called the first Benedicks effect—appears in asymmetrically heated homogeneous liquid mercury, with a *negative* sign. (A negative sign indicates that in the external circuit the electron current flows from the hot side of the temperature gradient to the cold one.) As for the reverse effect—the second Benedicks effect (or heat transport caused by an electric current)—it was found by us[2] that this effect likewise was 'negative' in pure mercury containing gas, but *positive* in degassed pure mercury—evidently due to a lowered content of gas ions, already known to influence the sign of this effect in the case of platinum[3]. The conclusion was drawn that likewise a change of the sign of the first Benedicks effect may be caused by a lowered gas content.

In order to test the accuracy of this conclusion, a 'strangulation vessel' of Normal-glass—giving locally a high temperature gradient—filled with carefully degassed mercury, was used. Possible sources of error were carefully considered. From eight series obtained in varying circumstances—all of them in good agreement—two are reproduced in the accompanying figure. The upper curve gives the temperature differences producing the gradient, the lower ones (two series) the corresponding galvanometer deflections (1 mm. = $1{\cdot}16 \times 10^{-9}$ volts). The reproducibility is seen to be fairly good. Most of the periods show an inflection point, due to the fact that the E.M.F. is proportional to the third degree of the temperature difference—this was separately proved.

The main result is, that *the first Benedicks effect in mercury of highest purity is actually a positive one.* The *negative* sign found earlier, consequently, *must be due to the action of gas ions*, as in the case of the second Benedicks effect.



This causes an earlier discrepancy of the periodic table to disappear: while, in its second column, zinc and cadmium have a positive Thomson effect, the following metal, mercury, has always been found to give a negative sign for the Thomson effect. For theoretical reasons, we may now conclude that the Thomson effect of pure mercury quite free from gas will be positive, causing this discrepancy to disappear.

Molecular 'Rejuvenation' of Muscle Tissue

The decomposition of creatine phosphoric acid during muscular action, and its rebuilding during rest, has been the subject of numerous detailed investigations. We were interested in the problem, if, and to what extent, creatine phosphoric acid molecules are decomposed and afterwards rebuilt, or 'rejuvenated', in the resting muscle. This problem can be easily solved by injecting labelled sodium phosphate, for example, into frogs, and determining if, and to what extent, creatine phosphoric acid extracted from the muscle of the frog becomes labelled (radioactive). Phosphorus atoms present in creatine phosphoric acid and other organic compounds do not exchange spontaneously with other phosphorus atoms present, and thus the fact that labelled creatine phosphoric acid can be isolated from the muscle is a proof that this was synthesized after the administration of labelled sodium phosphate.

The muscle was placed at once after removal in liquid air, the acid soluble components extracted with trichloracetic acid kept at − 9°, and the inorganic phosphate present in the solution precipitated as ammonium magnesium salt. The next step was the decomposition of creatine phosphoric acid remaining in the filtrate from the last-mentioned precipitate. The decomposition was carried out by adding[1] sulphuric acid (1*n*) and ammonium molybdate (1 per cent) to the solution. The phosphate ions were then precipitated as ammonium magnesium salt. The phosphorus content of the latter was determined by the colorimetric method of Fiske and Subbarow, and its radioactivity by making use of a Geiger counter. The results obtained for this and some other fractions are seen in the accompanying table.

PHOSPHORUS ISOLATED FROM FROG KILLED 3 HOURS AFTER SUBCUTANEOUS INJECTION OF LABELLED SODIUM PHOSPHATE.

	Relative specific activity (activity per mgm. P)	
	Frog kept at 2°	Frog kept at 21°
Inorganic P	100	100
Creatine P	49	78
Adenosin P (7 min. hydrolysed at 100°)	50	—
"Hexose" P (30 min. hydrolysed at 100°)	52	78
Product of 100 min. hydrolysis at 100°	45	—
Non-acid soluble residual fraction	9	38

A specific activity of the creatine phosphoric acid phosphorus amounting to 49 per cent of that of the inorganic phosphorus indicates that 49 per cent of the creatine phosphoric acid molecules present in the resting muscle were split and newly synthesized through enzymatic action in the course of the last 3 hours before the frog was killed. As the total number of creatine phosphoric acid molecules present in the muscle can be assumed not to have changed during that time, in the resting muscle we are faced with a molecular rejuvenation of the creatine phosphoric acid to the above extent. The adenosin and the hexosephosphate molecules are rejuvenated to about the same extent as those of the creatine phosphoric acid. With increasing temperature, as is to be expected, the rate of molecular rejuvenation increases, and in the course of less than a day practically all creatine phosphoric acid molecules are renewed.

The new formation of some of the 'acid soluble' phosphorus compounds present in the blood also takes place to a very appreciable extent. In human blood 2 hours after intravenous injection of labelled sodium phosphate, the specific activity of the total acid soluble organic phosphorus, kindly extracted by Mr. A. H. W. Aten from the blood corpuscles, amounted to 20 per cent of that of the plasma inorganic phosphorus.

In experiments *in vitro*[2] in which dog's blood was shaken for 2·5 hours with labelled sodium phosphate, 1/25 of the total acid soluble molecules was found to be labelled and thus split and resynthesized under the action of enzymes. In the same *in vitro* experiments the formation of only very minute amounts of labelled phosphatides (less than 0·1 per cent) could be ascertained. Also in experiments *in vivo* labelled phosphatides were found to be present to an appreciable extent in the blood only after a very long time. The specific activity of phosphatide P extracted from human blood corpuscles 24 hours after administration of labelled sodium phosphate was found to be 40 times less than that of plasma inorganic P, showing the very low rate of rejuvenation of the phosphatide molecules present in the blood.

There is thus a conspicuous difference in the rate of rejuvenation of some low molecular water soluble compounds, as for example, creatine phosphoric acid, adenosin phosphoric acid, hexosephosphate, and non-water soluble products like phosphatides, nucleoproteins and similar compounds, present in the blood. This difference is closely connected with the fact that the first-mentioned compounds are at least partly rejuvenated through enzymatic action in the blood itself, while the latter are principally rejuvenated in the organs and carried from these in the blood stream. The measurement of the rate at which, for example, adenosintriphosphoric acid molecules are renewed can be conveniently used to determine the amount of enzymes the presence of which enables the exchange reaction to take place.

We wish to express our most hearty thanks to Prof. Krogh for all the biological material used, and to him and to Prof. Niels Bohr for their kind interest taken in this work. We wish also to thank Miss Hilde Levi and Mr. Ussing for their assistance.

Adsorption Potentials

Ehrensvärd and Sillén[1] have recently considered the interfacial potential difference between two immiscible or slightly miscible liquid phases containing electrolytes; they conclude that the E.M.F.'s across cells of the type

Calomel electrode	Electrolyte BA in water C_1	Non-aqueous phase	Electrolyte BA in water C_2	Calomel electrode

are not derived from true partition equilibria of the electrolyte between the aqueous phases and the adjoining regions of the oil phase, but from an "*ion adsorption equilibrium* between the aqueous phases and the interfacial layer".

The E.M.F. of a cell is not necessarily affected by the adsorption of ions or neutral molecules at one or more of the interphases. In the system

$$\text{metal } M \mid \text{solution of salt } M^+X^-$$

for example, in thermodynamic equilibrium, changes in the potential difference across the metal - solution interphase are controlled by changes in the chemical potential of the ion M^+ in the solution. If any substance is introduced into the system which is insoluble in the bulk phases and adsorbed at the interphase, no change of potential difference will occur. The added substance is insoluble and can therefore be shown not to alter the chemical potentials of the bulk phase components. If this substance has strongly polar molecules, and forms an oriented layer at the interphase, the distribution of electrical potential and of charged particles in the interphase will be altered by its presence, but no change in potential difference across the interphase will be observed.

There are two conditions in which adsorption potentials can affect the E.M.F. of a cell:

(1) When the interphase contains a boundary across which no charged particle can pass.

(2) When diffusion of ions as well as of non-ionized molecular species takes place across an interphase which is not in a state of equilibrium.

Type 1 maintains a constant charge on its double layer when left on open circuit. For solutions of a given composition, it takes up any potential which is initially imposed. It has no definite potential of its own; but changes in the composition of the solution at constant surface charge produce definite changes of potential which depend on the actual charge on the double layer. These changes of potential arise from the adsorption at the interphase of substances from the solution. The theory of adsorption at interphases of this type has been worked out by Stern[2], who assumes the validity of Langmuir's adsorption isotherm for such cases. An examination of the partition function for an interphase shows that this assumption is not valid for charged particles[3], but the general basis of Stern's theory is supported by work on dropping mercury electrodes and electrocapillary data[4].

Adsorption at interphases of Type 2 will result in general in altered diffusion rates, and may alter these rates differently in the case of different ions. Since the diffusion of neutral electrolytes, interchange of cations and interchange of anions all involve the superposition of electric currents flowing in opposite directions, a selective change in the rates of ionic diffusion may lead to a modified distribution of electric charge. Thus the interfacial potential difference will alter.

The formula for a diffusion potential may be written approximately as:

$$\Psi_\beta - \Psi_\alpha = -\sum_{i=1}^{i=s}\int_\alpha^\beta \frac{t_i}{z_i F}\cdot d\mu_i \quad \ldots\ldots \quad (1).$$

The integration is from homogeneous solution α to homogeneous solution β on the other side of the diffusion boundary, and all the terms have their usual thermodynamic significance. As $\mu_i = \mu_{oi} + RT \ln c_i f_i$ and μ_{oi} is a constant depending on the temperature, pressure and nature of the solvent, attempts to relate equation 1 to ionic concentrations when water and oil are diffusing into each other involve a consideration not only of the diffusion of each ion but also of the solvent; diffusion of the latter causes the partition coefficients to vary both in space and in time.

As the cells examined by Ehrensvard and Sillén take up definite potentials, their aqueous - oil interphases cannot be of Type 1. They claim that their observations are consistent with the theory of such an interphase. The early stages of the setting up of a diffusion gradient in oil-water interphases seem therefore to confine the diffusion to the first one or two molecular layers of the oil phase. For these layers, interchange equilibrium is rapidly set up. The subsequent extension of the region of diffusion into the non-aqueous phase is very slow. Kinetically, therefore, a continuous transition can take place from an adsorbed monolayer to a diffusion gradient. Mathematically, Equation 1 is formally valid for a completely polarizable interphase.

An Anomalous Case of Emulsification

IT is commonly supposed that an emulsion of two immiscible liquids is stabilized by the formation of an interfacial film of emulsifying agent molecules which, by their constitution and orientation, condition the emulsion type. Thus, according to the Gibbs' equation, those materials which reduce surface or interfacial tension should facilitate emulsification. Indeed the term surface tension depressor has become synonymous with emulsifying agent.

It has recently come to our notice that simple inorganic salts such as the alkali halides enable relatively stable emulsions of water in amyl alcohol to be produced. These salts are not surface active but tend rather to *increase* the interfacial tension of the system.

The stability of emulsions thus prepared bears no simple relationship to the concentration of salt in solution. In the case of emulsions stabilized by potassium iodide, the maximum stability appears to be attained at an electrolyte concentration of 0·05 *N*, while concentrations greater than normal inhibit emulsification completely. On the other hand, concentrations of potassium iodide so low as 0·001 *N* have considerable stabilizing action.

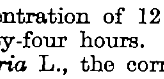
Control of Insects by Methallyl Chloride

IT is difficult to control insects in stored products, where they cause millions of pounds worth of damage annually. The most efficacious method is by fumigating them with poisonous gases or vapours. Many chemical compounds have already been tried, for example, by the United States Department of Agriculture[1].

I carried out some investigations upon methallyl chloride, and found that this material possesses good insecticidal qualities. It is a product manufactured from petroleum hydrocarbons and has the following formula:



$$CH_2=\underset{\displaystyle CH_3}{\underset{|}{C}}-CH_2Cl$$

Its specific gravity at 20° C. is 0·925 and its boiling point 72° C. It is a colourless liquid which evaporates easily at normal temperature. Mixtures of its vapour with air are not explosive in concentrations of 105–339 gm. per cub. m. It was H. F. Zimmermann at Prague who directed my attention to this product. It was found in the laboratory that species of *Ephestia* such as *E. kuhniella* Zeller and *E. elutella* Hb. were killed by a concentration of 12·5 gm. per cub. m. applied for twenty-four hours.

Calandra granaria L., the corn weevil, was killed by a concentration of 18·75 gm. per cub. m. applied for twenty-four hours at 18° C. The insects are not dead immediately after fumigation, but methallyl chloride proved to have a strong after-effect, so that within a few days all the insects are killed. Eggs, larvæ and pupæ are also killed. Imagines of *Calandra*, placed in the centre of a bag of wheat, were easily reached and killed by the gas.

It is surprising that if the fumigation time is reduced to one eighth (from twenty-four hours to three hours) only a four times higher dose is required, which is not in keeping with Haber's law ($c \times t = K$).

Five kgm. of methallyl chloride was evaporated, by pouring it on to flat dishes, in a gas chamber of 70 cub. m. capacity, containing bags of wheat and maize with *Calandra* species, bags of peas with *Endrosis lactella* Schiff., cases of currants and apricot stones with *Ephestia elutella* Hb. and *Paralispa gularis* Z., and also bags of cow hair with *Lermestes* species. At the end of twenty-four hours the gas was drawn off by suction. All the insects were killed. The temperature was 20° C.

A cocoa storage loft of about 150 cub. m., infested by tens of thousands of larvæ of *Ephestia elutella*, the cocoa moth, was treated in the same way at a temperature of 14° C. All the larvæ were exterminated.

In these tests, special attention was paid both to the influence of the gas upon the smell and taste of the gassed products and its toxicity to mammals.

As a soil insecticide, methallyl chloride was also used. Larvæ of the cockchafer were killed by a dose of 25 gm. per sq. m. distributed in four holes.

The great majority of plants are not damaged by methallyl chloride.

A detailed publication on methallyl chloride is being prepared and will be issued shortly.

Pterinopecten papyraceus and "*Strophomena*" *pecten*

Linnæus, in the tenth edition of "Systema Naturæ" 1758, p. 702, described a species *Anomia pecten* in these words: "A. testa semi-orbiculata depressa multistriata; valvula altera plana (List. angl. 243, t. 9, f. 49). Testa inferne ʃ. margine cardinis linea recta ʃ. transversa". No locality was given, but a specimen is contained in his cabinet at the Linnean Society, London.

Lister's figure, cited by Linnæus, is of a specimen "ex fodinis carbonum Fossilium juxta Hallifax", and is quite recognizable as *Pterinopecten papyraceus* (J. Sowerby, 1822) known to occur in the Halifax Hard marine band of the Coal Measures. The above description could be held to apply to this shell. By a strict application of the rules of nomenclature, J. Sowerby's specific name would appear to be invalidated by Linnæus's previously erected species.

On the other hand, there is no doubt that Linnæus had before him Swedish Silurian brachiopod shells long known as "*Strophomena*" *pecten* Linn. Knowledge of the typical form was spread by personal contact among the Swedish palæontologists, and the first figured specimen of '*S.*' *pecten*[1] is probably conspecific with the specimen still preserved in the Linnean cabinet.

This confusion seems to arise from a difference of method. Linnæus presumably only intended to show the general appearance of his shell to other workers, not to establish a type specimen.

Since *Pterinopecten papyraceus* is a common shell, cited in European literature for more than a hundred years, strict interpretation of the rules would lead to confusion. Therefore I am applying to the International Committee for Zoological Nomenclature for a suspension of the rules in this case, so that the specific name *pecten* Linn. can be retained for the Silurian brachiopod.

Other of the Linnean species are similarly referred to figures which do not represent the species in the modern interpretation, for example, such a common fossil as *Atrypa reticularis*, and if the rules are suspended in this case, a precedent will have been set up for the retention of those Linnean species at present doubtful.

If the rules are suspended, and '*S*'. *pecten* Linn. is retained, I propose to figure and describe the specimen of '*Anomia*' *pecten* in the Linnean cabinet as the neotype.

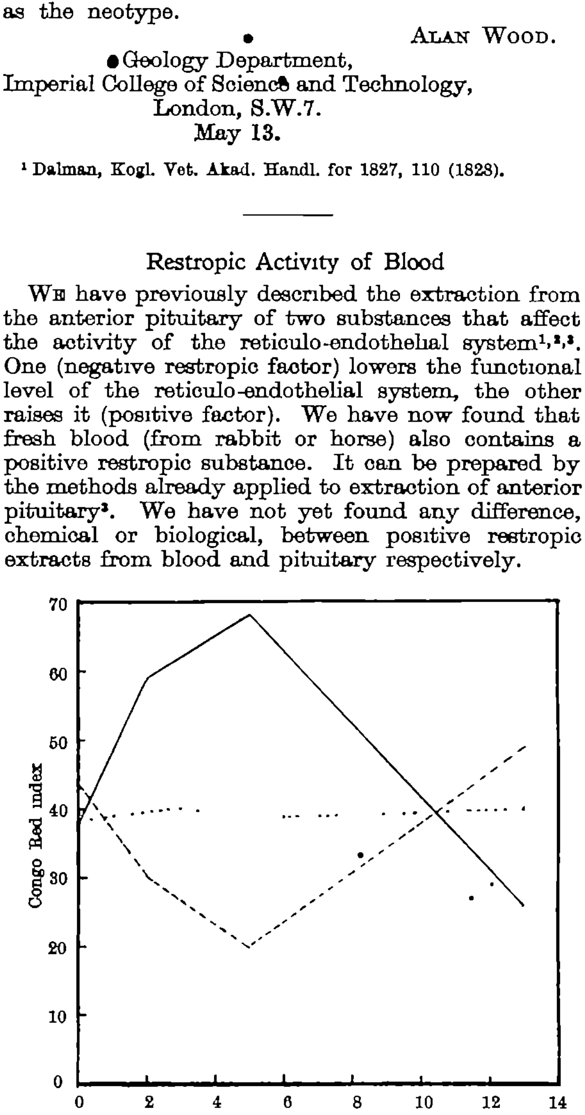
Restropic Activity of Blood

We have previously described the extraction from the anterior pituitary of two substances that affect the activity of the reticulo-endothelial system[1,2,3]. One (negative restropic factor) lowers the functional level of the reticulo-endothelial system, the other raises it (positive factor). We have now found that fresh blood (from rabbit or horse) also contains a positive restropic substance. It can be prepared by the methods already applied to extraction of anterior pituitary[3]. We have not yet found any difference, chemical or biological, between positive restropic extracts from blood and pituitary respectively.



Activity of the reticulo-endothelial system. Blood extracts from normal subject (full line), case of malignant disease (broken line), and case of cholelithiasis (dotted line).

The experiments have been extended to human blood. Samples of venous blood were obtained from healthy subjects and from various clinical cases. Each sample (5·0 ml.) was immediately extracted by a method previously described[3], deproteinization followed by aqueous extraction of the precipitate. The extract, made up to a volume of 5·0 ml., was injected into a rabbit in daily doses of 1·0 ml. The Congo Red index was again taken as measure of the activity of the reticulo-endothelial system[4]. This index was determined before, and 24 or 48 hours after, the first injection; further determinations were made one day and about ten days after the last injection.

The resulting curves of the activity of the reticulo-endothelial system varied greatly (see accompanying graph). All healthy subjects yielded extracts that rapidly increased the rate at which the dye disappeared from the blood. This rise in the Congo Red index was followed, on cessation of the injections, by a return to the initial level. Normal human blood thus contains a positive restropic factor.

The blood of patients exhibiting various clinical conditions (other than malignant disease) yielded either positive or inactive extracts. Entirely different results were obtained with extracts of blood from cases of malignant disease. Such extracts rapidly lowered the index. This negative restropic effect is usually noticeable 24 hours after the first injection, but may take several days for its full development. Exceptions were noticed in two cases, one showing a tumour of the parotis, the other diagnosed as carcinoma of the ear; these extracts were inactive. No case of malignant disease so far examined has yielded positive extracts; no case of non-malignant disease so far examined has yielded negative extracts.

It would thus appear that human blood contains substances affecting the active mesenchyme in the manner previously described for pituitary extracts. The concentration and the nature of the restropic substances seem to be related to the condition of the subject. The positive restropic activity of the blood of healthy subjects may be absent in some clinical conditions, as yet undefined; in malignant disease it tends to be reversed. There is as yet no evidence to show whether the absence of positive restropic, and the presence of negative restropic, factors in cases of malignant disease have a causative or merely a symptomatic significance.

The samples examined were obtained, together with the clinical diagnosis, through the courtesy of Dr. P. O. Ellison, pathologist to the Royal Northern Hospital, the staff of the Royal Cancer Hospital (Free), Dr. J. Patterson, pathologist to the Charing Cross Hospital and Dr. Rouillard of the Waterloo Hospital.

Cytochrome Oxidase

IN a recent paper on the indophenol oxidase, now known as the cytochrome oxidase, Keilin and Hartree[1] repeat the statement which they made in an earlier paper[2] that "According to Harrison[3], it is hardly necessary even to postulate the existence of an enzyme such as indophenol oxidase. The oxidation of *p*-phenylenediamine in muscle preparation he explains as a secondary or coupled oxidation by means of a peroxidase or a hæmatin compound acting in conjunction with H_2O_2 formed in a primary oxidation of substances such as glutathione or hypoxanthine". They then proceed to give arguments against this secondary oxidation theory, but the facts they quote merely show that the indophenol reaction of tissues is not *solely* due to secondary oxidation.

I was well aware of these considerations, but showed in a number of ways that the indophenol oxidase theory alone does not explain all the experimental facts relating to the indophenol reaction; for example, the production of a positive reaction on adding hypoxanthine to liver suspension, even in presence of cyanide, which is known to inhibit the activity of the indophenol oxidase. What I actually said in concluding my paper was: "I feel that the explanation of the indophenol reaction and its significance in cell oxidations is best accounted for by assuming a combined action of an indophenol oxidase, as suggested by Keilin, and the secondary oxidation mechanism suggested in this paper. These together afford a satisfactory explanation of the observed facts."

So far from not believing in the existence of an indophenol or cytochrome oxidase, I carried out experiments shortly afterwards to show the interaction of a dehydrogenase system (glucose dehydrogenase) with the cytochrome-oxidase system as postulated by Keilin. These experiments gave a positive result[4] and have recently been confirmed in this laboratory.

The amount of secondary oxidation by hydrogen peroxide occurring in the intact tissues is at present unknown, but there is no reason to believe that it is negligible; indeed Keilin and Hartree[2] have themselves recently extended the number of systems which are known to be capable of bringing about secondary oxidations.

Dismissals of Scientists in Austria

BRITISH and other scientists will be interested to know the position of some of their colleagues in Austria since the recent annexation of that country. It is difficult to get reliable information, as the dismissals, arrests and other measures of repression are not officially published, and the state of affairs in the Austrian universities and technical schools changes from day to day. Nevertheless, it is possible to give a preliminary and incomplete account of what has been happening in the field of the natural sciences. It should be borne in mind that the state of affairs in other fields is likely to be worse, since the natural sciences do not touch on political questions, while philosophy, history, sociology, etc., do.

The following is a list of professors of the natural sciences who have been dismissed (lecturers and assistant professors are not included):

Prof. Emil Abel, physico-chemist, Technical High School of Vienna.

Prof. Benndorf, physicist, University of Graz.

Prof. Felix Ehrenhaft, physicist, University of Graz.

Prof. Fritz Feigl, analytical chemist, University of Vienna.

Prof. Fuerth, physiological chemist, University of Vienna.

Prof. Philipp Gross, physico-chemist, University of Vienna.

Prof. Victor Hess, physicist, University of Graz (Nobel Prize winner).

Prof. Mark, physico-chemist, University of Vienna.

Prof. Stephan Meyer, director of the Radium Institute of the Academy of Sciences, Vienna.

Prof. Pauli, colloidal chemist, University of Vienna.

Prof. Karl Przibram, physicist, University of Vienna.

Prof. Hans Thirring, theoretical physicist, University of Vienna.

Prof. Otto Redlich, physico-chemist, Technical High School of Vienna.

Among the arrested are:

Prof. Baule, mathematician, University of Graz.

Prof. Karl Buehler, psychologist, University of Vienna (since released).

Prof. Dobretsberger, rector of the University of Graz.

Prof. Loewi, physiological chemist and pharmacologist, University of Graz (Nobel prize winner).

The following professors have been dismissed from the famous medical school of Vienna:

Drs. Julius Bauer, Richard Bauer, Bustin, Elias, Erlacher, Leopold Freund, Froschels, Glaessner, Glas, Gottlieb, Julius Hass, Walter Hausmann, Hammerschlag, Leo Hess, Oskar Hirsch, Hecht, Lieben, Ernst Lowenstein, Marburg, Henrich Neumann, Moriz Oppenheim, Pappenheim, Paschkis, Ernst Pick, Pollak, Porges, Ranzi, August Reuss, Sauser, Schilder, Schueller, Schur, Gottwald Schwarz, Max Sgalitzer, Scheminzky, Sicher, Silberstein, Stern, Stransky, Robert Stein, Weninger, Willheim, Emil Zak, Walter Zweig. Dr. Bruecke, of Innsbruck, has also been dismissed.

Among the physicians:

Prof. Ferdinand Blumenthal, the German authority on cancer, who was living in Vienna, is in prison; Prof. Oskar Frankel, the gynæcologist and histologist, and Prof. Knoepfelmacher, the well-known specialist in children's diseases, have committed suicide.

It must be pointed out that these measures have been directed against men of varying political convictions, and have hit those who were active in the Christian movement and those who were simply opposed to official Nazi principles, as well as democrats, socialists and Jews.

Darwin Misunderstood

To argue fully Sir Edward Poulton's two main points[1] against my biography—the "fragmentary" nature of Darwin and his "fear" of his father—would take more space than I can ask for. I will only remark on the first point that the term "fragmentary" was intended by me to refer primarily to categories of imaginative and intellectual activity, and that my case is not even touched by the fact that Darwin was, as everyone knows, the best of neighbours and friends; and on the second point that no more is Darwin's alleged "fear" of Robert Darwin disproved by citing his "boundless and most touching reverence," since—as any psychologist might testify—it is the very "boundlessness" of that reverence which suggests some hidden and contradictory motivation, lying in all probability, I would hazard, below the threshold even of Charles Darwin's own consciousness.

I stand by both these points (though admitting that the second can be of its nature only speculative), but I will readily confess that in relation to the first some of my statements were either too bold or too bald—sometimes both—and have been amended in the American edition published last month by the Yale University Press, where the sub-title "The Fragmentary Man" has been retired from the title-page to its proper place—the final chapter which I myself would prefer to regard as a personal comment upon, rather than integral part of, my biography. To make my point of view—which is one of the highest admiration for Darwin as man *and* as scientist—rather clearer, I should like to quote a few lines which appear in my American but not English preface to the book: "If I would attack anything, it is neither Darwin nor even Darwinism but dogmatism, above all that dogmatism which regards its own particular truth—whether scientific, artistic, or religious—as final. Like Emerson, I do not believe in final truths, nor do I regard it as a derogation of a great man to indicate that he, like every other natural creature, had his limitations. On the contrary, I would contend that greatness only yields its full harvest when its limitation is completely understood."

I should also like to stress the fact that my book is primarily a biography—in nineteen, indeed, out of twenty chapters—and not only of Charles Darwin but also of his grandfather Erasmus, and of the immediate Darwin and Wedgwood families from 1730 to 1896.

Geoffrey West.

22 Lathbury Road,
Oxford.

---

[1] Nature, 141, 807 (May 7, 1938)

Those who have read the words quoted from Mr. Geoffrey West's book will have formed their own opinions upon the fairness of my comments. I feel sure that they will be glad to learn the intentions of the author and also to know that the word "fragmentary" is not prominent in the American edition.

Convergent Sunbeams

I can add to the correspondence on the above subject in Nature of February 19 and March 26 by reporting that I have observed the phenomenon on numerous occasions at Diyatalawa, a village at an altitude of 4,000 ft. on the eastern side of the central hills of Ceylon. The western horizon about eight miles away is the edge of a block of rough mountainous country with many peaks of about 7,000 ft. altitude (including the well-known Adam's Peak). During the clear weather of spring and summer, I frequently observed the shadows converging on the eastern horizon at sunset, and I used to wonder if they could be produced by prominent peaks as well as by clouds.

Preparation of Radio-Element $^{32}_{15}P$ by Means of an Electric Field

I WISH to correct slightly my recent letter in NATURE[1] on this subject. The number of neutrons emitted by a radium plus beryllium neutron source has been accurately measured (C. J. Bakker[2] and other observers) and found to be $(2 \cdot 1 \pm 0 \cdot 2) \times 10^4$ neutrons per sec. per mC. radium. The source of 120 mgm. used in our experiments emitted during nine days about $1 \cdot 96 \times 10^{12}$ neutrons. If each neutron transformed an atom of sulphur into radio-phosphorus (ideal case certainly not realized) we should obtain $1 \cdot 96 \times 10^{12}$ atoms of $^{32}_{15}P$ weighing about 10^{-10} gm. Hence the coloration and the increase in weight of 3·7 mgm. of the electrode in our experiment cannot be due to the radio-phosphorus.

Nevertheless, as is shown by our experiments on the photographic action of the electrodes[3] and the measurements with the Geiger-Müller counter, practically all the activity is collected on the electrodes. Spectroscopic and chemical experiments are proceeding in order to determine the cause of the coloration and increase of weight of the electrodes.

Note added in Proof. After sending the above correcting letter, Prof. F. A. Paneth (London), M. Goldsmith (Paris) and Dr. J. Tandberg (Stockholm) wrote pointing out that, in connexion with the number of kicks per minute observed, we obtain a quantity of radio-phosphorus weighing less than 10^{-11} gm. I had myself made a similar calculation, but have not mentioned it above in order not to occupy further space needlessly.

Points from Foregoing Letters

New values for the 'packing fraction' of atoms of titanium (mass 48), chromium (mass 52), nickel (mass 58) and bromine (mass 79 and 81) are given by Dr. F. W. Aston, as calculated from mass spectrographic measurements on doublets (electrically charged atoms and groups of atoms having the same mass/charge ratio). A knowledge of the packing fraction is necessary in calculating energy changes involved in atomic transmutations.

Clarifying and commenting on some of the statements on resonance and nuclear photo-effects, dealt with in a previous note, Prof. N. Bohr points out that in the case of strictly monochromatic radiation one cannot separate the initial excitation of a certain mode of oscillation from its subsequent quenching due to coupling; also the selectivity is independent of the ratio between the chances of the re-emission of the whole energy as a single radiation quantum in the initial and in the subsequent stage of the excitation process.

A temperature gradient in liquid mercury has been shown to give an electromotive force, the current flowing in the external circuit from the hot to the cold side (first "Benedicks effect"). Further experiments by Prof. C. Benedicks and P. Sederholm show that when the mercury is purified and freed from gas the E.M.F. changes sign. The author suggests that the known anomalous behaviour of mercury, which gives a negative sign for the Thomson effect, might also disappear if suitably purified mercury were used.

By injecting labelled radioactive sodium phosphate into frogs and afterwards determining how much of the labelled phosphorus is combined as creatine phosphoric acid, Prof. G. Hevesy and O. Rebbe find that, in the course of a day, practically all molecules of creatine phosphoric acid in the muscle are broken up and 'rejuvenated'. The phosphatide molecules in the blood of the dog, on the other hand, were found to take up only a small amount of labelled phosphorus during 24 hours, indicating a low rate of rejuvenation.

Messrs. Craxford and Gatty and Lord Rothschild discuss the theory of adsorption potentials and some recent work of Ehrensvärd and Sillén on this subject. From the results obtained by the latter, the authors conclude that the early stages of a diffusion gradient in oil-water interphases may confine the diffusion to the first one or two molecular layers of the oil phase.

D. F. Cheesman, A. King and Dr. J. N. Sugden report that certain inorganic salts, such as potassium iodide, while increasing the interfacial tension, have the property of stabilizing the emulsion of water in amyl alcohol.

Tests have been carried out by C. J. Briejèr to determine the insecticidal effect of methallyl chloride in a gaseous condition. This material proved to be efficacious for combating insects both in stores and in the soil.

Dr. A. Wood is applying to the International Committee for Zoological Nomenclature for a suspension of the priority rules, which would enable the specific name *pecten* Linn. to be retained for the Silurian brachiopod which Linnæus probably had before him, rather than it should be applied to *Pterinopecten papyraceus* from the coal measures, which was figured by Lister and cited by Linnæus.

The blood of the rabbit, horse, and also of normal human beings, is found by C. Wetzler-Ligeti and Dr. B. P. Wiesner to contain a positive 'restropic' substance, that is, to increase the activity of the reticulo-endothelial system, as measured by the 'Congo-red index'. The blood of human patients suffering from cancer was found to be either inactive or more generally to have a lower Congo-red index.

Prof. D. C. Harrison states that while he does not doubt the existence of the enzyme 'indophenol oxidase' (also known as cytochrome oxidase), as postulated by Keilin and Hartree, this alone does not explain all the experimental facts observed; for example, the production of a positive indophenol reaction on adding hypoxanthine to liver suspension in the presence of cyanide, which inhibits the activity of the indophenol oxidase. To explain satisfactorily the indophenol reaction of the cell oxidations Harrison postulates an additional secondary oxidation by hydrogen peroxide, of a similar mechanism.

Research Items

Ancient Pottery from Peru

A SERIES of ancient Peruvian vases presented to the Department of Ethnography of the British Museum (Bloomsbury) by the Christy Trustees has been described and figured by Mr. H. J. Braunholtz (*British Museum Quarterly*, 12, 2, 1938). Some examples are without parallel in any other collection. Of the thirty-seven vases, thirty-one unmistakably belong to the Nasca region of the southern Peruvian coast. The remaining six are of Early Chimu and Chimu types from northern Peru. It is still impossible to assign any more precise dating to the Nasca or proto-Nasca ware than the first half of the first millennium A.D.; but as a result of a detailed analysis by Kroeber, this ware has been divided into three groups, forming a chronological sequence, A and B with an intervening X. By this definition the figure vases with modelled heads in the British Museum series fall into group B, while the flaring bowls, though having A shapes, are also to be assigned to group B on account of their painted designs. The 'jagged staff demon', a mythological figure, is characteristic of the B group, and a progressive subordination of realism to decorative purposes is shown in the suppression of the body and the disconnected treatment of the legs. Figure vases representing women have variations of the 'jagged staff demon' painted on their cloaks at the back. Modelled figures, especially animals and birds, from Nasca are rare. Some interesting points are raised by those in this series. The style and colour justify their inclusion in Early Nasca, but a double-bodied figure representing an owl is typical rather of northern Peru, where such figures belong to the Late Chimu period, considerably later than Early Nasca. This specimen has a further affinity with Chimu in being a whistling vase. Another vase in the form of a snake or eel-like creature is also of the whistling type.

Decorative Art of the Australian Aborigines

DR. DANIEL SUTHERLAND DAVIDSON, assistant professor of anthropology in the University of Pennsylvania, under a fellowship grant of the Science Research Council of New York, has made a study of the decorative art of the aborigines of Australia, based upon an examination of material in the Australian museums, and on field work in north Australia (*Mem. Am. Phil. Soc.*, 9; 1937). This study is to be regarded as preliminary, in view of the absence of information from certain specific localities and the difficulty of securing painted, as opposed to incised, objects. Aboriginal paint is impermanent, and certain classes of painted objects are always burnt at the close of the ceremonies in which they are used. Only objects of major regional or continental significance have been considered. The aborigines gave considerable attention to the decoration of their possessions, utilitarian and sacred. Much Australian art is primarily æsthetic, but much also of profound religious significance. Designs are usually applied by incising or painting. Other techniques are employed, but little is known of this subject, or of symbolism and design analysis. Many of the designs are of local distribution. Others are scattered all over the continent. Although the psychological incentives are more or less constant, the expression in design and technique varies according to historic influences. The continent basically seems to be an art unit, historically considered. Available evidence in respect of contemporary art indicates that Australia can be divided into five roughly determined and overlapping design areas, each divisible into sub-areas. These areas have permanent characters; but changes in design and styles of portrayal are currently taking place as the result of diffusion and local elaborations.

Cerebro-spinal Fluid

THE content of a series of lectures on the meninges and the cerebro-spinal fluid delivered at University College, London, has recently been given by Prof. L. H. Weed (*J. Anat.*, January 1938). The article furnishes an interesting account of the history of the discoveries and theories relating to this subject from as far back as Alexander Monro, 1783, up to the present day, when a considerable amount of research on it is being carried out in the author's laboratories. It is now established fairly satisfactorily that the cerebro-spinal fluid is secreted by the choroid plexuses and thence passed into the neural cavities. The excess passes from the 4th ventricle into the subarachnoid space and thence, via the arachnoid papillæ, directly into the venous system. The cerebro-spinal cavity is regarded as a closed system which protects its contents from changes in atmospheric pressure. When man's precursors adopted an upright posture, it naturally affected the pressures in the column of fluid in the cerebro-spinal cavity, and apparently no protective mechanism has been developed to meet this. It is not so serious a problem as might be expected since, as the author shows, the closed cerebro-spinal system has a morphological and physiological mechanism whereby the volume of the brain can vary, the volume of the blood can vary, the volume of the cerebro-spinal fluid can vary, but the total volume of the whole contents of the system can remain relatively constant.

Genotypic Selection for Weight in Mice

AN interesting experiment in selection for increased size in the albino mouse is described by Dr. H. D. Goodale (*J. Heredity*, 29, No. 3). He used the method of genotypic rather than phenotypic selection, that is, selection by progeny test. The experiment began in 1930 with 4 males and 8 females, a similar number being added the following year. The thousandth male was born three years later, and all descendants since that date, January 1934, are derived from 16 mice. The males at first averaged 26 grams and the females 21·3 grams. Matings were made only on the basis of weight at two months after birth and without regard to relationship or age; so the generations overlap, ranging from 12 to 16 for the whole experiment to date. The mean weight shows a steady increase, the last 500 males averaging 36·4 grams, an increase of 40 per cent. The present average weight exceeds by several grams the maximum weight of mice in the early generations. It is suggested that the present results indicate the presence of at least 32 pairs of genes affecting weight. The results can be explained in terms of the multiple factor hypothesis ; but there is no indication that the limits of size are being approached, or of the number of genes affecting size which may be present. The results are not attributed to the occurrence of size mutations during the experiment, but to the method of selection adopted.

Metabolism in Lepidoptera

MR. I. W. KOZHAUTSHIKOV, of the Zoological Institute, Academy of Sciences, Leningrad, has recently published an article on the above subject (*Bull. Entomol. Res.*, March 1938). It is concerned with carbohydrate and fat metabolism in certain moths, namely, the common species *Agrotis segetum*, *Pyrausta nubilialis* and *Loxostege sticticalis*. Moths reared from caterpillars, bred under optimal conditions, were used in these experiments just after they had emerged. It appears that fat synthesis is of great importance in the metabolism for the maintenance of the body weight with the same supply of energy and for egg-yolk production. Moths increase their live weight by the consumption of sugar solution often by 40–50 per cent, but the fat synthesis out of sugar, and the water output, rapidly reduce the live weight to normal. Changes in the respiratory quotient show a peculiar metabolic phase after carbohydrate nutrition due to fat synthesis. The fat synthesis of carbohydrates results in a decrease in oxygen consumption for the reason that the oxygen liberated by the fat synthesis reaction is utilized. The author recognizes two types of specialization of carbohydrate metabolism as being present in adult insects. He quotes Beutler (1936) as showing that in bees, sugar is used directly without transformation into fat, and no reserves of fat have been observed in these insects. The reserves of sugar are found in the stomach, and the activity of the insect is only possible so long as these reserves are not used up, feeding being necessary many times a day. In Lepidoptera, on the other hand, a large quantity of sugar can be taken during a short period and utilized after its transformation into fat. Feeding is not necessary every day for some species, and they can live for their normal period, even if food is taken only once during the first few days of adult life.

Agaricaceæ of Hokkaido, Japan

AN extensive, detailed survey of the agaricaceous fungi which occur in Hokkaido, Japan, has recently been published by Sanshi Imai (*J. Fac. Agric. Hokkaido Imp. Univ.*, 43, Pt. 1, 1–178, with 3 plates, March 1938). Studies were commenced in 1924, and now twenty new varieties are described, many of them for the first time. A modified classification is used, which accommodates the Japanese species without rupturing well-established groups. New tribes and subgenera are established with Latin diagnoses, whilst the descriptions of species are detailed, and in English. The volume is critical and contains adequate references ; it provides a fitting superstructure to the modest mycological foundations first laid in Japan in 1860 by two British investigators, M. J. Berkeley and M. A. Curtis. Thirty-two excellent halftone illustrations, combined into the three plates, include many of the new species, and also show a few kinds which are common in England. The general impression of the present volume, however, is that of a special flora, typical of Japan, and having but little in common with other fungus floras of regions in the same latitude.

Crystalline Preparations of Potato Virus *X*

THE virus of tobacco mosaic has been isolated as a crystalline nucleo-protein of high molecular weight. This particular virus has, however, many properties different from other viruses, and it did not appear safe to assume that the others would have similar composition. Messrs. F. C. Bawden and N. W. Pirie have recently shown (*Brit. J. Exp. Path.*, 19, 66–82, 1938) that the *S* and *G* strains of potato virus *X*, isolated from infected tomato, tobacco or *Nicotiana glutinosa* plants, do indeed yield nucleo-proteins, which can be prepared as liquid crystalline extracts. No such preparations could be isolated from healthy plants, and all available evidence suggests that they are the viruses themselves. Concentrated solutions were spontaneously birefringent, and dilute solutions exhibited anisotropy of flow, as was established for tobacco mosaic virus. Filterability and various types of inactivation were described for both viruses. Potato virus *X* is perhaps more typical of viruses in general than tobacco mosaic, so it seems more probable that all viruses may be specialized nucleo-proteins.

Desiccation in West Africa

THE problem of progressive desiccation in the western Sudan between the Sahara and the humid belt has received much attention in recent years. Prof. E. P. Stebbing recently developed a theory of the steady encroachment of the Sahara on Nigeria and the replacement of the natural vegetation by drier types. The problem has lately been investigated by an Anglo-French Forestry Commission in northern Nigeria and the French Niger colony. In an article in the *Geographical Journal* of May, Mr. Brynmor Jones reviews the evidence especially as regards northern Nigeria and reaches somewhat different conclusions from those of Prof. Stebbing. Silting up of streams and river capture have reduced the amount of surface water on the fringe of the Sahara, but this process is very slow and does not contribute an immediate threat to the prosperity of the West African colonies. It can, moreover, be delayed by protection of head waters and by flood control. Protection of forests in certain places in order to check erosion is advisable, and the practice of shifting agriculture is certainly harmful in the drier parts in accelerating erosion. But Mr. Jones finds little evidence that depopulation is due to desiccation. He attributes it rather to political and economic factors, inter-tribal wars, slave raiding and pestilence. He is guarded on the problem of climatic changes. These have no doubt occurred since the Quaternary period, but changes are too slow to be noticeable in the space of a few hundred years. Minor oscillations are characterized by cycles of years of relatively high or relatively low rainfall. The last major change appears to have been one towards more humid conditions.

Volcanic History of Montserrat

EARLY in 1936 the Royal Society, in collaboration with the Colonial Office, organized an expedition to Montserrat, with the object of studying the geology of the island and of investigating earthquakes and soufrière activity that had caused considerable damage and alarm in the two previous years. A. G. MacGregor, the geologist of the expedition, has now published the results of his investigations (*Phil. Trans. Roy. Soc.*, B, 229, 1–90 ; 1938). An outline of the geological history and structure of the island and an account of the active soufrières is followed by a detailed petrological study of the rocks. The latter are mainly labradorite-dacites and olivine-basalts, but nevertheless they represent almost the full range of types known in the Caribbean volcanic arc. The chemical characters are brought out with the aid of seven new analyses, and it is shown that there are many analogies with the Lassen Peak district of California. Special attention is devoted to cognate xenoliths and dome formation; magmatic corrosion of feldspar phenocrysts; oxidation and resorption of hornblende; origin of breadcrust bombs of the peléan type; and the occurrence of tridymite and cristobalite. It is pointed out that prediction in regard to future events in the Lesser Antilles is made difficult by the lack of continuous scientific records of past soufrière activity and earthquakes. Since 1692, the longest period that has elapsed without volcanic disturbance somewhere in the arc is 47 years, but on seven occasions the interval of tranquillity has been seven years or less. There is thus every reason to believe that eruptions or earthquakes will be renewed in the arc at no very distant date, and probably more than once in the lifetime of the present generation.

Methylene

THE methylene radical, CH_2, has often been invoked as an intermediate in combustion reactions, the thermal decomposition of hydrocarbons, and other processes. The first direct evidence of its existence was obtained in photochemical investigations on the decomposition of keten: $CH_2:CO = CH_2 + CO$. T. G. Pearson, R. H. Purcell and G. S. Saigh (*J. Chem. Soc.*, 409; 1938) now describe the formation of methylene from keten and diazomethane ($CH_2{:}N_2 = CH_2 + N_2$) by thermal and photochemical decomposition. Keten is not easily decomposed thermally to give methylene but readily does so when exposed to light of 2580–3130 A. Diazomethane is thermally decomposed to produce methylene. The apparent life of the methylene was different when produced from keten and diazomethane, being very long in the first case and similar to that of an alkyl radical in the second. The methylene was detected by reaction with selenium and tellurium. The authors describe a large amount of experimental work and they consider that their results show that free methylene should be regarded as a highly reactive molecule rather than a free radical in the sense that methyl is. Its persistence is therefore a function of its environment, as indicated by the varying life when obtained from different materials. A consequence of this point of view is that the carbon atom in methylene is essentially bivalent, or in a ^3P state, as postulated by Nef and others and recently emphasized by Norrish and collaborators.

The *p*H Scale

IT is customary to determine pH values by means of the equation (1): $pH = (E-E_0)/2{\cdot}3026(RT/F)$, where E is the potential of the cell: (Pt), H_2: solution X: KCl sat.: reference electrode (A), and where E_0 is a constant at a given temperature, depending on the nature of the reference electrode. It is also customary to interpret pH according to the equation: $pH = -\log a_{H^+}$, where a_{H^+} is the hydrogen ion activity. This procedure is based on the belief that the liquid junction potential at the boundary between solution and saturated KCl solution is very small or constant. D. A. MacInnes, D. Belcher and T. Shedlovsky (*J. Amer. Chem. Soc.*, 60, 1094; 1938) direct attention to certain difficulties in this procedure, and propose another method of calculation in which the equation (1) is retained, but they adjust the thermodynamic quantities as closely as possible by means of a shift of E_0 from the value commonly used. For this purpose, buffer solutions were used as solution X. If C_{HA} and $C_{A'}$ are the concentrations of weak acid and its anion in the buffer solution, they find that $pK' = pH - \log (C_{A'}/C_{HA})$ has, up to an ionic strength $\mu = 0{\cdot}01$ mol./lit., an empirical value $pK' = pK_0 - B\sqrt{\mu}$, where pK_0 and B are constants. The value of E_0 is then adjusted so that the equations yield a value of pK_0 equal to the thermodynamic constant pK. The pH values of commonly used acetate and phthalate buffers were so redetermined at three temperatures. The authors point out that the uncertainties in the liquid contact potentials and the theoretical impossibility of finding single ion activities lie at the root of the present difficulties in setting up a pH scale.

Visible Radiation of Electrons in Pure Liquids

P. A. CHERENKOV (*Bull. Acad. Sci. U.R.S.S.*, 491; 1937) finds that when fast electrons (β-rays or Compton electrons) pass through pure liquids they cause a faint visible radiation showing unusual properties. The spectrum is continuous and extends into the far ultra-violet; the energy distribution shows an increase to shorter wave-lengths. The most characteristic feature of the radiation is its asymmetrical distribution in angle around the path of the electron. According to a theory developed by I. M. Frank and I. F. Tamm, the radiation is due to the velocity of the electrons in the medium being greater than the phase velocity of light in the medium.

Markings on a Satellite of Jupiter

UNDER the title "Markings of the Third Satellite of Jupiter in Transit across the Planet", a paper by Dr. E. M. Antoniadi has recently appeared (*J. Brit. Astro. Assoc.*, 48, 7; May 1938). At the end there are several notes by Mr. B. M. Peek, director of the Jupiter section, in which he refers to the work of other noted observers, more especially members of the British Astronomical Association. Dr. Antoniadi has produced some very beautiful drawings showing the appearances presented by satellite iii in transit in 1927, and beside these he has placed drawings made by W. R. Dawes during transits in 1849, 1860 and 1867. The evidence that the satellite rotates in the same period that it requires to revolve around Jupiter can now be considered established. The author of the paper points out that although satellite iii is frequently represented as larger than satellite iv, this is not correct. Satellite iv is actually the largest of all such bodies in the solar system. Another interesting matter is referred to. Although the mass of the satellite is more than twice that of the moon, yet the velocity of escape is almost comparable from the gravitational point of view. But as the satellite receives considerably less heat than our moon, the velocity of the gaseous molecules is thereby lessened, and it is possible that the satellite may have a highly rarefied atmosphere of heavy gases. The apparent distortion of satellite iii, which has been noticed by many observers, presented a difficulty until 1921, when the Rev. T. E. R. Phillips showed that it was due to the spots of the satellite.

Hydrobiology and Fisheries Laboratory, Alexandria

IN a review that appeared in NATURE[1] of some publications of the Directorate of Hydrobiology and Fisheries, Egypt, F. S. Russell concludes thus: "Now that research is on so sound a footing, the Egyptian Government should see grounds for fostering and furthering investigations in this most interesting region". Dr. C. Crossland has already described in NATURE[2] the Marine Station of the Egyptian University at Hurghada on the Red Sea, and a short description of the Egyptian Government Laboratory on the Mediterranean at Alexandria may be of interest.

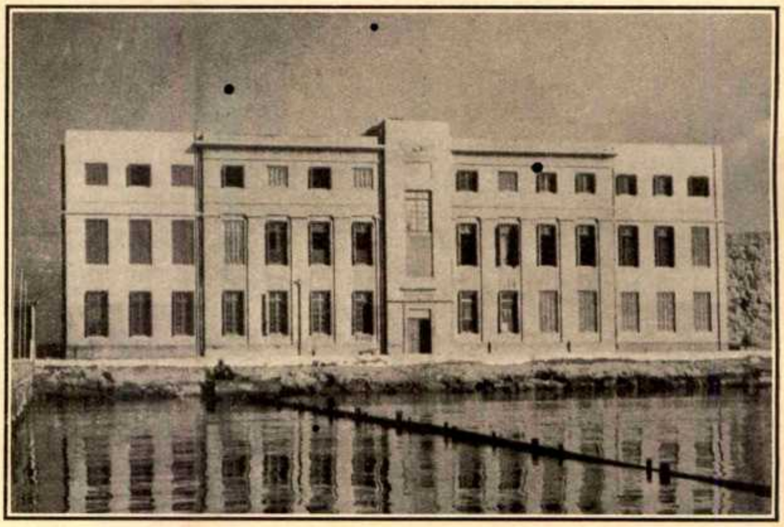
The favoured position of Egypt overlooking two seas, the incomplete knowledge we possess of the Eastern Mediterranean basin, and the existence of two main factors influencing that basin, namely, the opening of the Red Sea on the Mediterranean through the Suez Canal, and the Nile flood arriving at the coast by the end of summer, and throwing great quantities of freshwater into the Mediterranean—all these facts present problems of exceptional interest for research workers in aquatic biology.

The Cambridge Expedition to the Suez Canal[3] has already proposed to repeat its exploration after a lapse of only ten years. Workers at the Hydrobiology and Fisheries Laboratory have carried out some research round Alexandria, in which the effect of the Nile flood on the area is incidentally touched upon. In the Suez Canal, the regime of currents has been studied by monthly observations of salinity, oxygen content and temperature at nine stations on the Canal; and the movements of the phytoplankton have been examined at six stations. These studies must be continued in order to observe any changes produced by the Red Sea waters reaching the Mediterranean for at least nine months every year, and the Nile flood water breaking, between September and August, through the earth barrages artificially raised at the mouth of the delta every year in February.

The Laboratory at Alexandria offers facilities for visiting scientific workers to proceed with research on these lines, or in any other direction. A launch is attached to the Laboratory, for short coastal trips, and the research steamer *Mabahiss* can be used for more important cruising.

The laboratory is a three-storied building, situated on the tongue of land supposed to be the promontory of Pharos Island, on which stood the famous lighthouse of the Ptolemies. It overlooks, from the south-eastern side, the bay now known as the Eastern Harbour, and from the north-western side, the open sea. This situation unites the advantages of being right near the sea, and of being twenty minutes journey by bus or tramway from the centre of the town of Alexandria. Accommodation for living on the premises of the laboratory is thus rendered unnecessary.

The ground floor contains the show-aquarium, with twenty-four tanks, and sea or fresh-water *ad libitum*. There are four research cubicles, with sea and fresh-water laid on to taps, and possibility of establishing research aquaria when needed. The chemical store, a dark-room, bath-room, lavatories, and store-room for gear, etc., complete the ground-floor.



THE ALEXANDRIA MARINE LABORATORY.

There are seven research laboratories on the first floor; there are incubators, fume cupboard, electric centrifuge, accurate balance and refrigerator. The offices and the Director's laboratory complete this floor.

The library and the museum occupy the second floor.

On the roof is a cement tank for sea water, with pipes to the aquaria and the laboratories. Sea water is brought in to another cement tank at the basement of the laboratory by an 'eternite' (asbestos and cement combined) pipe laid for sixty metres in the water of the Eastern Harbour; water is drawn from this tank by electric pumps which either send the water to tanks under the ground floor, where it can be filtered, or directly to the roof-tank.

Applications for work and for more ample information, should be sent to the Director, Marine Laboratory, Kayed Bey, Alexandria.

HUSSEIN FAOUZI.

The London Television Service

A MEETING of the Institution of Electrical Engineers held on April 21 was devoted to a series of papers describing the development of the television broadcasting service which has been operated by the British Broadcasting Corporation at the Alexandra Palace station since August 1936. The first paper, by Messrs. T. C. Macnamara and D. C. Birkinshaw entitled "The London Television Service", recalled certain early electrical discoveries which laid the foundations of modern television. The Nipkow scanning disk was invented in 1884 and is still in use in certain systems to-day; while in 1908, A. A. Campbell Swinton described the forerunner of the present-day cathode ray tubes used both for scanning and for reproduction purposes.

In 1929, arrangements were made between the B.B.C. and Baird Television, Ltd., for the first regular transmissions from a London station of television programmes of the low-definition type, using 30-line scanning and 12½ pictures per second. Some five years later, His Majesty's Postmaster-General appointed a committee under the chairmanship of Lord Selsdon to review the development of television and to advise on the conditions under which a public service should be conducted. The recommendations of this committee were put into effect in August 1936, by the inauguration of the London Television Station at Alexandra Palace. After a trial period, in which the technical merits of two systems of high-definition television were compared, the same committee announced in February 1937 that the London station would in future use the Marconi–E.M.I. system with its interlaced scanning with 405 lines and 25 frames per second. The use of interlaced scanning is advantageous in that it has the apparent effect of increasing the picture-repetition frequency to 50 per second, at which no flicker is perceptible to the eye, without increasing the band of modulation frequencies required.

A detailed discussion of the development of this standard of scanning with a specification of the radiated wave-form employed is given in the second of the series of papers, entitled "The Transmitted Wave-form", by A. D. Blumlein. The transmission is of the so-called direct-current type in that there is no fixed average value of the carrier wave amplitude. Under normal running conditions, with no transmitted picture, the 'all-black' condition is represented by the carrier wave amplitude being at 30 per cent of its peak value, the line and frame synchronizing impulses reducing this to zero amplitude at the appropriate intervals. This arrangement of the conditions is claimed to minimize the effect of interference on the synchronism of the received picture. The 'all-white' condition is represented by full modulation at the peak amplitude, so that the vision signals occupy values between 30 per cent and 100 per cent of the radiated carrier. Details of the equipment which has been developed to handle the modulation which arises from this method of transmitting the picture signals are given in the third paper, entitled "Vision Input Equipment", by C. O. Browne. This paper includes a cursory description of the technical features of the equipment, and contains a list of references to more detailed information.

The fourth and last paper of the series was presented by Messrs. N. E. Davis and E. Green under the title "The Radio Transmitter". The vision transmitter at the London station was designed to give a peak output power of 17 kw. when a steady condition is maintained corresponding to the transmission of a full white picture. The general design of the transmitter was based on the fundamental principles which have now been in use for some years in commercial short-wave communication transmitters, but certain new problems were met in adapting this design to the ultra-short wave-length of 6·7 m. (frequency 45 Mc./sec.) required and also to enable it to handle the unusually great modulation bandwidth of ± 2·5 Mc./sec. The paper gives some details of the circuit, valves and assembly employed at the Alexandra Palace station.

Reverting to the first paper by Macnamara and Birkinshaw, considerable space is devoted to a general description of the London Television Station, with plans of the accommodation and details of the studios and equipment employed for the staging and production of the vision programmes radiated. For outside broadcasts, a fleet of special motor vans has been developed, these carrying respectively a mobile studio, an ultra-short wave transmitter for providing a radio link with Alexandra Palace, and a mobile power supply for the above two vehicles. In addition, a fourth vehicle is used to carry an extensible self-supporting wooden ladder of the fireman's type, to provide an aerial mast for the local mobile transmitter. Reception from this transmitter is carried out with a radio link receiver installed at Alexandra Palace, but precautions have had to be taken to secure freedom from interference from the main vision transmitter.

To avoid difficulties involved in the operation of such an ultra-short wave radio link, a balanced low-capacitance cable, primarily designed for television, has been installed between Alexandra Palace and central London, tapping points being provided at frequent intervals along the cable route at what may be considered to be the main points of interest from a television programme point of view. In addition, experiments have been conducted into the use of short lengths of ordinary telephone line whereby extensions may be made from the main television cable.

The latter portion of the paper gives the results of a field strength survey of the radiation from Alexandra Palace, and a contour map illustrates the distribution of the field at distances up to 25 miles from the station. This was the range originally estimated for, but it is now safe to say that good reception can be obtained up to about 35 miles, except in cases where unusually bad interference is encountered. Under exceptionally favourable conditions, good reception has been reported at distances of 40 to 60 miles, and while reception is still possible at much greater distances up to a few hundred miles, this usually does not come up to the standard of reliability which it is desirable to attain in a public broadcasting service.

Altogether these four papers form a useful and interesting record of the successful development and operation of what still remains the first public television service in the world. R. L. S.-R.

Association of Teachers in Technical Institutions

ANNUAL CONFERENCE AT LEEDS

THE twenty-ninth annual conference of the Association of Teachers in Technical Institutions was held in Leeds on June 4–7. A civic welcome was accorded to the delegates by the Deputy Lord Mayor of Leeds, who was supported by the Director of Education. The president for 1938–39, Mr. A. C. R. Ritchie (Gravesend), was inducted by the retiring president, Mr. W. E. Park (Luton). In his presidential address, Mr. Ritchie reiterated the Association's belief in the principle of collective security and said that in spite of the rapid deterioration in standards of international integrity, "we believe that it is not too late for the nations to get together in a sane and orderly atmosphere, so that they may work together for the common good of their people, and that the wonders of scientific discovery and inventive genius may at last be directed towards increasing human happiness instead of being prostituted to the destruction of modern civilization. After all," he asked, "what has civilization done for us if we cannot live peaceably one with another ?"

In this connexion, Mr. Ritchie referred to a remark by the Chinese Ambassador during a recent address to an international conference of teachers convened by the League of Nations Union. Arguing that "We will have to scuttle back to the humanities to save our lives, let alone ourselves," the Ambassador said, "Technical Education is now ripening to make us cave-men as its final fruit." Mr. Ritchie hoped he would not be misunderstood if he reminded the Ambassador that such a statement is scarcely fair to technical education. No one more than he sympathized with the desperate sorrows of peoples torn by war. But technical education is not necessarily responsible for those sorrows. On the contrary, it gives us possibilities of life-standards hitherto unknown. Could the Conference which His Excellency addressed have been held without the aid of technical education ? Here were representatives of many countries brought to London by all the modern forms of transport. Their words and thoughts were transmitted across space by means of inventions just as modern. Because social ideas move slowly, because a minority prostitutes the work of scientific workers and technologists, science and technology should not be blamed. If there are those who use it mischievously, it is their *ideas* which must be attacked and not the blessings of technology which must be delayed.

At the closing meeting of the Conference, Prof. H. Levy, of the Imperial College of Science and Technology, gave an address in which he sought to evaluate the part played by men of science and technologists in the present international situation. Since they have made possible the latest and most deadly means of war, he insisted that it is their duty to see where the application of their work is leading the world. They cannot, for example, shut their eyes to the experiments now being conducted in Spain and China. They have been brought up, he said, to believe that any contributions they make to scientific knowledge are to be regarded as a service to humanity. That is not true. The results of their work are at present being used to destroy humanity, and it is their duty to face up to that fact. They must learn, however, to watch such experiments as those in Spain and China unemotionally and with the same detachment as they regard an experiment in a laboratory. They must understand causes and effects, and to do that they must realize that, from man's first appearance, forces have been at work which have, at various stages in history, altered the economy under which society has been conducted. A feudal economy, for example, could not cope with new knowledge and it had to break up. The main forces which have driven man on through successive stages have been the discovery of new kinds of tools and the knowledge of new raw materials. These forces are more than ever at work. Technical men are producing a new technique. The new processes which are being discovered to control Nature are causing the stresses and strains, the wars and the revolutions which have been manifest since the end of the war in 1918. The man of science and the technologist, as individuals, can do little. But, if they see clearly what is happening and understand the significance of events and the part which their work is playing, they will discover the necessity for them to work through their groups and associations in order to save the world from disaster.

Pontifical Academy of Sciences

THE formal inaugural meeting of the second academic year of the newly reconstituted Pontifical Academy of Sciences (see NATURE, 140, 965; 1937) was held on January 30, 1938, in the presence of His Holiness Pius XI. The meeting, an account of which is contained in the Academy's *Acta* (2, Part 1, 1938), was held in the new hall which has been added to the Casina Pio IV, the Academy's headquarters in the Vatican gardens, through the generosity of the Pope. Besides a large proportion of the seventy academicians, there were present Church dignitaries and lay members of the Vatican Government, representatives of the Royal Italian Academy and of the Academy of the Lincei, and members of other Roman cultural and scientific bodies.

In his presidential address Father Gemelli, after paying tribute to the Pope's active and generous interest in the progress of science, surveyed the Academy's first year of existence. In addition to the publication of two large volumes of the

Commentationes and of the *Acta*, the Academy has instituted an inquiry among its members to determine what shall be its most useful function. The president emphasized that the Papal Academy differs from other national bodies of a similar nature in being truly international, since it contains members of many nationalities all of whom have equal rights and privileges. From the large number of replies to the president's inquiry, which are reproduced in the *Acta*, it would appear that there is a general desire that the Academy should not restrict its activities to the publication of individual scientific communications, but should take advantage of the freedom of action guaranteed by its scientific independence of race or creed to strengthen the bonds between the various sciences. The rules of the Academy have been the subject of further discussion by its council and members, and steps have been taken to ensure that in the election to vacancies in the membership the international character and the representation of the different sciences shall be maintained.

An annual prize, of the value of 25,000 lire, to be known as the Pius XI Prize, has been instituted. It may be awarded for any distinguished contribution to the progress of science made in the preceding ten years, either by a single important discovery or as a result of a series of systematic researches, or by a publication of great scientific interest. The president announced that the members of the Academy would shortly be called on to propose names for the 1938 award, which will be made for a distinguished contribution to the progress of biological science.

During the first year of its existence, the new Papal Academy has suffered the loss by death of three of its members, namely, Lord Rutherford, Paolo Luigioni, and the Marchese Marconi, and the main purpose of the inaugural meeting was to honour the memory of the last-named of these distinguished men of science. The Marchesa Marconi was present as an honoured guest at the ceremony. Guglielmo Marconi's immense contributions to physical science and to the development of wireless communication through space formed the subject of addresses by Prof. G. C. Vallauri of Turin, and Prof. W. F. Bjerknes of Oslo, both members of the Papal Academy. The latter, who is probably the sole surviving personal pupil of Heinrich Hertz, exhibited during his discourse the original 19-page manuscript entitled "Über elektrodynamische Wellen im Luftraume und deren Reflexion" in which Hertz described the first results of his experiments on electric waves. At the close of Prof. Bjerknes' address, Hertz's manuscript was examined by His Holiness with considerable interest. As was reported in *The Times* of March 26, 1938, the Pope's interest in this document (which was not, as reported there, presented by Prof. Bjerknes to the Papal Academy) found a practical expression in the personal gift of a sum of £250 to Hertz's widow, Mrs. Elizabeth Hertz, who is living in exile at Cambridge with her two daughters. The presentation of the gift was entrusted to Canon Marshall, of Cambridge, by Cardinal Hinsley, Archbishop of Westminster.

Pius XI, in his own address to the Academy, paid a personal tribute to the benefits conferred on mankind by the labours of Hertz and of Marconi, whose work, undoubtedly accompanied by Divine blessing, recalled the words of Schiller: "Soll das Werk den Meister loben, doch der Segen kommt von oben". The Pope also referred to his own deep-rooted interest in science and the search after truth—an interest which had in his own private life found an outlet in the love of Nature and a passion for the reading of books.

Oil from Coal

In the December 1937 issue of the *New Zealand Journal of Science and Technology* (19, No. 7), there is an interesting article, initialed "W. G. H.," on the production of oil from coal as seen from an Australian point of view.

The process of low-temperature carbonization is dependent for commercial success largely upon the acquisition of a market for the semi-coke produced. Such a market is readily found in Great Britain, where the smoke nuisance from raw coal burned in the domestic grate is acute. In Australia, however, very little raw coal is burned in the cities and there is consequently no market for semi-coke in this direction. Low-temperature carbonization might be considered as a subsidiary method of providing coke for the Fischer Tropsch process of synthesis of hydrocarbons or to provide coke for hydrogenation.

Economically, hydrogenation is unsound from the Australian point of view. The estimated cost of a plant capable of producing 45,000,000 gallons of petrol per annum from bituminous coal is approximately £11,000,000 (Australian currency) and for one working on lignite it is nearly £12,000,000. Allowing for a return on capital of 6 per cent and for amortization in ten years, the cost would be 17*s*. 3*d*. per gallon from bituminous coal and 18*s*. 2*d*. per gallon from lignite. The Fischer Tropsch process is no more attractive economically than hydrogenation in Australia. It has been estimated that to produce petrol at 8*d*. per gallon from a plant with an output of 9,000,000 gallons per annum, a subsidy of £300,000 or £1,000 per man per annum would be required.

The above facts admittedly do not commend any of these processes in Australia, but there are other important factors which would have to be carefully considered before deciding whether or not to erect a coal conversion plant in the Commonwealth. The chief of these are future supplies and cost of flow oil; payment in Australian goods for foreign supplies; possible interruption of supplies in the event of war; storage problems; the likelihood of finding flow oil in the Commonwealth; and the value of a new industry as an employer of both direct and indirect labour.

All these contingencies must be assessed before any decision is taken to erect a plant which at best can only produce a local product to compete with an imported article at one third to one quarter of the cost.

Science News a Century Ago

Philip Kelland appointed to Edinburgh

ON June 20, 1838, *The Times* announced that Mr. Kelland had been appointed to the chair of mathematics in the University of Edinburgh. The vacancy had been caused through the resignation on account of ill-health of Prof. William Wallace (1768–1843), who had held the chair since 1819. Kelland was the son of a clergyman and was born at Dunster, Somerset, in 1808. Entering Queens' College, Cambridge, he graduated in 1834 as senior wrangler and Smith's Prizeman, and for three years was a tutor. He held the professorship at Edinburgh until his death on May 7, 1879. Among his writings were a "Theory of Heat", papers on the motion of waves, the article on algebra in the ninth edition of the "Encyclopædia Britannica" and an introduction to quaternions. At the time of his death he was president of the Royal Society of Edinburgh. As a teacher he was unequalled.

Wheatstone and the Stereoscope

THE meeting of the Royal Society held on June 21, 1838, was the last before the long vacation. One of the papers was by Whewell on tides, and another was by Wheatstone entitled "Contributions to the Physiology of Vision. Part I. On some remarkable and hitherto unobserved Phenomena of Binocular Vision". In his paper, Wheatstone showed that the perspective projections of an object upon the two retinæ differ according to the distance at which the object is placed before the eyes; if it be placed so distant that to view it the optic axes must be parallel, the two projections are precisely similar, but if it be placed so near that to regard it the optic axes must converge, a different perspective projection is presented to each eye, and these perspectives become more dissimilar as the convergence of the optic axes becomes greater. Notwithstanding this dissimilarity between the two pictures, which is in some cases very great, the object is still seen single, contrary to the very prevalent metaphysical opinion that the single appearance of objects seen by both eyes is owing to their features falling on corresponding points of the two retinæ. To illustrate some of his views, Wheatstone used an apparatus called by him a stereoscope.

The Newcastle and Carlisle Railway

AMONG the British railways opened in 1838 was that from Newcastle to Carlisle, a distance of sixty-one miles, which was inaugurated with much ceremony on June 18. Describing the event, the *Tyne Mercury* said: "The anniversary of the battle of Waterloo, which crowned the British arms with success and restored peace to Europe, was selected as the day on which to celebrate the event, and one of the engines is named *Wellington*. Different portions of the railway have been opened from time to time, and made available for the commerce of the north; but on Monday the whole line was passed over for the first time. The engines started in the following order:—First the *Rapid*, as an advanced guard and without any train, displaying the Union Jack, next the *Meteor* with four carriages and a flag on which was inscribed 'England expects every man to do his duty'. In this train we observed the mayor of Newcastle and his friends with the Allenheads band; then followed the *Victoria* with nine carriages, the *Wellington* with nine, the *Nelson* with seven, the *Lightning* with ten and the Carlisle band; next the *Tyne* with its steam organ and nine carriages; after these came the *Carlisle* with eight, the *Eden* with ten, the *Goliath* with nineteen and about 600 passengers, then the *Atlas* with seventeen, next the *Samson* with eleven. . . . The *Newcastle* with nine . . . followed by the *Hercules*, the last of the list, with eight carriages." The *Tyne Mercury* estimated that the trains carried more than 3,500 passengers, and the procession when in motion extended over one and a half miles.

Disease Among Troops in West Indies

IN a paper read before the Statistical Society on June 18, 1838, and published in the *Athenæum* of June 30, on the sickness and mortality among the troops in the West Indies, Mr. Henry Marshall, deputy inspector-general of hospitals, and Captain Tulloch came to the conclusion that many of the opinions hitherto entertained of the nature and influence of the causes of diseases in the West Indies must have been adopted on inadequate evidence, since it appeared that no uniform effects were produced by exposure to a high temperature, by excess of moisture, by the combined effects of high temperature and great moisture, by the absence of trade winds during the sickly season, by the supposed influence of miasma from the South American continent, or by the physical and geographical character of the soil. In the absence of all tenable and consistent theories to account for the high mortality of the white troops in the West Indies, the suggestion was made that experiments should be undertaken on the electrical condition of the atmosphere during epidemic periods, the development of electrical phenomena being known to be intimately connected with heat and moisture, and to exercise an influence on vegetation.

Electric and Crystalline Polarity

FARADAY's first entry in his Diary for June 21, 1838, is: "Experimented on the effect of Polar arrangement of the particles of crystals on their specific inductive capacity, i.e., on their inductive capacity in different directions." The work thus begun evidently occupied him for the greater part of the summer, for the entries continue until August 14. The apparatus used was simple. Cubes of various crystalline materials, for example, Iceland spar and rock crystal, were cut with their faces parallel and perpendicular to the crystal axes. The cube under experiment was placed on a stand, and a brass ball, connected to a Leyden battery by which it was kept uniformly electrified, brought up to one face. The induction through the crystal was measured by means of a Coulomb torsion electrometer, the carrier ball of which was brought up to the opposite face.

A large number of measurements of the inductive capacity of the materials was made in directions parallel to and transverse to the crystalline axis, in the hope of detecting some difference. The experiments were afterwards described in the Fourteenth Series of the "Experimental Researches in Electricity", and although Faraday says that he "sought with great anxiety for a relation between electric polarity and that of crystallization", he came reluctantly to the conclusion that his results had "not established any connection of the kind sought for".

Retirement of Olinthus Gregory

In its issue of June 23, 1838, the *Mechanics' Magazine* said: "We understand that Dr. Olinthus Gregory, who has for the long period of thirty-five years presided over the Royal Military Academy, Woolwich, with so much credit to himself and advantage to the public service, and whose numerous scientific works have contributed so much to the promotion of practical science, has been permitted to retire from the Professorship of Mathematics at Woolwich. He is succeeded in the professorship by Mr. S. H. Christie, Secretary to the Royal Society who took a high degree at Cambridge many years ago, and who has been connected with the Royal Military Academy, we believe, about 32 years."

Olinthus Gilbert Gregory (1774–1841), who was born in Huntingdonshire of humble parentage, owed his early training in mathematics to the Leicestershire botanist, Richard Weston (1733–1806). He was in turn sub-editor of a newspaper, a bookseller and a private teacher. Becoming known to Charles Hutton, the professor of mathematics at Woolwich, and the editor of the *Ladies' Diary*, in 1802 he was made a master in the Royal Military Academy and in 1807 succeeded to Hutton's chair. Among his contributions to science were his experiments on the velocity of sound. He was one of the projectors of University College, London, and his name was inscribed on the stone laid in Gower Street on April 30, 1827.

University Events

BIRMINGHAM.—The new Hospital Centre and Medical School are to be opened by the King and Queen on July 14, and to mark the occasion, at the degree congregation on July 2, the honorary degree of LL.D. is to be conferred on the following: Viscount Nuffield, who has contributed nearly £200,000 to the Hospital Centre; Mr. Harry Vincent, who besides being a generous supporter has given much time and energy to the working out of the scheme; Colonel Sir Bertram Ford, chairman of the Board of Management of the Birmingham Hospitals Contributory Association; Dr. Robert Hutchison, president of the Royal College of Physicians; Sir Cuthbert Wallace, president of the Royal College of Surgeons; and Sir Edward Mellanby, secretary to the Medical Research Council.

CAMBRIDGE.—Prof. Eileen Power, professor of economic history in the University of London, has been elected to an honorary fellowship at Girton College.

OXFORD.—In Convocation on June 14, it was agreed to confer the honorary degree of D.Sc. on Prof. C. G. Jung, professor of psychology at the Federal Technical University, Zurich, on July 30.

C. G. T. Morison, Christ Church, has been elected a member of the Hebdomadal Council.

H. B. Butler, All Souls College, has been appointed the first warden of Nuffield College.

SHEFFIELD.—Prof. Irvine Masson, professor of chemistry and head of the Department of Pure Science in the University of Durham, has been appointed vice-chancellor in succession to Dr. A. W. Pickard-Cambridge, who is retiring.

Dr. E. Leighton Yates has been appointed assistant lecturer in physics.

Societies and Academies

Dublin

Royal Irish Academy, May 23.

J. K. CHARLESWORTH: Some observations on the glacial geology of north-east Ireland. The chief theses of this paper are (1) the drumlins of north-east Ireland were fashioned by ice of the last main glaciation; (2) a Carlingford re-advance against the Mourne and Carlingford Mountains and along Carlingford Lough; (3) the southward retreat of the ice along the Main and Lower Bann and its stagnation along its front and in the Lough Neagh area; (4) an Antrim coastal re-advance that blocked the Bann and Lagan and ponded the drainage of the glens of Antrim in a suite of glacier-lakes.

H. S. W. MASSEY and R. A. BUCKINGHAM: Long-range forces between hydrogen molecules. The van der Waals' force between two hydrogen molecules in any fixed orientation is calculated.

Paris

Academy of Sciences, April 20 (*C.R.*, 206, 1209–1228).

LUCIEN DANIEL: Sudden or retarded ripening in the bean.

ANDRÉ HAARBLEICHER: The triangles of Poncelet.

MLLE. MARGUERITE QUINTIN: The hydrolysis of solutions of cadmium benzenesulphonate.

ANDRÉ MERCIER and TORSTEN GUSTAFSON: The true energy of the electron.

SERGE NIKITINE: Contribution to the theory of photodichroism.

HÉLIOS SCAETTA: The notion of a cycle in the evolution of tropical soil based on researches in central and in western Africa.

MME. RITA DUBERTRET, LOUIS DONCIEUX and LOUIS DUBERTRET: The Nummulitic of Koseir, to the south of Antioch (Syria).

VLADIMIR FROLOW: The annual component of the rains in Morocco.

April 25 (*C.R.*, 206, 1229–1272).

LUCIEN CAYEUX: The migration of phosphoric acid, following on the decalcification of the phosphatic chalks with *Belemnitella quadrata* in the north of France. The genesis of the phosphatic chalks and of the sands arising from their decalcification results from two totally different phenomena, an incomplete calcification causing an enrichment of the product and an addition of phosphate to the limestone which escaped solution.

ANDRÉ BLONDEL: An apparatus for comparing the luminous flux of sources of light.

GEORGES GIRAUD: Problems of the Dirichlet type.

JULES HAAG: Asymptotic formulæ concerning the oscillations of relaxation.

HENRI LAGATU and LOUIS MAUME: Measurements of agricultural biochemistry on the branches of the vine.

PAUL LÉVY: The definition of the laws of probability by their projections.

CHRISTIAN PAUC: Unification of the generator processes of various contingents and paratingents.

AYZYK GORNY: The maxima of the moduli of a function and of its derivatives.

JEAN MARIANI: A possible interpretation of the solar and terrestrial magnetic fields.

RAYMOND CHEVALLIER and MLLE. SUZANNE MATHIEU: Adsorption in the precipitation of hydroxide starting with ferric sulphate.

ANDRÉ MICHEL and MLLE. MARGUERITE GALLISSOT: The relation between the state of crystallization and the amplitude of the thermomagnetic anomaly of lepidocrocite.

MAURICE BAYEN: The measurement of the ultra-violet dispersion of water at temperatures between 6° and 35° C.

FRÉDÉRIC JOLIOT and IGNACE ZLOTOWSKI: The formation of an isotope ^{5}He during collisions between helions and deuterons. Description of experiments demonstrating the formation of the helium nucleus of mass 5·0106, stable towards the emission of a neutron.

ALBERT KIRRMANN and JEAN LICHTENBERGER: The structure of some halogen substituted aldehydes and of a methoxyl derivative.

V. M. MITCHOVITCH: The constitution of the quinaldinic acids.

MARTIN BATTEGAY and ROBERT KREBS: The thiolcarbamic esters (alkyl-S-thiourethanes) and their transformations into halides of alkylsulphonic acids.

EDOUARD LEGÉ: The transformation of oleaginous materials into mixtures of hydrocarbons.

ANDRÉ EICHHORN: Chromosomic enumeration and nuclear evolution in two *Tetrastigma* (Ampelidaceæ).

ANDRÉ KLING, NICOLAS SAMSSONOW and MME. MARGUERITE HEROS: Primitive cancers of the lung produced in mice by light oils from coal tar.

Vienna

Academy of Sciences, February 17.

H. LICHTBLAU: Anomalies occurring in mass spectroscopy. On plates taken with the mass spectrograph of Mattauch and Herzog certain lines and bands are found which do not correspond with any ions. The origin of these 'ghost' lines is investigated.

K. PRZIBRAM: Coloration and excitation of fluorite and a new fluorescent material containing divalent europium. Europium oxalate fused with calcium chloride yields a fluorescent material with the colour of Weardale fluorite. A study of this suggests that all fluorites contain traces of divalent europium. Various degrees of partial reduction of the calcium ions by the europium correspond with the various colours found in Nature.

H. GÜNTERT: New Clariide from the Cameroons.

H. PRZIBRAM: Biochemistry of the antipathic substances in the anterior and posterior lobes of the hypophysis. The anterior lobe is found to contain adrenalin and the posterior lobe choline. Various commercial preparations of extracts of the hypophysis are also examined.

R. SCHUMANN: Latitude variations in 1936 and 1937. It is necessary to establish latitude measuring stations in high latitudes if reliable measurements of movements of the poles are to be made.

F. KERNER-MARILAUN: Influence of melted snow on the temperature of mountain springs. Measurements of the difference in temperature between spring waters and the ground, when correlated with the amount of snowfall in the neighbourhood, enable the course of the water from the melting snow to be traced through the rocks to the springs.

V. F. HESS, A. DEMMELMAIR and R. STEINMAURER: Relation between the intensity of the earth's magnetic field and cosmic rays.

O. AMPFERER: Tectonic conception of dead folds. Elimination of dead folds and formation of folds from unfolded layers.

February 24.

M. TOPERCZER: (1) Secular variation of the magnetic declination in Austria in the period 1930–1935. (2) The great magnetic storm on the occasion of the aurora of January 25, 1938.

March 3.

J. HOFFMANN: Permanganate ions in violet and reddish apatites. The colours of certain apatites are due to MnO_4 ions. The colour changes which occur on heating, irradiation, etc., are analogous to those which occur in 'chameleon mineral'.

A. KAILAN: Chemical action of radium radiation (21). Action on piperidine and quinoline.

H. HABERLANDT: Luminescence, absorption and arc spectra of fluorites and apatites.

F. E. SUESS: Formation of the Caledonians and Wegener's hypothesis.

E. SPÄTH and P. H. LÖWY: Cumarine-α-pyrone.

K. M. KREMANN and E. GASTINGER: Degree of depolarization of the scattered radiation of binary liquid mixtures.

M. PESTEMER, A. J. K. SCHMIDT, LOTTE SCHMIDT-WILIGUT and F. MANCHEN: Halochromism of perylene, its quinones and some of its substitution products.

H. TOLLNER: Aurora of January 25, 1938. The Zentralanstalt fur Meteorologie und Geodynamik in Vienna has received 672 reports of observations of the aurora in Austria and neighbouring States. These are available for any men of science who may wish to study them.

March 10.

O. AMPFERER: Conception of tectonic leading lines.

D. V. KRIPP: Method for the measurement and graphical representation of organic systems.

Tokyo

Imperial Academy (*Proc.*, 14, No. 3, 87–124, March 1938).

SHIN-ICHI TAKAHASHI: An application of the Fourier transform to almost periodic functions.

KINJIRO KUNUGUI: On the projection of an ensemble plane *G* 8.

TOSIO KITAGAWA: Multiplication theorems of the Cauchy series.

HISASHI KIMURA: New observing programme for the International Latitude Service.

SHIGEO NAKAGAWA and INOSUKE SUMOTO: γ-Ray activity induced in cadmium by slow neutron bombardment.

AKITUNE IMAMURA: Crustal deformations as revealed through revisions of levels linking Hirosima with Sindi.

YASUHIKO ASAHINA and TUTOMU MOMOSE: A santonin derivative with immediate vermifugal action.

SHINKICHI YOSHIMURA and TOSIO WADA: Hydrogen sulphide and ferrous sulphide in the bottom deposits of the brackish water lake, Hamanako, Sizuoka Prefecture. The hydrogen sulphide in the black shale deposits determines the absence or poverty in population of fossils.

TEÜCHI KOBAYASHI: A tectonic view on the Öga Decke in the inner zone of western Japan.

Forthcoming Events

Wednesday, June 22

SOCIETY FOR THE STUDY OF ALCHEMY AND EARLY CHEMISTRY (at King's College, Strand, London, W.C.2), at 7.30.—Dorothea W. Singer: "The Name of Plato in Chemistry".

INTERNATIONAL ENGINEERING CONGRESS, June 21–22, to be held at the Empire Exhibition, Glasgow.

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES, June 21–25.—Annual Congress to be held at Worthing.

June 21, at 8.—Dr. Julian Huxley, F.R.S.: "Natural History—Taxonomy and General Biology" (Presidential Address).

Friday, June 24

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. John Beattie: Recent Work in Experimental Surgery" (Arris and Gale Lectures. Succeeding lectures on June 27 and 29.)

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

DISTRICT FOREST OFFICERS and DISTRICT ESTATE OFFICERS to H.M. Forestry Commissioners—The Secretary, Forestry Commission, 9 Savile Row, London, W.1 (June 20).

ASSISTANT LECTURER IN ORGANIC CHEMISTRY and ASSISTANT LECTURER IN GEOLOGY in the University of Bristol—The Registrar (June 21).

PRINCIPAL of the Smithfield Meat Trades Institute, E.C.1—The Education Officer (T.1), County Hall, London, S E.1 (June 25)

LECTURER IN ELECTRICAL ENGINEERING in the Denbighshire Technical Institute, Wrexham—The Director of Education, Education Offices, Ruthin (June 25).

LECTURER IN MATHEMATICS in the Bedford College for Women, Regent's Park, London, N.W.1—The Secretary (June 30).

LECTURER IN ENGINEERING (Strength of Materials) and TWO LECTURERS IN ELECTRICAL ENGINEERING in the Technical College, Derby—The Clerk to the Governors (June 30).

SENIOR LECTURER IN ELECTRICAL ENGINEERING in the County Technical College, Mansfield—The Principal.

BOTANIST in the Plant and Animal Products Department of the Imperial Institute—The Establishment Officer, Imperial Institute, London, S.W.7.

Prehistory in South Africa

IN a letter appearing in a recent issue of NATURE (June 4, p. 1010) Sir Arthur Keith, commenting on the significance of the Florisbad skull for the study of the origins and distribution of early racial types and its place in the African series of primitive forms of man, drew a remarkable, and at first sight startling, conclusion from a recent examination of a cast of the skull. Pointing, in full agreement, to the anatomical analysis by Dr. Alex. Galloway of the characters of the Florisbad find, from which it appears that Neanderthaloid characteristics are here found accompanying features such as occur in the Boskop skull—a 'modern' type, which Sir Arthur regards as proto-Bushman—he goes on to suggest that not only is Florisbad man a transitional form from Rhodesian man to Boskop man, as Dr. Galloway maintains, but also that he heralds the modern Hottentot and Bushman races of South Africa. The skull is, he says, "a mosaic of Rhodesian, Boskop and Bush characters".

Hence it would appear that Sir Arthur finds in the Florisbad skull a link in the chain of evidence for the theory of the continental evolution of modern racial types, which he put forward some two years ago (see NATURE, 138, 194; Aug. 1, 1936), and for which he then sought support in the Mongoloid appearances which Prof. F. Weidenreich had detected in the teeth and jaws (and later found in the form of the nose) of Peking man.

It may not be out of place to note in this connexion that even Rhodesian man in certain characters shows an approach to the modern type, in contrast with the primitive facial skeleton—a contrast which moved the late Sir Grafton Elliot Smith to say at first sight that apparently the face was the latest feature to be affected by the evolutionary process. It will be remarked, however, that in the Florisbad skull it is the face, and more especially the forehead, in which the approach to the 'modern' is most marked.

Sir Arthur Keith's letter in NATURE, to which reference is made above, should be read in conjunction with the reference to the Florisbad find made by Mr. A. J. H. Goodwin in the course of a survey of recent advances in South African prehistory, which appears in the current issue of *Scientia* (iii), 32, 1–6; 1938). Mr. Goodwin there points out that the Florisbad skull, which was found in association with extinct animal forms and stone implements by Dr. T. F. Dreyer in 1935 and has been studied by Prof. M. R. Drennan and others, after reconstruction, is the first specimen of a human skull from Africa which may be said to show true Neanderthal characteristics, if *H. Rhodesiensis* be excluded. A further point of importance and great interest, in view of Sir Arthur Keith's conclusions, to which he also refers, is the possibility of a relationship with Prof. Broom's Korana type and the Cape Flats skull. The significance of this will be appreciated if reference be made to the account of the physical characters and culture of the inhabitants of the Oakhurst rock-shelter (see p. 1146 and p. 1151), in which Prof. Drennan finds Hottentot characteristics in the skeletal remains of a people definitely not, or perhaps it should be said not yet, Hottentot in culture. We appear here to be getting very near a chain of positive evidence, with collateral support, for Sir Arthur Keith's independent suggestion that the Florisbad skull, as a transition from the Rhodesian skull to the Boskop type, heralds the modern Hottentot and Bushman races of South Africa.

A further link in the chain of argument is supplied by an account by Sir Arthur Smith Woodward of a fossil skull of an ancestral Bushman, found on the foreshore of the Blue Nile at Singa, about two hundred miles south of Khartoum (*Antiquity*, June 1938). He points out that this find is of great interest in view of the fact that it is now recognized that during the Pleistocene, and even during a later prehistoric period, there were in northern Africa human races related to the existing Bushman and the Hottentots of the south; while the shape of the skull in some of the early Egyptians suggests relationship to the Bushman.

This specimen was found in February 1924, by Mr. W. G. R. Bond, then governor of the Fung Province of the Anglo-Egyptian Sudan. It was embedded in a limestone concretion, a few feet above low-river level. It is still partly embedded in the hard matrix, but it has been cleaned enough to exhibit its principal characteristics.

Without entering into the detailed description of the skull given by Sir Arthur, his main conclusions may be mentioned. The skull, it is said, is shorter and wider than the ordinary skulls of Bushmen, but its proportions are not very different from those of a few exceptional examples. It resembles the Bushman, first in the fullness of the frontal region and the slight longitudinal keel in its upper part; secondly, in the flattening of the middle part of the cranial roof; and thirdly, in the prominence of the large parietal bosses and the medium longitudinal depression between them. Other resemblances need not detain us; but the differences are no less important from the point of view with which we are here concerned. For this Singa skull differs from the Bushman in the greater prominence of the supraorbital ridges and in the forward curve of the nasal bones, which indicate a less shortened facial region. It may indeed, Sir Arthur concludes, be regarded as belonging to an ancestral Bushman type, in which the face has not yet shrunken. It is, therefore, especially significant that although Sir Arthur considers that this skull differs from all human skulls hitherto described as found fossil in North Africa, it presents certain resemblances with the skulls found at Afalou-bou-Rhummel in Algeria by Dr. C. Arambourg; but, it is added, in its most important features it agrees still more closely with the Boskop skull, of which it appears to be a brachycephalic variant. The modern Bushman, says Sir Arthur, summing up, may be regarded as a degenerate localized type, with shortened face and protuberant brain-case, of a normal-sized vigorous race, once distributed widely in Africa.

To return to the Florisbad skull. Its special interest for the prehistorian lies in the precision with which it can be assigned to a cultural setting. The stone implements, which were found with the skull, of indurated shale, belong to the Middle Stone Age of South Africa. There is present in them, Mr. Goodwin points out, a very clear Mousterian tradition. The most typical form is a flat long, triangular point, showing convergent flaking and a faceted butt. With this are later types, backed blades, parallel flakes and so on. Burins also occur. The culture is, in fact, a typical variant of the South African Middle Stone Age.

The special significance of the find in this relation is, as Mr. Goodwin goes on to indicate, that the discovery of Neanderthaloid characteristics in the skull in association with implements bearing Mousterian stigmata in South Africa is new. Hitherto, the skulls which have been found in certain association with implements of this general group have all belonged to the type of *H. sapiens*; but, he adds, until the chronological relationship between the Florisbad site and other Middle Stone Age deposits has been the subject of more detailed work, it is unfair to draw further conclusions. It may, however, be added that in the survey of the Vaal River gravels, which has been carried out by Dr. R. van Riet Lowe, as summarized by Mr. Goodwin, the Middle Stone Age is associated with the Third Wet Phase after the deposition of the youngest gravels, this being the third and latest of the three series of deposits which have been described. It is, however, significant that in South Africa the Middle Stone Age, though it has its origins in the Mousterian, would appear to have lasted considerably longer than in its European variant, and as it develops shows increasing influence of Upper Palæolithic type. The Later Stone Age diverges still further from any European cultures, and may best be related to the Capsian and later cultures of North Africa.

Lastly, to complete the picture, it may be mentioned that the Oakhurst Rock Shelter (see p. 1151) presents a full history of the local facies of the Later Stone Age, ranging, after the temporary use of the shelter, from Smithfield *B* cultures to the latest forms in a developed Wilton, the closing phase of Old Stone Age.

Life Work of Elliot Smith

Sir Grafton Elliot Smith: a Biographical Record by his Colleagues. Edited by Warren R. Dawson. Pp. 272 + 3 plates. (London: Jonathan Cape, Ltd., 1938.) 12*s.* 6*d.* net.

To Grafton Elliot Smith the pious hands of friends and colleagues have erected in this book "a monument more lasting than brass". A biographical sketch by Mr. Warren Dawson—based largely on letters written by Elliot Smith himself (for he preserved few or none addressed to him), two autobiographical fragments, of which the writing was interrupted by his death, and an account of his Cambridge days, also unfinished owing to the death of its author, Lord Rutherford, are followed by chapters, each contributed by someone most intimately in touch with him in a particular phase of his life or work.

After the period of formal education and training in Australia and at Cambridge, which closed with the acceptance of a professorial chair at Cairo in 1900, Elliot Smith's career, broadly speaking, was marked off into three phases: his work in Egypt from 1900 until 1909, of which an account supplementary to that of the main narrative, and dealing more particularly with his work in the Archæological Survey of Nubia, is given by Prof. F. Wood-Jones; secondly, his tenure of the chair of anatomy at Manchester from 1909 until 1919, which is recorded by Prof. J. S. B. Stopford; while Prof. H. A. Harris tells the story of the third period and the great work he carried out in the reorganization of his department at University College as professor of anatomy in the University of London from 1919 until the end. Prof. J. T. Wilson, formerly of Sydney, tells us of his early work as student and research worker, Dr. A. J. E. Cave surveys his contribution to knowledge in anatomy and neurology, and Dr. W. J. Perry, who was perhaps closest to him in the later part of his life, reviews his contribution to ethnological theory in the doctrine of the diffusion of culture and the origin of civilization in ancient Egypt.

The account of Elliot Smith's life and work given here is expository and descriptive rather than critical. The opposition with which his views on the diffusion of culture were greeted receives frequent mention; but no attempt is made to estimate how far, if at all, it was valid. It is treated throughout as negligible—a mere fluttering in academic dovecotes.

Apart from this weakness—and it is undoubtedly a weakness—this biography is a worthy tribute to a great man; and for once the eulogy of friends has drawn no distorted portrait. His loyalty to his friends was never failing and was repaid by a like devotion and understanding. Elliot Smith's one great failing, however, was an extreme sensitiveness to criticism, which reacted in a trenchant retort, too little apprehensive of a like sensitiveness in others. It veiled from many the essential kindliness, generosity and honesty that lay behind it all. It helped to obscure in the eyes of opponents the fact that Elliot Smith's work on both the physical and the cultural side of the study of man was essentially a logical and philosophic unity. His excursions into the cultural field, whatever their failings, were not merely the eccentric aberrations of genius, as many regarded them. It was this synthetic quality of his mind which led him, when at the close of the Great War he was deeply impressed by the significance of psychology, to formulate his conception of the study of man as a scheme of 'human biology'.

When Elliot Smith went from Australia to Cambridge, he was already well on the way to establishing a reputation as research worker and original thinker; but his appointment to the chair at Cairo was to exercise a decisive influence on his career. Within a very short time after this appointment his comparative studies of the mammalian brain had secured him a position of widely recognized authority. This he would have achieved in any environment which made research at all possible; but Egypt gave him something which he could have attained nowhere else. His examination of the technique of mummification and of the skeletal material brought to light in the archæological survey of Nubia, material extending over a prolonged period of time, gave him a new perspective in the investigation of the problems of human physical and cultural development. He was led in two directions: on one side are his contributions to palæopathology based upon the study of the evidence of disease, etc., in the skeletal remains of the ancient Egyptians, work continued by Prof. Wood-Jones; and on the other his analysis of the physical characters of the early population of Egypt, in which he detected the infiltration of a new race, the 'Armenoids', to whom he attributed the introduction of copper, with consequences in cultural development, upon which he enlarged in "The Ancient Egyptians" (1911).

This book many have considered contained some of his most original work in an all-round sense. W. H. R. Rivers, a few weeks after he himself had put before the anthropologists from the presidential chair of Section H at the Portsmouth meeting of the British Association analogous views on cultural development in the Pacific, wrote in a private letter that he had just read this book and was "wildly excited about it". Subsequent developments have perhaps tended to obscure the essential merits of a brilliant piece of research in racial analysis and history.

While these ideas concerning the racial history of the Mediterranean peoples and the cultures with which they were associated were incubating, Elliot Smith was no less busily engaged on his study of the development of the human brain, of which he gave the result to the world in his presidential address to the anthropological section at the Dundee meeting of the British Association in 1912. Possibly it would be no unfair judgment to say that it was at this point that Elliot Smith's work began to come to its full fruition. His correlation of the development of the brain and the acquisition of stereoscopic vision with the bodily modification and functional expansion, which made possible man's development in culture, are fundamental in all later studies of the course of human evolution; while his contributions to discussion of the specimens of early man which were discovered from time to time—Piltdown man, Rhodesian man, the London skull, *Australopithecus*, and above all Peking man, gave his views unquestioned authority. He was universally accepted as joint arbiter with Sir Arthur Keith on any and every skeletal fragment of early man in whatsoever quarter of the globe it might be found.

Such, in brief outline, are the salient features in a career in which Elliot Smith raised himself to an outstanding position among men of science of our time—a position in which his intellectual influence made itself felt far outside academic circles. It was in a measure the triumph of a personality, which impressed in one sense or another all who came into contact with him, and of which the essential qualities and their effect on his immediate circle may be gauged from the revealing volume for which we are indebted to Mr. Dawson and his collaborators.

Genetics of Developmental Processes

Physiological Genetics
By Prof. Richard Goldschmidt. (McGraw-Hill Publications in the Zoological Sciences.) Pp. ix + 375. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 24*s*.

PROF. GOLDSCHMIDT'S "Physiologische Theorie der Vererbung" was familiar to all serious students of genetics, and they will welcome the present book, in which the same ideas are developed in view of the last ten years' work of the author and others. The University of Berkeley, California, is fortunate in having been able to add Prof. Goldschmidt to its already world-famous school of genetics, and English students of genetics will be grateful for this book in their own language.

As an account of the genetics of developmental processes, it will prove indispensable. Among the most fascinating topics dealt with are the author's own work on the development of the wings in the 'vestigial' and 'truncate' series of allelomorphs in *Drosophila*, where the wing is normal in its early development, and lysis sets in later on, sometimes only after pupation. Sueffert found that the 'tails' on the wings of *Papilio podalirius* were produced by a similar process, which in some related species is gene-controlled. Equally interesting is Kühn's analysis, by genetical and physiological methods, of the determination of the wing pattern in *Ephestia kühniella*, and those of Zeleny, Hersh, Harnly, Plunkett and others on the temperature co-efficients of growth-rates in mutant forms.

While this book covers such topics as these very fully, it is somewhat deficient on the purely physiological side. It is startling that the name of Garrod is not even mentioned, although he was the first to show the importance of genetics for human physiology by his classical studies on alcaptonuria. Also the work of Beadle and Ephrussi on the precursors of the eye pigments in *Drosophila* is perhaps given less complete treatment than it deserves. This may be a matter of temperament. It is good, with Goldschmidt and Henke, to trace the path in the organism of an unidentified gene-controlled substance. It is better, with Beadle and Ephrussi, to be able to transfer it from one organism to another. But it is still better, perhaps, to obtain it in pure crystalline form, and to say, with Scott-Moncrieff or Penrose, that a particular gene is responsible for inserting a hydroxyl group at a particular point on the molecule. That at least is the reviewer's point of view. But it may well be that had Goldschmidt adopted it he would never have arrived at his extremely fruitful theory of the genic control of growth-rates.

Yet a more physiological outlook might have restrained the author from the rather revolutionary conclusions of the last chapter. Until recently he supported the view that different allelomorphs in the same locus merely differed quantitatively in the amount of gene substance which they contained. He has now reacted violently from this over-simple theory, and holds that there is no such thing as a normal, or wild type, gene. The chromosome is a physiological whole, and genes are merely steric re-arrangements of parts of it, altering its functions in various ways.

This is a natural reaction from the theory that the genes could be legitimately represented as points without parts of magnitude on a line. This was obviously a crude approximation to the truth. But it may still be very useful. It is just such work as Garrod's which, to the reviewer, seems to lead up to a truly physiological theory of the gene as an elementary organ with a definite function, and located in a definite region of a chromosome. The functions of the normal genes are concerned with those phases of intermediary metabolism which are upset in the mutants. On this view there is nothing strange in the possibility that two genes may overlap spatially, as for example the digestive and endocrine functions of the pancreas do. Nor is it surprising that a gene transplanted by a translocation may alter its function, as, for example, a pancreas discharging its juice to the outside through a fistula loses its digestive but not its endocrine function, or an ovary transplanted to a rabbit's ear secretes hormones of a male type. It may be that Goldschmidt has gone a little too far in his reaction from a crudely mechanistic gene theory. Mechanistic theories are not wholly true, but they are partly so; and the statement that an organism or a chromosome is a whole is no compensation for a lack of knowledge of its parts. Nevertheless, it is valuable that the case against the existence of wild type genes should be put so strongly as Goldschmidt has put it, if only to stimulate discussion.

I have only noticed one error in the book, where on p. 24, the fluid in the blebs of abnormal mouse embryos is said to be an extravasate. On the other hand, there are a number of passages in which the author does not use the normal English idiom, and where a revision would have been desirable. But these minor defects will not prevent geneticists from buying a book which is unique as a guide to the literature and stimulating even where it is perverse.

J. B. S. Haldane.

Sound Waves

Sound Waves, their Shape and Speed:
a Description of the Phonodeik and its Applications and a Report on a Series of Investigations made at Sandy Hook Proving Ground. By Prof. Dayton Clarence Miller. Pp. xi + 164. (New York: The Macmillan Co., 1937.) 12*s*. net.

In "The Science of Musical Sounds", published in 1916, Prof. Dayton C. Miller made available the substance of a series of eight lectures he had given at the Lowell Institute in 1914. The treatment and presentation of his subject were dictated by those circumstances. Though the results of his own investigations rightly received a due share of attention, their description appeared in a setting of "elementary and well known material". Thus the phonodeik, with which the account of those investigations began, was not mentioned until page 78 was reached in a book which, excluding the appendix, contained 270 pages. Moreover, as was natural in a record of lectures in which the audience had a phonodeik before their eyes, the description of the instrument was somewhat brief.

In his new book "Sound Waves, their Shape and Speed", Prof. Miller has produced a story of his investigations which is the complement of his earlier work. Its pages give a straightforward description of his objectives, the methods of attack, the experimental difficulties to be overcome, the means adopted to that end, and a brief outline of the results. The word "story" is used advisedly; for it is this simplification of aim which lends to the book its very real interest. Prof. Miller is not describing a new field of knowledge; Georg S. Ohm and Hermann von Helmholtz had made its general characteristics known more than seventy-five years ago. He is giving a narrative of many years work which has filled in, by the most careful experiment, the details of a large part of the country traversed. That is why few instructed readers who begin the book will be able to lay it aside until they have reached the last page.

As its title implies, the book falls into two parts, dealing in turn with the shape of sound waves and with their speed. The first part sets out much that is of direct interest to musical men of science, particularly in these days when electronic organs are making us acquainted with the synthesis of musical sounds. The six plates have been selected from the musician's point of view. Once the reader has realized, as he cannot fail to do from the description of the technique employed, that the photograph is that of a transverse vibration depicting, as it were diagrammatically, a longitudinal vibration of the most minute character in the air, the curves selected tell their own story. They are all capable of interpretation by the eye, and they cover in a representative manner results of a wide range of interest. Little knowledge of physics other than that which can be picked up by a careful reader is required for their interpretation.

The author gives a much fuller description of the phonodeik than appeared in his earlier book; and this will be useful to anyone interested in the details of his apparatus. In Prof. Miller's own words: "For the investigation of the tone quality of musical instruments, a permanent graphical record of the wave form of the sound seemed necessary; none of the methods for recording sound was sufficiently sensitive and free from influences producing distortion of the wave form." Dimensions and diagrams are given for the constructional details, but it may perhaps be suggested that, in a future edition, a couple of pages at the end of the book might record, for convenience of future reference, actual working drawings for the complete instrument in its final form.

A chapter is devoted to electric-spark photography of sound waves. While it contains little that is novel, it is useful for the excellent photographs it shows. Prof. Miller assumes in his readers a knowledge of the refractive effects, on light, of local variations in the density of air. Perhaps had he begun with a few sentences explaining this to help those who are not physicists, and even a preliminary diagram to show, as in modern textbooks on sound, the wave from the nose of a bullet as the envelope of a series of circles with their centres in its wake, the non-expert would have been encouraged to pursue Part 2, the general outline of which, so clearly described, should have interest for him, despite its technicalities and mathematical equations (which he can skip).

Part 2 deals with a number of experiments on the pressures from gun-fire and on the velocity of sound, which were made possible by exceptional opportunities available during, and just after, the Great War, at the Sandy Hook Proving Ground. Perhaps the most interesting section here is that describing the propagation of explosive sounds through air. Starting with Riemann's formula for the velocity of explosive sound, Prof. Miller describes the experimental precautions by which he was able to take account of the variables affecting his results. He found that "Simple approximate calculations led to the surprising and disturbing result that on a line at right angles to the axis [of fire of the gun], the apparent velocity was sometimes less than normal". The observations he then made led to the view "that the virtual source of the sound, and the centre of the developing wave front in its beginnings, are in effect shot out of the gun, with a speed which may be in excess of that of the projectile itself". The value of these observations is enhanced by the descriptions of the apparatus used and the mathematical analysis of the results. The final pages of the book are devoted to various determinations of the velocity of sound, to which Prof. Miller's own work makes a useful contribution.

The volume will find a place, for future reference, on the book-shelves of all who are interested in the several aspects of the subjects of which it treats.

LL. S. L.

Towards a World Encyclopædia

Encyclopædia Britannica—Book of the Year 1938:
being a Survey of the Principal Persons, Events, and Developments in various Spheres of Knowledge and Affairs during the Year 1937. Pp. xviii+742. (London: Encyclopaedia Britannica Co., Ltd., 1938.) 45*s*.

THE "Encyclopædia Britannica", in common with other institutions of world-wide fame, changes its methods to suit the demands of a changing era. Time was, when a batch of supplementary volumes might be added to the old to make a new edition. So the ninth edition of 1875–1889, reinforced by a massive group of supplements, appeared as the tenth edition of 1902, and this, which was destined to endure until 1911, was replaced in that year by an entirely recast edition, the eleventh—an edition still held in high esteem by those who love the detailed and technical scholarship of the older editions. The twelfth and thirteenth editions were made by adding supplementary volumes to this eleventh edition, and the fourteenth edition of 1931 was almost entirely new, giving expression to a policy which departed from that of the older editions in favour of a rather more popular though not necessarily less scholarly outlook.

But the hurrying years of our generation do not permit of seven- or ten-year intervals between successive editions, and the publishers of the "Encyclopædia", recognizing this, have produced what is to be the first of a series of year-books. The volume under review deals with the movements and events of the year 1937, and it may perhaps be regarded as a step towards the realization of the World Encyclopædia of Mr. H. G. Wells. We say this advisedly, for the volume does certainly fulfil some of the objects of that vastly greater scheme. It does not shirk the discussion of contemporary political and social questions of the highest import; it treats them, in general, in an objective and rational fashion; it gives up-to-date and quantitative political and social statistics; and in many instances, though not in so many as one could wish, it provides pointers to fuller sources of information.

In this volume, the first of an annual series, it is legitimate to expect that many of the articles should deal, not only with developments in 1937, but also with the happenings of the last half-dozen years. Indeed, in some articles, one might reasonably look for a brief, but complete in outline, exposition of the topic in hand. This expectation is, on occasion, realized. Thus the article "Communism" over the initials "E. B." is, as one might have expected it to be, a perfect thumb-nail sketch of the subject. The events of the civil war in Spain are outlined from the Spanish elections of February 1936. On the other hand, the story of the Abyssinian tragedy would seem to be completely inadequate, the events of 1937 being summed up in sixteen lines of text, and no attempt being made, under any obvious heading, to give even in bare outline, the course of the events that led up to the surrenders of the early months of 1937.

It is not easy to devise a fair test for the usefulness of a volume which covers such an immense range of topics, which deals with such vast masses of factual detail. It would be easy (and completely misleading) to put on record occasional instances where the information desired was not forthcoming. The most trustworthy test is to use the volume constantly over a period of some weeks and to note how frequently one is let down. This method has been tried with surprisingly good results. On matters of general interest such as the variation in income tax during the post War period, the criminal statistics of the year 1937, the acreage under root crops, the statistics of rearmament, the Budget, broadcasting, progress in art, music and philosophy, in international trade and international law, detailed and clear information was at once forthcoming. This is also true of more obscure and detailed matters. Thus, to chronicle one example from a score or more of such samplings, information was sought concerning the membership of the communist parties in England and in France. The numbers were listed and easily run down (c. 10,000 and 280,000 respectively). Again, a remarkable change, of recent months, has occurred in the attitude of this party to the policy of a 'United Front', and the year-book, consulted on the matter, points to the reason for this change in a manifesto emanating from the Comintern (the Third, or Communist International) in which the masses in democratic and fascist countries are urged "to work for the establishment of a United Front of anti-fascist forces"! This is but one sample of the minute detail to which the articles condescend, and it speaks volumes for the high standard of the writing and the skill of the editing that so much detail may be filled in without blurring the larger outlines.

The scientific and educational articles do not call for detailed treatment. They are, in the main, written in simple language. No important recent developments are omitted, and advances in the applications of science are fully recorded and explained. Atomic physics; the latest discoveries in biochemistry and in cancer research; developments in power supply: improvements in public and private illumination and its measurement; the design of the latest giant telescope; it would be easy to draw up a list of articles dealing with advances in science, pure and applied, which should exceed this review in length, and would still form but a sample of the part of the volume devoted to matters of scientific interest.

It is an almost impossible task to sum up, in a few phrases which shall not be misleading, the contribution made to the welfare of our society by a massive year-book such as this. Its articles are full, critical and written in clear and non-technical language; they miss little of importance and chronicle many obscure and trivial events—trivial, that is, purely by comparison with some of the happenings of world importance which receive full consideration. War clouds may be gathering; the structure of civilized society may show ominous cracks and fissures; but these are no reasons why we should not interest ourselves in the latest developments in ballet music, the doings of the National Baseball Association, or the whereabouts of Inaccessible Island. Political events are treated in a liberal and objective spirit, though here and there, *rari nantes in gurgite vasto*, articles may be found written in such a spirit of caution as to result in a presentation of meagre, though accurate, detail; the index is a work of art which immensely reduces the labour of search; the production leaves nothing to be desired.

The book may fairly be classed among the indispensables, and one can heartily wish to it and to its successors a complete and unqualified success. Allan Ferguson.

Vergleichende Morphologie der höheren Pflanzen

Von Prof. Dr. Wilhelm Troll. Band 1: Vegetationsorgane. Teil 1, Lieferung 2. Pp. 173–508. (Berlin: Gebrüder Borntraeger, 1937.) 27 gold marks.

ON the first page of this second "Lieferung" of Part I of the first volume, in continuation of the introduction to the main heading, "The Construction of the Shoot and Shoot-systems", the author discusses the 'phyton-theory' of Schultz, Gaudichaud and Celakovsky, but rejects it as not taking account of the structure prevailing at the stem-apex.

Section I of the main thesis on shoot-construction deals with nodes and internodes. Section II treats of the shoot-axis and leaf. Genuine cases of *terminal* foliar organs exist, but they are regarded as derivative. A chapter is devoted to the cortication and alation of the stem by leaf-bases. Leafless shoots form the topic of another chapter, and the rhizophore of *Selaginella* is described and its morphological nature discussed. The author concludes that a comparative and experimental study of the problem shows that the rhizophore is decidedly a modified *stem*. The leafless shoots of Psilotales are described.

In Section III many pages are devoted to the "Phenomena of Lateral Symmetry in the Structure and Leaf-formation of Shoots". 'Flattened shoots' are described in detail. The phylloclades of *Asparagus*, *Ruscus*, etc., are regarded as of shoot nature.

The final section of this "Lieferung" is concerned with the large subject of branching. That of the Pteridophytes and Lycopsidæ is discussed. Considerable space is devoted to the Lepidophytes from the Coal-period. In particular, the *Stigmaria*-problem is fully dealt with. After a special comparison of *Stigmaria* with the mature and seedling structures of *Selaginella spinulosa* and its rhizophores, the author concludes that *Stigmaria* and the rhizophores of *Selaginella* may be regarded, not as a mere "parallel modification" as Scott stated, but as strictly homologous structures.

As in the first "Lieferung", so in this one, the subject-matter is illustrated throughout by very numerous and excellent figures and photographs.

W. C. W.

The Metabolism of the Frog's Heart

By A. J. Clark, M. G. Eggleton, P. Eggleton, R. Gaddie, C. P. Stewart. (Edinburgh Medical Monographs.) Pp. xii+308. (Edinburgh and London: Oliver and Boyd, 1938.) 15*s*. net.

THIS useful monograph contains a full and critical summary of recent work on the chemical processes in the frog's heart and their relation to muscular activity. So much of our knowledge of muscle physiology is based upon those peculiar and highly specialized organs, the muscles of the hind legs of the frog, that information from other sources is needed as a corrective to one-sided views.

On the whole, heart muscle seems to be a more generalized type of tissue than skeletal. As the authors point out, the frog's heart (and perhaps any heart) is not well adapted to correlating energy exchanges, expressed as heat, tension or work, with chemical processes. For this purpose a muscle with straight parallel fibres capable of developing high tensions is necessary. To compensate for these defects, the frog's heart is well suited to measuring the chemical processes themselves, though on account of its small size a very refined technique is needed. The development of this technique has been almost entirely the work of Prof. A. J. Clark and his colleagues at Edinburgh during the past ten years. They are also responsible for most of the results.

The subjects dealt with are as follow: the structure and chemical composition of the heart; oxygen usage and its relation to carbohydrate and non-carbohydrate metabolism; anærobic processes; phosphorus metabolism; the effects of asphyxia and certain depressants on the heart's activity. There follows a discussion of the way the heart's metabolism varies with changes in the electrical and mechanical responses, and of the light these processes throw on the fundamental nature of muscular activity. The last chapter gives a useful comparison of the frog's heart with other types of muscle. There is an appendix on methods.

Through the Great Arid Filter (Man's Drift to Europe)

By A. J. McInerny. Pp. 46. (Otley, Yorks: The Author, c/o Printerdom, 1938.) 2*s*.

MR. McINERNY here elaborates further and in some considerable detail his theory of the part played by the desert in the development of the more advanced races. It is a special adaptation of the more general theory of the influence of geographical environment in moulding man and his culture; but whereas it is most generally held that arable land is an essential condition of progress, the initial stages of cultivation being regarded as the first step towards the higher forms of civilization, the author on the contrary holds to 'thermal aridity' as the efficient cause. The stimulating effect of the solar energy and wide range of variation in temperature of the desert, it is maintained, has transformed non-progressive jungle man into the progressive white races of Europe. On this view, the long-headed races are a product of the desert belt extending from Africa to India, of which the Sahara is the most important section, and the broad- or round-heads emerge from the area of the Caspian. The 'Brown Race', cutting across this desert belt, represents an intermediate stage in the development. In the Far East the Chinese are regarded as the equivalent of the Egyptians, their further development having been arrested for reasons which are stated, while the Japanese represent the Europeans, the efficient cause here being the Gobi Desert.

Mr. McInerny has applied his theory to racial distributions, past and present, with no little ingenuity, and makes it something more than plausible; but until the mental processes underlying progress are more fully understood, as well as the effect of the reactions to 'thermal aridity', it cannot be accepted hastily as proved. In the cultural context, the hypothesis seems to postulate a stimulus which at times is rather remote.

A Short History of Naval and Marine Engineering

By Eng.-Capt. Edgar C. Smith. Pp. xix + 376 + 16 plates. (Cambridge: At the University Press, 1938.) 18*s.* net.

AS the editor of *Engineering* points out in his foreword, most of the material in this work has appeared in the pages of that journal, but its re-issue in book form is more than justified. The author, who is now president of the Newcomen Society, has traced the development of marine engineering from the early reciprocating engine to the turbine and diesel, and from the rectangular flue boiler working at less than 5 lb./in.^{2} to the forced-circulation boiler of to-day. So much of the corresponding development in the field of naval architecture as is required to make a complete picture is also described.

While not in any way a text-book in the conventional sense, a perusal of this book should be as inspiring to the student as it should be attractive to the non-technical reader, to whom more especially the accounts of early voyages of steam vessels will appeal. As a work of reference, it will have lasting value; the index is excellent, and an extensive bibliography is scattered through the text.

In a chapter on the turbine, an intensely interesting light is thrown on the genius of Watt. The author tells us that in a letter full of calculations to Boulton in 1784, after hearing of the re-invention by Kempelen of what was in effect Hero's reaction turbine, Watt wrote with uncanny vision: "So that you see the whole success of the machine depends on the possibility of prodigous velocities . . . in short without god makes it possible for things to move 1000 feet pr″ [i.e., per second] it can not do much harm".

A plea must be made to the author to apply in the next edition the correct epithet to ship-model testing tanks. That of Froude the elder may well have been experimental, but to-day, in an experiment tank, it is only the models which are experimental.

G. V. B.

Elektrotechnische Berichte

unter Mitwirkung des Verbandes Deutscher Elektrotechniker e.V., herausgegeben von Franz Moeller VDE, Berlin. Band 4, Heft 6, 15 Januar, 1938. 6 Bde. yearly. (Berlin: J. Springer.) 48 gold marks each.

THE advent of a major abstracting journal is an event of considerable importance in the scientific world. The subject of this one is electrical engineering. Existing periodicals devoted to abstracting, or indexing, electrotechnical literature are thirteen in number. If we except the *Deutches Rundfunkschriftum* and the *Wireless Engineer*, which include a number of articles of less importance, hitherto no journal has included so many abstracts on electrical engineering as *Science Abstracts* B, and this contains only some three thousand five hundred in a year.

The new journal appears in fortnightly parts, forming six complete volumes annually, and comprising altogether a total of seven thousand abstracts, of which from four thousand to four thousand five hundred are taken from purely electrotechnical periodicals, while the remainder come from journals dealing with general science or cognate subjects, or represent notices of books. The length of the abstracts varies considerably, apparently being adjusted according to the values at which the articles are appraised.

The titles of the articles are quoted, as they should be, in the language of the original, and are also translated into German. The fact that the abstracts are in German is a drawback to English readers. But this difficulty is overcome to a large extent by classifying each abstract minutely by means of the decimal classification, several numbers being added to an abstract if the subject requires. This enables the abstracts of papers on any particular subject to be picked out with the greatest of ease, irrespective of language.

In spite of its high price, this new periodical is likely to become a standard abstracting journal in its subject.

Solvents

By Dr. Thos. H. Durrans. (Monographs on Applied Chemistry, under the Editorship of Dr. E. Howard Tripp, vol. 4.) Fourth Revised and Enlarged Edition. Pp. xvii + 238. (London: Chapman and Hall, Ltd., 1938.) 15*s.* net.

THERE is a plethora of books to-day dealing with one aspect or another of the use of organic solvents in industrial operations. Almost the earliest of these was that of Dr. Durrans; its utility is made clear by the fact that a fourth edition is now required. The preface speaks of a complete revision and amplification and an attempt to make it of use to a somewhat wider industrial field.

In particular, progress has been made in the field of plasticizing solvents. The appendix giving the probable composition corresponding to the numerous trade names for solvents has been enlarged, also the useful table indicating the solubility of sundry resins and varnishes in the solvents.

The book retains its former general character and will be as heretofore indispensable to anyone who has to do with solvents: it is most thorough in every detail.

Die Fermente und ihre Wirkungen

Von Prof. Dr. Carl Oppenheimer. Supplement, Lief. 7 (Band 2, Specieller Teil, Haupt-Teil 16, 17). Pp. 943–1102. 10 fl. Supplement, Lief. 8 (Band 2, Specieller Teil, Haupt-Teil 17). Pp. 1103–1262. 10 fl. (Den Haag: Dr. W. Junk, 1937.)

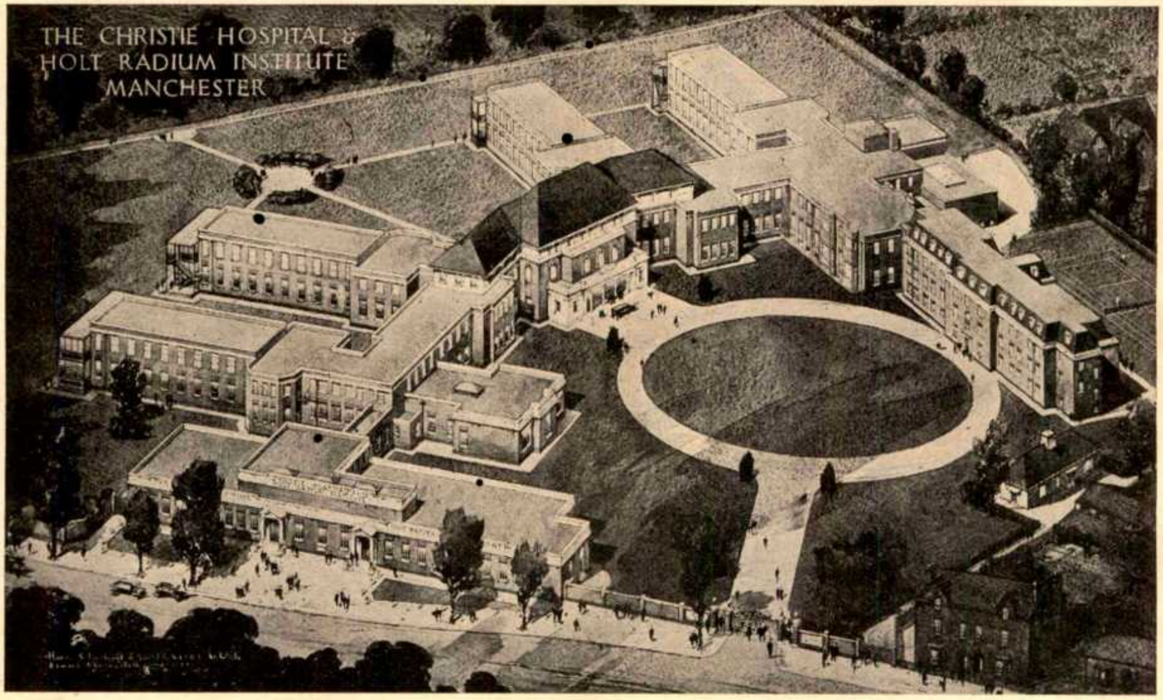
THIS supplement progresses towards its completion which, at the time of writing Part 8, is put down as requiring another six months. The two parts now received deal with thrombase, the fibrin ferment of the blood, and begin the fourth main section entitled "Desmolases". The theories of the oxidation-reduction chain of reactions and the well-known catalysts, including cellular fermentation, are described.

As these matters are in the forefront of interest at the present time, workers will appreciate having the literature summary brought up to date. The treatment follows familiar lines.

The Christie Hospital and Holt Radium Institute, Manchester

SITUATED in the outskirts of Manchester, the Christie Hospital and Holt Radium Institute, which was opened in 1933, presents certain features interesting not only from the medical aspect, but also from the point of view of organization of radio-therapy for malignant disease.

The present institution (Fig. 1.) is the result of the fusion of two much older hospitals; it is one of the largest units of its kind in Europe, and is only exceeded in size by a few American institutions of similar type. Although the main purpose of the unit is the treatment of patients suffering from malignant disease, much experimental work is done concomitantly to advance the scientific practice of radio-therapy, and to study the action of radiation on living tissue.



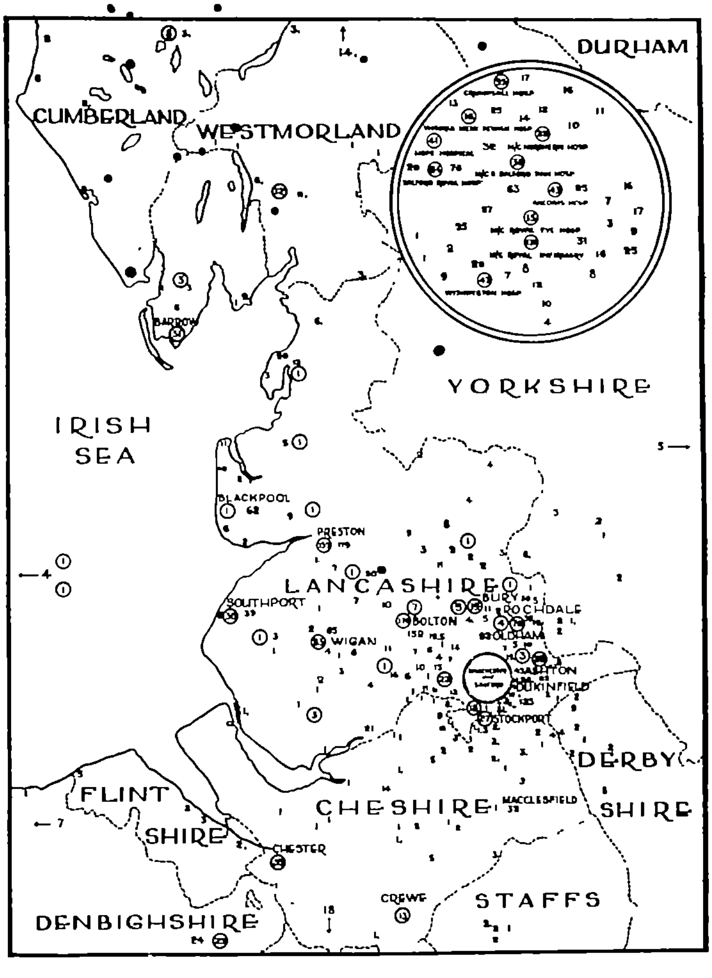
Little need be said about the history of the Institute. The old Manchester Radium Institute founded in 1915 within the confines of the Manchester Royal Infirmary took independent existence in 1921, owing to the generosity and foresight of Sir Edward Holt, at one time lord mayor and a freeman of Manchester. From the beginning, this Institute, under the guidance of the first director, Dr. A. H. Burrows, maintained the principle that radiation therapy should be centralized as an independent specialty. In consequence, Manchester had a long start over many other centres where organization was at first more haphazard. The Christie Cancer Hospital had a longer history. It developed gradually from a cancer home for incurables to an active unit concerned with the surgical treatment of malignant diseases. It then became apparent that expansion was essential, and in 1933, under the chairmanship of F. P. Nathan, deputy-lieutenant of the County of Lancashire, the scope of the work of both units was vastly increased by fusion and removal to the present spacious buildings.

More than six grams of radium are held at present; part of this is owned, and part is loaned from the National Radium Commission. The bulk of the radium is in the form of needles and tubes, with in addition just over one gram in solution for the preparation of radon. With this amount of radium in use, extensive protective devices for the health of workers have had to be developed. From the time the radium leaves the safe, which has protecting walls of 6 in. of lead, until the moment of insertion into the patient, the radium needles remain encased in lead, although in the interval they have been threaded, prepared, sterilized and transported from room to room.

Speaking generally, present-day radium methods consist either of implantation of radium contained in hollow platinum needles into and around malignant growths, or of the application of radium, suitably mounted, superficially to such growths. The former method, implantation technique, is analogous to surgical procedures and requires asepsis and anaesthetics. On the other hand, for radium used superficially, a special laboratory has been developed which combines to some extent the features of a dental workshop with those of a sculptor's studio. Here plaster casts of the tumour-bearing area are made and appliances modelled on these to carry the radium and to fit each patient exactly.

The X-ray Department consists at the moment of a suite of four rooms, each containing an X-ray tube energized at 250 kilovolts. These plants were designed and built by the Research Department of Metropolitan-Vickers Electrical Co., Ltd., and constituted, when first designed, a new departure in the application to medical work of continuously evacuated X-ray tubes and rectifying valves. At the present time, there is being installed a 500 kilovolt unit of similar design. The units are operated with the anti-cathode at ground potential; two advantages accrue from this. First there is the ability to use direct water-cooling of the target from the mains, and second there is the advantage that the high tension is completely removed from the treatment room. Rotation of the head of the tube carrying the target (anti-cathode) is achieved through a gear-driven joint between optically flat steel surfaces. For actual treatment, the emergent beam is defined by applicators which also rotate round the tube, interlocked with the rotation of the target.

The linkage between power units and tubes is of some interest. There are in all four 250 kv. tubes, and two 250 kv. generators. The design is such that each generator can be connected to any or all of the tubes, through one or other of a pair of high-tension leads. To achieve this, each tube has a high-tension change-over switch through which it can be linked to either generator or to earth. The main high-tension leads occupy a special overhead duct behind the treatment rooms. Normal running is usually two tubes to each generator, but there are no fewer than seventy different combinations available for various contingencies. The installation was designed therefore in such a way that any one plant or any one tube could be isolated and repaired in the event of breakdown with the absolute minimum of interference with the general running of the Department.



Areas for which radium therapy service is provided. Figures indicate number of patients referred from each town in 1937. Hospitals receiving radium service, O. Inset map: details of the Manchester and Salford area.

The radiological staff consists of a group of whole-time therapists, and two physicists. The medical and surgical work is dependent on an honorary visiting staff. There are also various auxiliary services. The radiological work is divided amongst the team in such a way that each therapist, in addition to general work, takes over a special small field in which he can become expert and in which he can develop new techniques.

During the last five years, this team has made a number of useful contributions to the science of radio-therapy, particularly in relation to the development of accurate systems of dosage.

To the physically minded, it may seem almost incredible that radium therapy should have been practised until recently on no sound quantitative basis; yet such was the case. Radium dosage was described in terms of the amount of radium used, and for accurate information was relatively meaningless. It was obviously essential to have a unit which states the amount of radiation absorbed at any point, be it in tumour growth or in skin. Some years ago the Manchester School evolved a clinically practical unit of measurement of gamma radiation, selecting for this the roentgen, the internationally accepted unit of X-radiation. This choice was made in order to bring these two essentially similar therapeutic agents to comparable terms. The suitability of the roentgen as a unit of gamma ray therapy was recognized at the recent International Congress of Radiology.

In X-ray therapy also, treatment methods have been open to severe criticism, in that they consisted of a mass of empirical techniques depending on a variety of variable factors, such as so-called 'air dosage', skin tolerance doses, and so forth. The Manchester School has contributed to the clarification of the situation by the development of methods of treatment in terms of accurately measured tumour dosage.

There are three fields in which this knowledge of dosage has proved of immense value. First, information can now be obtained on the tolerance of normal tissue, especially skin, to the effects of radiation, and the importance of the 'time factor' in that respect can be studied. Next, it is at last becoming possible to group tumour growths relatively accurately in accordance with their particular radiosensitivity. Lastly, the value of accurate measurement in the experimental work of the new Research Laboratories of the Institute is inestimable. Research on the biological effects of radiation covers an immense field, but as C. M. Scott has pointed out, the value of much of it has until now been entirely vitiated by the absence of a quantitative outlook.

TABLE 1. NUMBER OF NEW PATIENTS SEEN IN 1936.

Mouth	349
Skin	394
Uterus	200
Breast	298
Pharynx and Larynx	103
Bladder and Rectum	81
Œsophagus and Lung	59
Various Glands	88
Lip	48
Genitalia	51
Other malignancy	160
	1,831
Other conditions—non-malignant	382
	2,213

Cancer is still, after war and the toll of the roads, one of civilized man's most serious menaces, and an inevitable question in considering the work of an institute such as this is as to the results of treatment, and as to whether real advance is being achieved. A very brief review is given, therefore, of the part which radiation plays in the treatment of malignant disease. The scope of radiation therapy can be summarized by an analysis of the types of cases treated at the Institute (Table 1).

Of these numbers, how many are likely to be cured? Table 2 indicates in round figures the achievement of the methods employed in 1932 as assessed to-day (non-malignant group excluded).

TABLE 2. NET FIVE-YEAR SURVIVAL RATE OF ALL CASES TREATED BY RADIATION, INCLUDING ADVANCED CASES.

All types of Malignant Disease (in proportions of Table 1)	40 per cent
Mouth only	30 ,,
Cervix uteri only	30 ,,
Skin only	85 ,,

It will be observed that the figures in Table 2 include the survival rate of all cases treated, whether in the early or advanced stages. A more striking illustration of what can be achieved by radiation therapy is seen in Table 3, from which the very advanced cases have been excluded—a table which at the same time points to the importance of early treatment of malignant disease.

TABLE 3. NET FIVE-YEAR SURVIVAL RATE, EXCLUDING ADVANCED CASES.

All types of Malignant Disease (in proportions of Table 1)	60 per cent
Mouth only	45 ,,
Cervix uteri only	50 ,,
Skin only	90 ,,

Summarizing, it may be said that, while malignant disease remains one of the most serious of diseases, nevertheless something quite definite can be achieved by the methods employed in an institute such as the one under description. The number of patients treated now yearly exceeds 2,000. As estimated from the work of previous years, at least 50 per cent of these will certainly be alive and well three years after, 40 per cent five years after, and unlikely to develop recurrence of their tumour. Unfortunately, many patients at the time they are first seen can only be assisted in a palliative way, the disease having been allowed to progress too far. If we consider the value of treatment in relation only to the earlier lesions, then we find that some 60 per cent of all cases may be expected to be alive and well in five years' time.

As will be seen from Table 1, radio-therapy is at present a method of treatment only applicable to a proportion of all cancer cases, and the number of such cases in even a large population is relatively low. In a population of 100,000 there are probably between 50 and 60 cases of cancer per annum which should be treated by radio-therapy. On this basis, a unit with extensive equipment and a considerable medical staff must serve a very wide area to reach its highest effectiveness. It is estimated that the 2,000 new cases seen annually represents the sifting of cases from a population of approximately 6,000,000. The proportion of cases sent in for treatment from each district tends to vary inversely with the distance from the centre. Thus in the immediate local area (Manchester, Salford and Stockport), practically all cases come for consideration regarding treatment, while in the periphery of the zone served, a smaller fraction is referred unless steps are taken to increase it. This situation is demonstrated by Table 4, which also shows the results of the measures adopted by the Institute to reach patients in the surrounding area.

TABLE 4.

Year	No of patients referred from civic area[*]. (Population 1,039,740)	No referred per 100,000 population.	No. of patients referred from immediately surrounding area[†] (Population 1,663,860)	No. referred per 100,000 population
1931	465	44	362	21
1932	434	41	365	21
1933	474	45	462	27
1934	496	47	736	44
1935	572	55	794	49
Increase over 5 years—25 per cent			Increase over 5 years—133 per cent	

[*] Civic area includes the cities of Manchester and Salford.

[†] Surrounding area is the south-east quarter of Lancashire (excluding Manchester civic area), bounded by the line, Cheshire border, Warrington (exclusive), Preston (inclusive), Yorkshire border.

This improvement in the availability of treatment to patients has been achieved by the development in connexion with the Institute of clinics not only in Manchester in its own hospitals, but also in a large number of voluntary hospitals of towns in the area served (see accompanying map). Treatment clinics are also held, but in a more limited number of such outside hospitals. There the simpler cases are dealt with, while those more complex are brought for treatment to the central unit where the facilities are greater. In the same way the Institute has entered into agreements with City and County Health Authorities by which cases of cancer in their control are seen, and if suitable for radio-therapy are treated.

In conclusion, there are many indications that as national organization for the treatment of cancer evolves, it may be necessary to develop it along lines similar to those now accepted for the treatment of tuberculosis, that is, along modified State service lines. In this case, the unit and the organization described above may prove to have been in some respects a prototype.

Recent Developments in the Geology of the U.S.S.R.

By Prof. N. N. Gornostayev[*]

THE successive Five Year Plans in the Soviet Union have been accompanied by a vigorous development of geological science, and new mineral wealth is being discovered almost daily by the 6,000 geologists who are employed in prospecting over the whole vast area of the U.S.S.R. Soviet deposits of oil, coal, peat, iron, manganese, gold, potash salts and phosphates, are among the largest in the world.

In 1913 the known coal deposits of Russia comprised but 3·2 per cent of the world's resources, as estimated by the Twelfth International Geological Congress. At the Seventeenth Congress held in Moscow last year, the estimated coal resources of the Soviet Union were found to be seven times greater than in 1913, comprising 1,654,361 million tons, or nearly 21 per cent of the world's coal reserves.

In addition to the Donetz Basin, which yielded 87 per cent of the coal mined in Russia in 1913, large coal deposits have been discovered in Kazakhstan, Siberia and the Far East. The coal deposits of European Russia now comprise only 9·1 per cent of the total resources of the U.S.S.R. This more uniform distribution of coal resources has made widespread industrialization much more feasible.

The iron ore deposits of the Soviet Union are now known to be five and a half times greater than was estimated in 1913. The reserves of oil are fourteen times greater than was estimated in 1905. Oil fields have been found along the entire Urals range, and prospecting is in progress on the vast Siberian plains. It is possible that Siberia will be found to contain some of the richest oil deposits in the world. Incidentally, Siberian oil is the oldest known, as it is found in Cambrian formations.

It is now established that about 83 per cent of the world's known resources of potash are concentrated in the U.S.S.R., and these resources are being steadily augmented by new discoveries. More than 73 per cent of the world's manganese ore reserves are contained within the Soviet Union. The huge deposits of apatite found in the Kola Peninsula have doubled the world's resources of phosphates.

---

[*] Revised and abridged by Dr. G. W. Tyrrell from an article entitled "Soviet Geology" received from the Soviet Union Year Book Press Service.

The U.S.S.R. holds second world place in respect of gold output. The gold industry, which formerly employed the most primitive methods, has now been greatly modernized. Large nuggets are often obtained, as, for example, one of 32 kgm. which was found in the Miass (Urals) gold field.

The desolate region of Kazakhstan, the roving ground of nomadic tribes, is now the main Soviet source of supply of non-ferrous metals, especially copper, zinc and lead, and has far outstripped the Urals, the former source of these metals. Until recently the U.S.S.R. was thought to be lacking in boron, but huge deposits of boracic salts have been found in the region around Lake Inder in north-west Kazakhstan.

The geological structure of the U.S.S.R. is exceedingly varied. On its territory are huge mountain folds which have risen on the sites of former sea depressions filled with soft clays, sands and limestones (for example, the Caucasus). There are mountains which are fragments of ancient rocks split into uneven blocks which have moved upward or downward (for example, the Tian-Shan, Altai, etc.). There are deep depressions such as Lake Baikal (the largest freshwater lake in the world, more than 1520 m. deep), and the Black and Caspian Seas, formed in geologically recent times.

The wide plains of West Siberia are now known to cover the greater part of the former range of the Urals. The Urals of to-day represent merely the western margin of this great Hercynian range and, moreover, were elevated in comparatively recent geological times.

Formerly, the Crimean mountain range was as extensive as the Caucasian, but, broken by enormous faults, it sank, and now lies beneath the floor of the Black Sea at a depth of more than 2000 m. The Crimean mountains of to-day are merely a remnant of the northern part of the ancient range.

Some Western geologists have maintained that oceanic depressions have always existed, and that the Pacific Ocean constitutes the 'scar' caused by the parting of the moon from the earth. Recent work by Soviet geologists has shown, however, that the northern part of the Pacific, until comparatively recent times, was a vast continent with mountain chains, hills, plains and volcanoes, stretching between Siberia and North America.

The variety and complexity of geological structures in the U.S.S.R. explain the variety of igneous rocks within its territories. Practically all known varieties of igneous rocks have been found. The largest developments of nepheline-rich igneous rocks in the world, with many rare and rare-earth minerals, and enormous deposits of apatite, have long been known to occur within the Kola Peninsula. Entire mountains of sodic sanidinites, hitherto known only in the form of separate lumps in volcanic ejecta, have been found in Kazakhstan.

Study of the mineral springs of the U.S.S.R. has made it possible considerably to extend the health resorts, not only in the world-famed Caucasian region, which has been greatly enlarged, but also in many other parts of the U.S.S.R., including the Trans-Baikal, Yakutia and the Far East. In the vicinity of Moscow itself mineral waters containing bromine, radium and other valuable therapeutic substances have been found. Geochemistry is flourishing, and discoveries of many valuable minerals are largely the result of geochemical prognoses, which are being made with increasing accuracy and confidence.

The study of marl, alluvium, gravels, sands, clays, etc, is making rapid headway, particularly in connexion with the building of large structures and hydro-technical projects. Data on engineering geology and hydro-geology obtained during the construction of the Palace of Soviets, the Moscow Metro, the White Sea–Baltic Canal, the Moscow–Volga Canal, and other projects, have made it possible to plan more confidently large-scale undertakings such as the Volga Dam and the irrigation of the arid steppes of the Trans-Volga region.

The development of life on the earth began with the appearance of primitive plant life and later of animal life. Until recently, geologists have traced the evolution of life more or less systematically from the Cambrian Period. Of Pre-Cambrian formations it was possible to judge only from accidental and isolated discoveries of fossils. But in Siberia fossil remains of Cambrian and Pre-Cambrian age have recently been found in great abundance, and the study of these remains is one of the most fascinating problems of Soviet palæontology. It is possible that ancient Asia may prove to be the cradle of life on the earth, as it was of the higher forms of animal life, mammals, and even of man.

The remains of mammoths have been found in many places, but only in the north of Siberia are complete well-preserved carcasses of these animals, and of their contemporaries, the long-haired rhinoceroses, found in the natural cold storage of frozen swamps. A special expedition has been organized to study these remains in their natural habitat. Remains of the mastodon, an even more ancient member of the elephant family, have been unearthed in the Kuban in North Caucasus. The tusks of this species were spoon-shaped for the purpose of scooping food from silt and muddy water.

The study of fossil animal and plant life in the U.S.S.R. promises to add much that is new to research on the evolution of organisms under various external conditions.

Obituary Notices

Dr. Géza de Horváth

In these days of narrow specialization it is refreshing to look back on a generation of workers who, by their extensive biological knowledge and literary erudition, were able to deal satisfactorily with the multitude of new forms of life which improvement in transport and the rapid exploitation of the world during the latter half of the last century, were bringing to the European museums.

With the death of Dr. Géza de Horváth at Budapest on September 8, 1937, in his ninetieth year, entomology has lost one of the last of such men. When Horváth was a young man, Prof. Carl Stål, working in the Swedish State Museum at Stockholm, was busy founding the modern classification of the Hemiptera, and it was Horváth and his famous Finnish contemporaries Prof. O. M. Reuter and Dr. E. E. Bergroth, more than any others, who were destined to elaborate this system and build up from it our present knowledge of the systematics of the order.

Horváth was born on November 23, 1847, at Csécs in Northern Hungary. He was educated at the Kassa Gymnasium, where he was a pupil of the celebrated Prof. Jeitteles, and from there went up to the University of Vienna to study medicine. After graduating, he at first worked as an assistant in the Hungarian National Museum, but after about eighteen months he left the Museum to take up a medical practice in the provinces.

In 1880 Horváth was called upon to organize a *Phylloxera* experiment station at Budapest and acted for some time as its director. With the solving of the *Phylloxera* problem throughout Europe, the work of this station was directed towards the control of other injurious insects, and in 1890 it was renamed the Institute of Experimental Entomology. With the help of Jablonowski, such pests as the Moroccan locust, the nun moth, the hessian fly, the frit-fly, the grain sawfly, the grain aphis, clover weevils and the sugar-beet beetle were satisfactorily investigated.

Horváth returned to the National Museum in 1895 and worked as head of the Department of Zoology. Here as a specialist on the Hemiptera, he acquired a world-wide reputation. His systematic papers alone run into several hundreds. He made various scientific expeditions abroad and was a member of the permanent committee of the International Congress of Zoology, and of the International Committee of Zoological Nomenclature. In this capacity he visited the United States in 1907. Horváth was elected a member of the Hungarian Academy and was an honorary member of several foreign scientific societies. In 1927 he was elected president of the tenth International Zoological Congress held at Budapest. He retired from the directorship of the Museum in 1921, but continued to work on the Hemiptera until his death. W. E. CHINA.

Sir Edward Denham, G.C.M.G., K.B.E.

We regret to record the death of Sir Edward Denham, distinguished Colonial administrator and captain-general of Jamaica, which took place on June 2 at the age of sixty-one years.

Edward Brandis Denham was born in 1876, the son of the late Mr. Charles Denham of Sydney. He was educated at Malvern and Merton College, Oxford, and was appointed to a cadetship in Ceylon in 1889 after competitive examination. He had risen in the Colonial service to the rank of principal colonial secretary of Ceylon and colonial secretary of Mauritius, when in 1923 he was appointed Colonial Secretary of Kenya at a time when the present issue of the famous White Paper, laying down the principle of the paramountcy of native interests, was bringing about important changes in the attitude of the administration in dealing with various native questions. The communal system of representation, giving separate representation to Europeans, Indians, Arabs and natives was then being introduced, and in 1924 a measure of self-government was granted to the native tribal councils. These changes threw a heavy burden on Denham's shoulders, which was still further increased when, in 1925, the death of the governor, Sir Robert Coryndon, required him to take up the duties of acting governor, an office which he held until the arival of Sir Edward Grigg as Coryndon's successor in October 1925.

While acting governor, Denham made a tour of the Nyanza and Kikuyu provinces and the Kitui district, the most thickly populated parts of the Colony, with the view of studying the changing mentality of the native in contact with Europeans and their civilization. The results of his observation were embodied in an original and extremely valuable report, which was published as a Blue Book. Especially noteworthy were his remarks on the working of the recently established native councils.

In 1928 Denham was promoted to be governor of Gambia, and in 1930 he was transferred to British Guiana, where he did much valuable work in the development of the resources of the Colony. His appointment as captain-general of Jamaica was made in 1934. His successful efforts in social and economic reform, and the part he played in the recent troubled conditions make his premature death an irreparable loss to the island and to the Empire.

We regret to announce the following deaths:

Dr. Ch. E. Guillaume, formerly director of the Bureau International des Poids et Mesures, aged seventy-seven years.

Prof. Rudolf Vondráček, professor of fuel technology and metallurgy in the Brno Technical College, on June 12, aged fifty-seven years.

News and Views

Prof. Georges Urbain

On June 10, a meeting was held in Paris to mark the fortieth anniversary of the first scientific publication of Prof. Georges Urbain, the distinguished French chemist, member of the Institut de France and director of the Institute of Chemistry in Paris. A committee under the chairmanship of Prof. Jean Perrin organized a meeting at the Maison de la Chimie, where Prof. Urbain was heartily greeted by his colleagues, pupils and friends. Prof. Urbain's name is best known in connexion with his work on the rare earths and with the elements lutecium and celtium or hafnium; but the wide field of his other achievements in the fields of phosphorescence, spectrochemistry and theory of valency, was indicated in a most interesting address by Prof. Lebeau, an old school-friend of Prof. Urbain. Prof. J. Perrin and Prof. P. Langevin in their speeches pointed out that Prof. Urbain was first initiated into chemistry by his father, a teacher in chemistry, and that he continued his studies at the Ecole de Physique et Chemie, where Pierre Curie was a laboratory assistant, scarcely much older than the young and talented student. Hard work in pure science did not prevent Prof. Urbain from developing his gifts in art, for he is a composer of music and excels in sculpture. Several of his musical compositions for piano and organ, as well as for piano and a quartet of string instruments, were produced before the audience. A portrait of Prof. Urbain was made for the occasion by the sculptor Aronson, but several of Prof. Urbain's colleagues have had the pleasure of having their effigies made by the great man of science himself.

Dr. A. R. Todd

Dr. A. R. Todd, who has been appointed Sir Samuel Hall professor of chemistry and director of the Chemical Laboratories in the University of Manchester (see p. 1153), graduated in 1928 with first-class honours in chemistry in the University of Glasgow, where he won the Black Medal, the Roger Muirhead Prize and the Alexander Donaldson Scholarship. From 1928 until 1931 he was a Carnegie Research Scholar, working first at Glasgow under Prof. T. S. Patterson and later in Frankfort-on-Main under Prof. Borsche. Afterwards, as 1851 Exhibition Student, he worked for three years under Prof. R. Robinson at Oxford. In 1934 he became assistant to Prof. G. Barger in Edinburgh, where he held a Beit Memorial Medical Research Fellowship. In 1936 he was awarded the Meldola Medal, and in the same year he joined the Lister Institute as assistant in the biochemical department. Dr. Todd has published some thirty papers in chemical journals dealing with work on rotatory dispersion and the Walden inversion, the structure of bile acids, anthocyanin pigments, the chemistry of vitamins B_1 and E and other biochemical subjects. He enters on his new appointment at the end of September of this year.

Tercentenary of the Birth of Prof. James Gregory

The University of St. Andrews will commemorate on July 5 the three hundredth anniversary of the birth of James Gregory, professor of mathematics in the University from 1668 until 1674. The actual date of his birth at Drumoak, twelve miles from Aberdeen, appears to have been November 6, 1638, but the mathematical colloquium to be held in St. Andrews in July affords a suitable opportunity for this celebration. An address on Gregory and his work will be delivered in the Upper Library Hall, where his meridian line was traced on the floor, followed by a graduation ceremonial at which honorary degrees will be conferred on distinguished representatives. On the previous day, the Royal Society of Edinburgh is holding a meeting at which papers will be read on the mathematical and astronomical work of the inventor of the Gregorian telescope, who died in that city in October 1675 shortly after his transference to the chair of mathematics in the University of Edinburgh.

Charles Hilton Fagge (1838-1883)

This distinguished London physician was born on June 30, 1838, at Hythe in Kent, where his family had been in practice for two generations, and was the eldest of three brothers who joined the medical profession. He was educated at Guy's Hospital, to which he was appointed assistant physician with charge of the skin department in 1867, six years after qualification, and full physician in 1880 in succession to Dr. Habershon. He was also for many years curator of the museum, for which he compiled a catalogue of the models of the diseases of the skin in 1876. His literary output was considerable. His most notable papers were the articles on "Diseases of the Valves of the Heart" contributed to Russell Reynold's "System of Medicine" and those on "Sporadic Cretinism", "A Line on the Gums Characteristic of Lead Poisoning", and the "Probable Cause of Lead Colic" in the *Medico-Chirurgical Transactions*. To *Guy's Hospital Reports*, of which he was editor for some five years, he contributed a classical paper on "Acute Dilatation of the Stomach" in 1873, in addition to other articles. In 1866–68, in collaboration with J. H. Pye-Smith, he translated and edited for the New Sydenham Society two volumes of Hebra's "Diseases of the Skin", the translation of the remaining five being the work of Mr. Waren Tay. His work on the "Principles and Practice of Medicine", on which he had been engaged for ten years at the time of his death, was completed and edited by Pye-Smith. The cause of his death on November 19, 1883, at the early age of forty-five years was aneurysm of the aorta, the existence of which in his own person he had discovered about eighteen months previously while demonstrating the use of the binaural stethoscope. He nevertheless preferred to die in harness, a decision which met with the approval of Osler, among others.

A New Treatment of Pneumonia

SYNTHETIC compounds possessing specific curative effects in various infections—'chemotherapeutic agents' as they are termed—have long been sought for, though without much success, at least in bacterial infections. Three years ago, 'Prontosil', a sulphonamide compound, proved valuable in the treatment of streptococcal infections, such as puerperal fever. Quite recently, L. E. H. Whitby, investigating experimentally a number of synthetic compounds, found that one of them, 'M. & B. 693', had a marked specific effect upon the pneumococcus, the microbe of human pneumonia, almost complete protection being afforded against Types i, vii and viii pneumococcus infections, and a high degree of protection against Types ii, iii and v (*Lancet*, 1, No. 22, 1210; May 28, 1938). Encouraging clinical results in cases of pneumonia in man were reported by Evans and Gaisford (*Lancet*, 1, No. 23, 1305; June 4, 1938), and Telling and Oliver now give details of another case treated with this agent (*Lancet*, 1, No. 25, 1391; June 18, 1938). The patient, an old lady, was critically ill with pneumonia, pneumococcus Type iii being recovered from the sputum. After four days' treatment with the drug, recovery commenced and was finally complete. The observation was made that, in the course of treatment, the capsule which surrounds the pneumococcus became lost, and other changes in the organism were apparent. 'M. & B. 693', chemically, is 2-(*p*-aminobenzenesulphonamido) pyridine.

Organization of Archæological Research in India

As was pointed out recently in these columns (see NATURE, May 28, p. 965) little advantage has been taken of the facilities for archæological exploration offered some years ago by the Government of India to bodies from outside the country, nor, if Dr. E. Mackay's excavations be excepted, has a serious and systematic attempt been made on any adequate scale to follow up the discovery of the now famous early civilization of the Indus Valley. An indication that a forward policy is now contemplated is afforded by an announcement of the India Office that Sir Leonard Woolley has accepted the invitation of the Government of India to visit the country next winter before proceeding to Syria to resume his excavations in the spring of 1939. The object of the invitation is to secure his advice in regard to a programme of archæological work. Among the matters upon which it is understood that Sir Leonard will be consulted are, first, the areas which are to be regarded as most promising for future excavation; secondly, the best methods and agencies to achieve the speedy and fruitful development of exploration activities, not only under Government auspices but also by non-official bodies, such as universities and learned societies; and last, the best method of training, or selecting, officers for exploration work, including such points as the most suitable age for recruitment. Since the control of the Archæological Survey has passed into Indian hands, much excellent work has been done, more especially in those departments dealing with the growth of Indian civilization at periods with which her countrymen perhaps are more familiar and more competent to speak than 'foreigners'. The archæology of India is a subject for which her native students have shown both enthusiasm and aptitude; but they have had little opportunity to acquire the breadth of outlook which the study of the pre- and protohistory of their own country demands. The determination to seek outside advice and the choice of an adviser are wise steps, from which archæological studies throughout the world may expect to reap considerable benefit.

Peoples of Ancient Syria

EVER since the recognition of Sumerian influence in the Indus valley through discoveries in the excavation of Mohenjodaro and Harappa, archæological investigation has added continuously to the evidence of the remarkable, and it may be said, unexpected degree and geographical extent of the contacts and movements of cultures and peoples even in the early stages of the development of civilized society. Now Mr. Sidney Smith, in a communication to *The Times* of June 16, indicates how a preliminary examination of the tablets from the Palace excavated by Sir Leonard Woolley at Atchana affords evidence of the extremely mixed character of the population of Syria in the fifteenth century B.C. In ancient times, it would appear, the site of Atchana was known as Alalakh. It was the capital of the country, Mukish-khe, mentioned in Hittite and Egyptian records. It was a vassal State of the kingdom of Mitanni, as appears from a tablet recording an attempt to establish citizenship of a Mitannian province, brought before the king of that people about 1450 B.C. by a subject of Niqmepa, ruler of Mukish-khe. The documents which have been found at Atchana, Mr. Smith states, concern the status of certain citizens, and are in the Akkadian language. From the names recorded it is possible to deduce that the population contained a considerable proportion of Babylonians and of Khurrians, an indigenous people in Mitanni, but spread over a considerable area extending from Kirkuk, east of the Tigris, to northern Palestine, and of whose existence no knowledge survived prior to modern excavation. Niqmepa may be a Khurrian name, but his son's name is Babylonian. This, Mr. Smith points out, is merely another phenomenon of a mixed civilization, in which the predominant elements were Babylonian, apart from local law and administration. He goes on to say that the inscribed seal, to which Sir Leonard Woolley referred in his report, is no proof of Hittite conquest. The language of the Hittite hieroglyphs is not Hittite, though it may be Indo-European. The seal is, therefore, merely further proof of the mixed character of the population.

Patents, Designs and Trade Marks

THE fifty-fifth report of the Comptroller-General of Patents, Designs and Trade Marks presents, as usual, a solid mass of information about the volume of business handled during 1937 in the Patent Office (Patents, Designs, and Trade Marks. Fifty-fifth Report of the Comptroller-General of Patents, Designs, and Trade Marks, with Appendices, for the Year 1937. Pp. 25. London: H.M. Stationery Office. 6*d*. net). Applications for patents, which should reflect the inventive activity of the country, went over the 35,000 mark during the year, and the work of the 821 members of the staff resulted in a surplus of close on £300,000. Two pages of the report are devoted to an account of the trend of invention to-day. Synthetic drugs, for example, sulphonamides, have had much attention, and hormones—to borrow a Stock Exchange phrase—are a strong feature. The special needs of bombers and bombs and the general demands of industry have caused the problems of getting and successfully using the extra-light metals magnesium and aluminium to be continuously tackled.

IN the patent field, application activity often diminishes in quarters where the main problems have been solved and the stage of bulk production has been reached. For this reason, applications for patent protection for mercury arc rectifiers have fallen off, but television applications are more than maintained. The report itself should be read to get a comprehensive survey, but one of the most curious instances of the application of science to the peculiar needs of modern life should be noted; inventors have been busy with various forms of chance-apparatus for use by those who fill up football-pool coupons. Patents make strange bed fellows and air raids precautions succeed pool coupons in the report. The Comptroller has clearly had a busy time with legislation, as 1937 saw both a Patents and a Trade Marks Bill introduced into Parliament. Of these, the Trade Marks Bill has now gone through all its stages and received Royal assent.

Expenditure on Public Social Services

A RETURN showing the total expenditure under certain Acts of Parliament in the financial years 1900, 1910, 1920, 1930, 1935 and 1936 on public social services has recently been issued, covering expenditure from local rates, Parliamentary votes and other receipts, not being loans or receipts for capital purposes. The first part of the return shows that the total expenditure on these services in England and Wales has increased from £31·7 millions in 1900 and £54·95 millions in 1910 to £412·8 millions in 1930 and £440·5 millions in 1935. For 1936, the expenditure is estimated at 326 millions. The largest single item of expenditure is that under the Education Acts, which has increased from 16·9 millions in 1910 to 97 millions in 1935. Expenditure under the General Scheme of Unemployment Benefit in 1935 was 45·7 millions and Unemployment Allowances and Benefits 38·9 millions. Expenditure under the Old Age Pensions Acts has risen from 6·3 millions in 1910 to 39 millions in 1935, under the National Health Insurance Acts from 26 millions in 1920 to 34 millions in 1935. Under the Housing Acts expenditure has risen from 0·4 millions in 1900 to 42 millions in 1935, while under the Acts relating to the relief of the poor, expenditure has risen from 11·5 millions in 1900 to 44 millions in 1935. Public Health Acts now account for an expenditure of 16 millions as against a little over a million in 1900. Expenditure under the War Pensions Acts and Ministry of Pensions Act has decreased from 90·9 millions in 1920 to 36 millions in 1935. Expenditure in Scotland on the same services shows similar trends, the total having risen from £4·3 millions in 1900 to £50·3 millions in 1935. Particulars of the number of persons benefiting from this expenditure are included.

Training for Responsibility and Control

A REPORT on education, selection and training for positions of responsibility and control, by W. R. Dunlop, 57 Gordon Square, London, W.C.1, gives a summary of published views and methods in Great Britain with reference to executive and administrative positions in industry, commerce, agriculture, the civil services, the army, etc. Attention is directed to the confusion or disagreement as to management terminology in general, as to the main function of the educational system, the value of public school education and of social qualifications for positions of responsibility or control. On the other hand, the general agreement that, so far as management is concerned, the subject of a university degree does not greatly matter, which is emphasized by Mr. Dunlop, should be noted by scientific workers in supporting their claims for equal consideration for admission to administrative posts. Other matters on which there is general agreement are the necessity for avoiding excessive specialization in training; the importance of linking training for management with employment; the value of the "Case" method in specialized training; the unreliability of selection by interview or examination and especially the unsatisfactoriness of committee interviewing.

AMONG many specific recommendations of the report are the recognition of the value of the psychological view in education, selection and training and of the importance of moral principles in management. An adequate article in the "Encyclopædia Britannica" is advocated, and in regard to general education the significance of history and geography is stressed. Views on the transfer of subjects problem require further investigation, and more attention should be paid to the wider aspects of selection, such as systems or policies, as well as to the forecasting of vacancies. Managerial job analysis, attention to the claims of older and not exclusively the younger men, probationary periods, to the theoretical side of training schemes in industry and the development of an administrative section in the libraries of Government departments and business firms are also recommended. In addition to the list of findings and recommendations, the report includes a fairly comprehensive bibliography the value of which unfortunately is considerably diminished by the incompleteness of the bibliographic detail.

The Service of Unified Knowledge

SOME time ago (November 18, 1936) we discussed, under the above heading, Mr. H. G. Wells's "Idea of a World Encyclopædia", a project designed "to hold men's minds together in something like a common interpretation of reality". Six months later (May 29), we published an article discussing Prof. Dobrowolski's scheme for paving the way for such a common interpretation by equipping every university with a "faculty of general knowledge". A full translation of its author's own account of the scheme appeared later in the *Sociological Review* (October 1937), including a description of the organization, subject-matter, time-tables and method of instruction of "Universitas Rediviva", a working model of the proposed faculty of general knowledge in operation in Warsaw. In the meantime, Mr. H. G. Wells has outlined in his address at Nottingham to Section L (Education) of the British Association, his ideas as to the informative content of the kind of liberal education that might be expected to produce minds capable of being held together by his world encyclopædia. The importance of such a "holding together of men's minds" has been clearly seen by the creators of the modern dictatorial regimes. In democracies it is equally important but much more difficult to achieve. Both Wells and Dobrowolski would probably subscribe to A. N. Whitehead's dictum: "There can be no successful democratic society till general education conveys a philosophic outlook" ("Adventures of Ideas". Cambridge: University Press, 1933).

Accessions to the British Museum (Bloomsbury)

AMONG accessions to the collections of the British Museum (Bloomsbury) reported at the June meeting of the Trustees is a remarkably fine spearhead found in the Thames at London, which has been on loan since 1931, and has now been presented to the Museum by the owner, Capt. John Ball. The spearhead, on account of its graceful shape, ranks with the famous Battersea shield and other examples of Celtic art in Britain of the period of high æsthetic qualities. It is of iron with two applied plates of bronze on each side, ornamented with Celtic scroll pattern. It dates from the beginning of the first century A.D. The most important accession to the Ethnographical Department consists of a generous selection of the antiquities from the Bay Islands off British Honduras, which were recently on exhibition in London (see NATURE, May 21, p. 932). These have been given by Lord Moyne, by whom the excavations were carried out. The remainder of the collection has been sent to Cambridge for study and distribution among various institutions. The examples of the Bay Islands culture allotted to the British Museum include a number of ocarinas or pottery whistles of various shapes, including a notable specimen in the form of a jaguar, while a remarkable product of the potter's art is a monkey swinging from a bough. The selection also includes a number of the small carvings in jadeite and soapstone and several of the stone hoes, while a large pottery beaker is especially interesting, as being comparable with one carved in white stone coming from the mainland of Honduras, which was already in the Museum. The Bay Islands culture is thought to date from between A.D. 1000 and 1500.

Recent Advances in Bird-Ringing

BIRD-RINGING in Britain, now organized from the bird room of the British Museum (Natural History), shows an increase not in the actual number of birds marked, but in the number of adult birds 'trapped' and thus marked and released, and a decrease in the number of nestlings marked; the mortality amongst nestlings is naturally high and thus the chances of recovery of ringed nestlings fewer. The statistics for 1937 show that 45,181 birds were ringed in Britain (*British Birds*, April 1938), as against 48,663 the previous year, bringing the grand total of birds marked in the country since the scheme was started in 1907 to 575,914. There was a record total of 'trapped' birds last year of 21,900 compared with 19,235 birds last year, and it includes a number of rarities not marked before, such as the waxwing and little bunting. Skokholm Bird Observatory, South Wales, for example, marked 4,402 birds in 1937, including the valuable total of 1,448 Manx shearwaters, 904 gannets and 603 razorbills. Mr. G. Charteris's list of 3,044 birds marked included 1,396 chaffinches, mostly at a winter roost; Mr. P. Morshead's total of 2,546 birds included 1,272 'trapped' starlings; Mr. A. Maynall's 2,024 birds including 348 nestling nightingales. The Zoological Society of London (through Mr. E. A. Billet) ringed a total of 1,144 birds at Whipsnade last year, these including 333 'trapped' jackdaws. Some of the leading boys' schools again take a prominent place in the ringing returns. Owing to the increased cost of the rings and the organization, there is an appeal for funds in addition to the general charges for the rings used.

Systems of Units

THE February issue of the *Journal of the Franklin Institute* contains a paper by Prof. W. M. Hall, of the Massachusetts Institute of Technology, on the formation of systems of units, which embodies portions of a 1936 copyright publication on the subject. The conditions for a self-consistent system of units are laid down and for translational kinematics length and time taken as fundamental. Translational kinetics then gives mass and rotational angle. Thermodynamics introduces temperature, light visibility and sound audibility. Electrodynamics admits of two possibilities: permittivity or permeability may be taken as fundamental and give the electrostatic or electromagnetic systems respectively. The questions of the sizes of the units to be chosen for convenience and of rationalizing or subrationalizing the units in which the coefficient 4π appears are discussed. Tables are given in which the units of the following systems are compared. The electromagnet with centimetre, gram, second and permeability of vacuum fundamental, the electrostatic with permittivity replacing permeability, and rationalized and subrationalized forms of each, the Gaussian mixed system with some quantities expressed in electromagnetic others in electrostatic units, the rationalized form of this, introduced by Heaviside and Lorentz, the Maxwell quadrant (10^9 cm.), 10^{-11} gram, second and permeability of vacuum, the Bennett and others, centimetre, 10^7 gram, and a unit of permittivity of vacuum $= 1/(8 \cdot 989 \times 10^{11})$, the Giorgi, metre, kilogram, second and 10^7 times the permeability of vacuum. The last three systems all have the ampere, volt and watt as units of current, potential and power respectively.

Trend of Design of Electric Locomotives

The paper on the trend of the design of electric locomotives during the last ten years, read to the Institution of Electrical Engineers by C. E. Fairburn, the electrical engineer to the L.M.S. railway, is a valuable contribution to electric traction. He shows clearly that there is a growing demand for locomotives of greater power and speed. This is due partly to the necessity of improving running schedules with heavier trains and of avoiding the higher cost of multiple operation. Fairly complete data are given of ten electric railways in eight different countries and from twelve manufacturing companies. To analyse them is difficult because the outlook and methods vary not only from country to country but also from railway to railway in the same country. In Austria, Germany, Switzerland and Sweden low-frequency alternating current is employed; in Belgium, Italy and Poland, 3,000 volts direct current; France, Holland, Japan and much of the British Empire, use 1,500 volts direct current. Three-phase systems seem to be making little progress. In Germany, the express locomotive of the German State Railways is of 4,150 horse-power. Recent Swiss locomotives have 8,630 horse-power and the articulated express locomotives of the Pennsylvania Railroad can supply 9,500 horse-power for a short period. General experience with high-power locomotives, in particular on the Pennsylvania Railroad, shows that even larger horse-powers are desirable, especially on lines carrying heavy traffic. It is definitely stated that the advantages of electric braking on long gradients lie more in the reduction of wear in the mechanical parts than in the value of the energy returned to the supply system. With high speeds it is advisable to retain mechanical brakes for emergency operation as this makes higher speeds possible with safety.

Water Heating by Electricity

At a meeting of the Association of Supervising Electrical Engineers held in London on April 12, P. Honey discussed the technical aspects of water heating by electricity. Since two trades were involved, namely, plumbing and wiring, the question of responsibility for satisfactory working has to be considered. The retailer of the appliance has to take upon himself the responsibility of planning the installation and, with the co-operation of a hot-water fitter, make certain that the workmanship is good. The problems of the water authorities are similar, in some respects, to those of supply undertakings. Unlike electric supply they have not the stimulus of competition. As water for domestic purposes is rarely charged for by quantity, the most urgent need is to prevent waste. They have therefore insisted that the fittings and appliances should be in accordance with certain specifications. To eliminate 'peak' demands which would cause serious drop in water pressure, the use of feed cisterns is insisted on by many authorities to ensure a more even demand. The amount of storage water held in this way in the houses of consumers is a considerable fraction of the total stored by the authorities. Regulations, therefore, were issued which restricted the connexion of electric water heaters of the thermal storage type direct to the cold water main. For example, in London, no heater larger than three gallons must be connected in such a manner. Those of larger size must be fed from an adequate storage system. No water authority in Great Britain would permit the connexion of a pressure water heater direct to the cold mains in the way frequently done abroad. The cost of servicing electric water heaters of all kinds is not a serious item. The majority of the few electrical defects which occur are probably due to the thermostat and are not serious.

Education in 1932-1934 in the United States

The United States Office of Education has recently published its "Biennial Survey of Education 1932–1934" (Washington: Government Printing Office. Pp. 1222. Price 1.10 dollars). The effects of the economic depression, which touched its lowest point in 1932, are reflected in many of the statistical tables. The total aggregate income for education from kindergarten upwards in 1933–34 was about 2,604 million dollars, of which huge sum more than five sixths represent income of publicly controlled institutions. Compared with the corresponding figures for 1931–32, there was a decrease of 15·5 per cent, and compared with those for 1929–30 a decrease of 22·6 per cent. It is noteworthy that the decrease was twice as heavy in privately controlled as in publicly controlled institutions from 1932 to 1934, although it had been much lighter in the preceding biennium. Statistics of university enrolments which had risen continuously for many years showed a sharp drop after 1932. It is estimated that the percentage of boys and girls who on completion of their secondary school education entered a university or other institution for further education was in 1933 about 26. This is a high figure compared with the corresponding percentage in Great Britain, but it is low compared with the average percentage (44) of the years 1921–1929 in the United States.

University College, London

Its recently issued annual report shows that this most cosmopolitan of all colleges in Great Britain numbered last year among its 3,284 students no fewer than 910 visitors from 52 countries outside the British Isles. By far the biggest contingent, 228, came from India. From Germany came 73, Scandinavian countries 47, Switzerland 30, France 25, Holland 21; from Australia 30, New Zealand 27, Canada and Newfoundland 45, the United States 43, South Africa 37, Egypt 26, Palestine 28, China 35. For some years past the College reports have directed attention to the increase in the number of post-graduate and research students. Last year these advanced students numbered 616, and it is noteworthy that more than 40 per cent of them were from abroad, including 81 from India, 24 from Canada and Newfoundland, 23 from China, 22 from New Zealand, 18 from Australia, 18 from South Africa, 10 from the United States and 10 from Germany. A list of more than five hundred original papers and other publications from the various departments of the College in 1937 is appended to the report. A coloured plan shows graphically the growth of the College site and buildings since 1827.

Health of School Children

The annual report for 1936 of the chief medical officer of the Board of Education, Sir Arthur MacNalty, entitled "The Health of the School Child" (London: H.M. Stationery Office. 2*s*. 2*d*., postage included) states that, during the year in question, the nutrition of more than 1,700,000 children was assessed with the result that 14·6 per cent were regarded as excellent, 74·2 as normal, 10·5 as slightly subnormal and 0·7 as bad; these figures are substantially the same as those in the report for the previous year. Free school meals provided have increased from 87,000,000 in 1935–36 to more than 100,000,000 in 1936–37. More than half the children who could receive milk either free or at half-price still fail to take it. Medical inspection and eyesight, care of the teeth, physical training and recreation and the national health campaign are some of the other subjects dealt with in this report.

Netherlands Indies

The Colonial Institute of Amsterdam, which maintains a research department and an economic museum as well as an ethnographical department in conjunction with the Netherlands Pacific Institute, has published the first number of a new quarterly entitled *Bulletin of the Colonial Institute of Amsterdam* (18*s*. a year). The aim of the new publication is to give authoritative articles in English on various aspects of the Netherlands Indies. Only a small part of each number will be written in Dutch. Articles of scientific interest in the first number treat of malaria in the Netherlands Indies, social organizations of the peoples of Borneo, Celebes and the Moluccas, and air transport in the Pacific.

Asbestos

A recent publication of the Mineral Resources Department, Imperial Institute, is a monograph on asbestos by Mr. G. E. Howling (second edition. 2*s*.). The volume includes a discussion of occurrence, mining methods, uses, marketing and world production, and ends with a full bibliography.

Universal Esperanto Congress

The thirtieth Universal Esperanto Congress will be held in London on July 30–August 6, under the high patronage of H.R.H. the Duke of Connaught. The total membership of the Congress is expected to be about 1,500, of whom some 1,300, representing twenty-five nationalities, had been enrolled at the beginning of June. The official proceedings will, as usual on these occasions, be carried on in the international language alone, no interpreters being employed either at the general meetings or at the sectional gatherings of specialists. Among the social features of the week will be two performances in Esperanto of "Eliza Comes to Stay" by members of the Neilson-Terry Guild of Dramatic Art, who have been learning the language for the purpose. It has been decided to hold next year's Congress at Bern, Switzerland.

The Night Sky in July

The moon is full on July 12^{d} $15{\cdot}1^{h}$ and new on July 27^{d} $03{\cdot}9^{h}$ U.T. The only bright star to be occulted this month is λ Piscium, the reappearance of which will be visible from Greenwich on July 18 at 2^{h} $22{\cdot}4^{m}$, at position angle 198° from the north point of the moon's image. Lunar conjunctions with the planets occur as follows: with Jupiter on July 16^{d} 7^{h}; with Saturn on July 20^{d} 0^{h}; with Mercury on July 29^{d} 5^{h}; and with Venus on July 30^{d} 9^{h}. On July 26, Mercury is near Regulus, the minimum apparent separation (geocentric) being 0·9°; and on July 31^{d} 7^{h} Mercury is in conjunction with Neptune, the separation being 0·4°. Venus is a bright evening star, setting about 1^{h} 40^{m} after the sun in mid-July. Jupiter and Saturn are both visible during the night, Jupiter, a very bright object, southing about $2\frac{1}{4}^{h}$ in the middle of the month and Saturn three hours later. The interesting phenomena (eclipses, transits, occultations) of the Jovian four inner satellites may be followed with the help of the table and diagram given on p. 613 of the *Nautical Almanac* for 1938 or of the table on p. 170 of *Whitaker's Almanack*. At 22^{h} in mid-July, Vega is nearing the southern meridian and precedes the Milky Way. The bright star Deneb (α Cygni) on the galactic equator marks the apex of the bifurcation of the Milky Way, one branch passing southwards through Serpens and Scorpio; the other through Aquila, Scutum and Sagittarius. Interesting objects for telescopic examination abound in this region, which is also the habitat of the novæ. The 6th magnitude double-star, 61 Cygni, was the first star to have its distance successfully measured one hundred years ago by Bessel, who made his measures with a heliometer. His results gave the star's distance as 640,000 times that of the earth-sun distance; modern measures give 680,000 times this unit.

Announcements

The Right Hon. Neville Chamberlain has been elected a fellow of the Royal Society under Statute 12, which provides for the election of persons who "either have rendered conspicuous service in the cause of science, or are such that their election would be of signal benefit to the Society".

PROF. J. E. LITTLEWOOD, Rouse Ball professor of mathematics in the University of Cambridge, has been awarded the De Morgan Medal for 1938 of the London Mathematical Society. The Medal, which is awarded triennially, will be presented at the next meeting of the Society, on November 17.

THE following grants and scholarships from the Lady Tata Memorial Fund for research in blood diseases, with special reference to leukæmia, have been made for the academic year beginning on October 1, 1938: grants for research expenses or for scientific assistance: Dr. Julius Engelbreth-Holm (Copenhagen), Dr. M. P. J. Guérin (Paris), Prof. Dr. Karl Jármai (Budapest), Prof. James McIntosh (London), Prof. Eugene Opie and Dr. J. Furth (New York), Dr. Georg Weitzmann (Leipzig), Dr. Joachim Wienbeck (Breslau); whole-time scholarships: Dr. Jørgen Bichel (Aarhus, Denmark), Dr. Edoardo Storti (Pavia, Italy); part-time scholarship: Dr. Werner Jacobson (Cambridge).

MR. M. A. BAILEY has been appointed director of the National Institute of Agricultural Botany in succession to the late Mr. W. H. Parker, who died in January last. Mr. Bailey was educated at Dulwich College and Clare College, Cambridge, taking the Natural Science Tripos Part I (first-class honours) and the diploma of agriculture. After war service, during which he held the post of brigade major in the Royal Field Artillery, he was appointed botanist to the Egyptian Government. This was followed by service with the Empire Cotton Growing Corporation and his appointment as director of agricultural research to the Sudan Government, from which he has recently retired.

THE annual inspection of the National Physical Laboratory will be held on June 28.

THE new building for the Radcliffe Telescope at the University of London Observatory, Mill Hill Park, N.W.7, will be opened by the Astronomer Royal on July 1 at 4 p.m.

ON the occasion of the twenty-fifth anniversary of its foundation, the Swiss Rontgen Society has elected the following honorary members: Dr. C. Thurstan Holland of Liverpool, Profs. R. Kienbock of Vienna, Holthusen of Hamburg, Hans Meyer of Bremen, Perussia of Milan, De Quervain of Bern and Regaud of Paris.

PROF. WILHELM KREIS, of Dresden, has been awarded the Goethe Medal for Art and Science.

A NEW Institute of Medical Chemistry has recently been inaugurated by the Faculty of Medicine at Keio, Japan. The building alone will cost 100,000 yen. The new institute will serve not only as a research centre but also as a hospital.

DR. VICTOR E. LEVINE, professor of biological chemistry and nutrition at the Creighton University School of Medicine, has established a laboratory at Point Barrow equipped with all the latest apparatus for carrying on medical and biological research in the Arctic.

THE bronze Heberden Medal is to be awarded annually to a registered medical practitioner for the best work in the British Isles on the investigation of rheumatic diseases. The recipient will be invited to deliver the Heberden Lecture, which should contain a review of the work carried out for the award of the medal. The first award will be made in January 1939. Further information can be obtained from the Hon. Secretary, Dr. Kenneth Stone, 58 Chesterfield Gardens, W.1.

THE Institute of International Education announces that a Woolley scholarship in Paris is offered to a student in psychiatry for the year beginning October 1. The scholarship consists of 600 dollars and a room in the United States House of the Cité Universitaire in Paris, under whose auspices the offer is made. The candidate must be an American citizen. Applications should be made to the Institute of International Education, 2 West Forty-Fifth Street, New York.

A SUM of 66,000 dollars has been made available by the Rockefeller Foundation for the department of hospitals for the support of research on chronic diseases at the hospital now under construction at Welfare Island. The subjects for study include rheumatoid arthritis, the role of nutrition in chronic diseases, the role of cholesterol metabolism in arterio-sclerosis, circulatory and respiratory factors in pulmonary emphysema, bacteriological and immunological factors in acute and chronic glomerulonephritis, and various factors in hypertension.

THE Central Association for Mental Welfare has arranged a course for persons engaged in the training of mental defectives in occupation centres and institutions or mental hospitals and for home teachers to be held in London on July 4–23; also a course for officers of local authorities and local associations for mental welfare engaged in the ascertainment and supervision of defectives during the same period. Further particulars may be obtained from the Educational Secretary, Central Association for Mental Welfare, 24 Buckingham Palace Road, S.W.1.

COURSES on the "Physics of Metals", arranged especially for teachers, will be held in the University of Pittsburgh on July 5–August 12. Lectures will be delivered by Prof. N. F. Mott, Melville Wills professor of theoretical physics in the University of Bristol, who will be in residence for six weeks; Dr. John Bardeen, fellow of Harvard University, recently appointed assistant professor of physics in the University of Minnesota; Dr. Francis Bitter, associate professor of the physics of metals in the Massachusetts Institute of Technology; Dr. Foster C. Nix, research physicist at the Bell Telephone Laboratories; Dr. Frederick Seitz, research physicist at the General Electric Laboratories in Schenectady, New York. Colloquia on the physical tools of use in metallurgy, and on the creep, elastic properties, internal friction, mechanism of hardening and fatigue in metals are also being held.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1145.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Kramers' Absorption Law in Astrophysical Problems

KRAMERS' well-known absorption law[1], long used by astrophysicists in their calculations of the opacity of stellar material, was first derived from classical mechanics and the correspondence principle, and may be stated thus:

$$\alpha_\nu = 0\cdot0104 \frac{Z^4 \lambda^3}{a_n n^3} g, \qquad (1)$$

where α_ν is the atomic coefficient of continuous absorption, Z is the effective atomic number, λ is the wave-length in cm., n is the quantum number, a_n is the statistical weight of the n^{th} state, and g is a factor very nearly unity.

Wave mechanical calculations have confirmed this result[2] for hydrogen, but have shown that it does not apply to hydrogen-like atoms[3], much less to other elements, as previously assumed. Laboratory measurements show that it is invalid for the alkalis[4] and not exact for X-ray absorption[5]. However, equation (1) has never actually been verified from observations on atomic hydrogen, which must be made at pressures sufficiently low for external conditions to have no effect[6].

It is not possible to measure the actual continuous absorption of light by hydrogen, but through Milne's fundamental relation[7] between photo-ionization and recombination, Cillié[8] has computed from equation (1) the relative numbers, p_n, of captures of electrons on the n^{th} level of a hydrogen atom in equilibrium with free electrons at an 'electron temperature', T_e. From an emission spectrum due to recombination we can determine the p's observationally from the following equations:

$$p_n = \sum_{r=n}^{\infty} K_{r,n} I_{r,2}, \text{ for } n > 2 \text{ (Carroll}^9\text{)}, \qquad (2)$$

p_2 = the number of quanta in the continuous emission at the head of the Balmer series. (3)

$I_{r,2}$ is the intensity of the $(r-2)^{\text{th}}$ Balmer line, and the K's are functions of the Einstein transition probabilities, which have recently been calculated up to $n = 14$ by Menzel and Pekeris[2].

Two published sources of Balmer emission intensities which might be used in equations (2) and (3) are measurements first in the solar chromosphere spectrum by Menzel and Cillié[10], and secondly in the spectra of several planetary nebulæ, measured at this Observatory[11]. Recently I have also measured intensities in the spectrum from the electrically undisturbed region of an electrodeless discharge in hydrogen. In the nebulæ and in the discharge it can be shown that the recombination of protons and electrons must account for almost the entire emission, and the electron temperatures have been measured (and found to be near 1000° K.). In the chromosphere, however, as Menzel and Cillié point out, the mechanism of line formation is uncertain. Furthermore, no use can be made of their results because (*a*) their "Balmer continuous emission" must include the intensity of unresolved lines (Menzel[12] lists more than 2·6 lines of intensity greater than "O" per angstrom in that region), and (*b*) there may be further errors due to the calibration and standardization.

In this investigation the carefully estimated observational errors are such that the values of p_n listed in the accompanying table must be accurate to about 15 per cent for the nebulæ and 5 per cent for the discharge. We are therefore justified in testing Kramers' law by comparing the observed p_n listed in columns 2, 3, and 4 with the theoretical values for $T_e = 1000°$ K. (If the transition probabilities $A_{m,n}$ used are in error, Kramers' law must similarly be so, since it was calculated by the same methods as the $A_{m,n}$.)

RELATIVE NUMBERS OF CAPTURES ON LEVELS OF THE H ATOM

	Observed p_n (1000° K.)			p_n from Kramers' law	
n	Discharge	Nebulæ		1000° K.	50,000° K.
2	0·012	0·675	0·039	21	37
3	17·9	—	40	13·5	17·6
4	10·0	10·0	10·0	10·0	10·0
5	5·53	5·9	5·0	7·5	6·2
6	2·62	3·7	2·0	6·2	4·2
7	1·19	—	—	4·9	2·9
8	0·725	(*NGC.* 7 62)	(*NGC.* 7027)	4·0	2·2
9	0·366			3·4	1·6
10	0·202			3·0	1·3

Not only are the observed ratios $p_3 : p_4 : p_5 :$ etc. found to differ from those predicted in column 5, but also $p_3 \gg p_2$ (a peculiarity also observed for the alkali atoms[13]), whereas by Kramers' law $p_3 < p_2$.

We are thus forced to conclude that the use of Kramers' law in astrophysical problems is unjustified. A more detailed account of this investigation will shortly be communicated to the Royal Astronomical Society.

Mechanism of the Primary Photodissociation Process of Organic Molecules

IN a recent letter to NATURE[1], Bergmann and Samuel advance a theory of photodecomposition of organic molecules according to which two bonds are fissured simultaneously, not by the splitting of two single bonds but by a transition to the repulsive state which corresponds to a reduction of valency of the central atom resulting from the re-formation of the s^2 group of this atom.

This conclusion is not new: it was shown in 1933 by Norrish, Crone and Saltmarsh[2] that the ketene molecule is decomposed photochemically according to the equation

$$CH_2{:}\overset{|}{C}O \rightarrow CH_2 + CO\ (^1\Sigma), \qquad (1)$$

and that the energy of the photolysing quantum (74 kgm. cal.) is insufficient to rupture the double bond (say, 167 kgm. cal.) unless the CO is liberated as normal carbon monoxide rather than as free carbonyl. Similar considerations were held to apply to the photolysis of diazomethane[3].

The idea was then tentatively extended to ketones[4,5]; for example,

$$CH_3COC_2H_5 \rightarrow CH_3 + C_2H_5 + CO\ (^1\Sigma), \qquad (2)$$

but it was emphasized that there was no evidence to show in these cases whether the two alkyl radicals are eliminated simultaneously or one rapidly after the other. Since then it has transpired that in the case of acetone the elimination takes place successively[6]; this was later confirmed more generally since in paraffinoid solution it was shown that the free radical RCO formed can be hydrogenated to aldehyde[7] at temperatures exceeding 60°C.

The apparent result of equation (2) is thus due to the instability of the acyl group, which at 60° and upwards readily decomposes:

$$R\overset{|}{C}O \rightarrow R + CO\ (^1\Sigma), \qquad (3)$$

presumably owing to the tendency of the carbonyl of the radical to revert to the repulsive singlet state.

These results have not been taken into consideration by Bergmann and Samuel, while the photolytic equations which they suggest are unsupported by evidence, and in some cases in disagreement with fact. All the evidence shows that ketones and aldehydes do not decompose by analogy with their equations. In the region of predissociation, formaldehyde yields molecular hydrogen and carbon monoxide in one act[8,9], while the αα dicarbonyl substance glyoxal decomposes according to the equation[10]

$$2HCO.CHO \rightarrow CO + CH_2OH.CO.CHO.$$

The decomposition of methyl glyoxal is analogous and diacetyl appears to be still more complicated, and none of the products can be derived from equations of the type suggested by Bergmann and Samuel.

It should be noted that so far as aldehydes and ketones are concerned, the heats of the reactions

$$RCOR \rightarrow R + R + CO\ (^1\Sigma),$$

$$RCOR \rightarrow R + R\overset{|}{C}O,$$

though at present suffering from some uncertainty, are not very different, and that the threshold of continuous absorption is not sufficiently precise to be correlated with either, even supposing they were known accurately.

The mechanism of the photodissociation of SnI_4 and BiI_3 was first elucidated experimentally by Terenin[11]. Samuel and Parti[12] employ a modified mechanism to explain the long wave-length limit of the absorption spectrum of CI_4. The good agreement they obtain is dependent upon an uncertain assumption about the ratio of the heats of formation of $CHal_2$ and $CHal_4$ and also upon the use of a value 156·2 k.cal. for the heat of sublimation of carbon. Reliable sources[13,19] now consider the latter to be about 124 k.cal., a value which would completely upset their agreement. This has already been pointed out by Cherton[14], and the same remark applies to their other calculations.

Finally, it cannot be too strongly urged that with polyatomic molecules the principle of Franck, Sponer and Teller[15] comes into operation, and that the onset of predissociation is properly shown by the threshold of fluorescence rather than by the threshold of diffuseness[16]. With formaldehyde the former is at about 3700 A., and the latter at 2750 A., while the photochemical yield is unity on both sides of the limit of diffuseness, and the products unchanged[17]. Herzberg and Franz[18] set the true limit of predissociation at a wave-length longer than 3000 A. No evidence in support of Bergmann and Samuel is therefore forthcoming in the case of formaldehyde.

Generalizations of the type advocated by Bergmann and Samuel are unsafe because of the uncertainty of the precise values of the energy of many chemical bonds, and also because of the doubt as to the proper interpretation to be put upon diffuseness in the spectra of polyatomic molecules. They cannot be safely accepted in the absence of supporting chemical evidence.

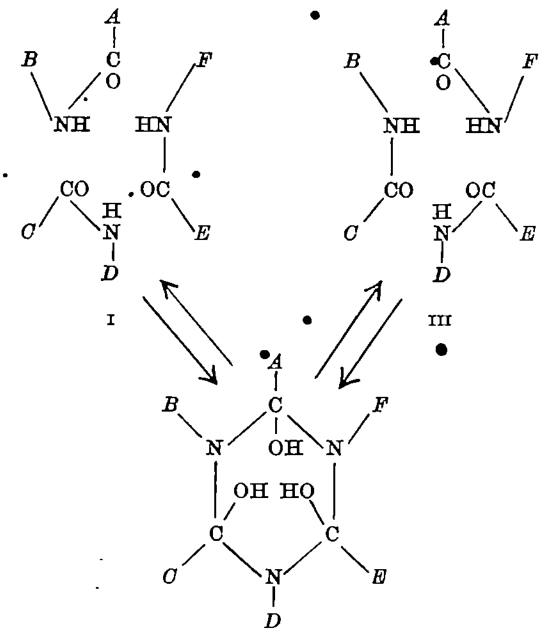
Possibility of the Formation of Cyclols from Simple Peptides

IN a series of communications in NATURE, Dr. D. M. Wrinch[1] has put forward a new hypothesis on the structure of certain proteins—the 'cyclol-theory'. According to this, peptide chains should be capable of uniting to form two- and three-dimensional nets, three peptide residues forming a ring as in II:



A, *C*, and *E* represent residues of the type R.CO.NH.CHR-; *B*, *D*, and *F* residues of the type R.NH.CHR.CO-.

Compounds of this kind (II) are unknown, and a consideration of the thermal data shows that it is improbable that they should occur in considerable quantity in equilibrium with free peptides. It seemed to us of interest to ascertain whether they occur even in minute quantities in tautomeric equilibrium with free peptides, and whether their presence could be demonstrated indirectly.

In the cyclol compound II, the residue *A* is united to both *B* and *F* in the same way. This compound may be formed by condensation of peptide *AB* with *CD* and *EF* (I → II), but also from the peptides *AF*, *ED*, and *CB* (III → II). In the reconversion of a cyclol to its peptides, therefore, not only should the original material be obtained but also a mixture of peptides: in this case, from those in I, those in III as well. In other words, the peptides must be able to exchange residues with one another if cyclols are formed (even in minimal quantity) in tautomeric equilibrium.

Glycyl *l*-leucine and *l*-leucyl glycine were mixed; these should have interchanged to form partially *l*-leucyl *l*-leucine and glycyl glycine if cyclol formation takes place at all. Observation of the optical activity showed, however, that no such reaction can be detected, either in neutral aqueous solution or in solutions of the chlorhydrates or of alkali salts. The rotation of equimolecular mixtures of both peptides was equal to the mean of the rotations of the two peptides (see accompanying table) and remained so for twenty-four hours. Any formation of *l*-leucyl *l*-leucine would have led to a considerable diminution in the rotation.

		neutral	acid	alkaline
$[\alpha]_D^{20°}$	*l*-leucyl glycine	+77·6	+44·3	+25·0
,,	glycyl *l*-leucine	−35·3	−34·1	−19·7
	mixture (observed) ..	+21·7	+5 2	+2·8
half rotation of *l*-leucyl *l*-leucine		+3·5	—	−6·7

Cyclol formation does not, therefore, occur under these conditions. This does not speak favourably for the 'cyclol-hypothesis'. It seems highly improbable that the nature of the peptide linkage may be so modified by lateral substituents, that a reaction which is entirely absent from simple peptides becomes possible in proteins.

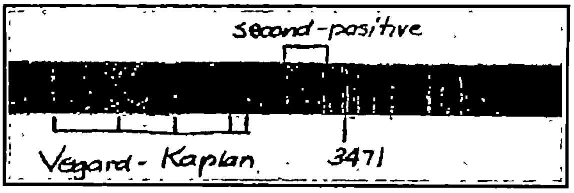
A New Nitrogen Line

RECENTLY[1], I reported the preliminary study of a nitrogen afterglow at high pressures, rich in the Vegard-Kaplan bands and containing a line at 3471 A. which was tentatively identified as the hitherto unobserved transition $^2P \rightarrow {}^4S$ in atomic nitrogen. That report was based on observations of the afterglow from two tubes, in one of which the nitrogen was purer and at a lower pressure than in the other. Further observations on these tubes has enabled us to study the variations in intensity of the Vegard-Kaplan bands and the new line, both with respect to pressure and to purity.

There is definite indication that the 3471 line increases in intensity as the tube approaches the pure nitrogen stage, and that its rise in intensity in one tube follows that of the intercombination bands, and that its fall with pressure in the other tube also follows these bands. The spectrum reproduced herewith shows the line-like character of this radiation, its extraordinary intensity relative to the normally strong second-positive bands, and the large intensity of the Vegard-Kaplan bands. There is also indication in these experiments of the increase with pressure of both the Vegard-Kaplan bands and the 3471 line. The enhancement of these relatively forbidden transitions with pressure is indeed a strange phenomenon, when one remembers that similar transitions in neutral oxygen and in various stages of ionization of oxygen and nitrogen are responsible for some of the strongest lines in the spectra of nebulæ. These nebular lines are strengthened at low pressures. In fact, it is generally agreed that low pressures are necessary for such forbidden transitions, and the present experiments are probably the first evidence to the contrary.



HIGH-PRESSURE NITROGEN AFTERGLOW PHOTOGRAPHED ON A SMALL QUARTZ SPECTROGRAPH. STRONG BANDS TO RIGHT OF λ 3471 ARE DUE TO CYANOGEN; OTHER WEAK BANDS DUE TO NO.

The absence of any of the forbidden transitions of non-ionized atomic nitrogen in the spectra of celestial objects appears to find its explanation in these experiments. More interesting for the physics of the upper atmosphere is the conclusion from these results that the Vegard-Kaplan bands, the 3471 line, and possibly other radiations in the light of the night sky, are emitted in the lower rather than in the higher regions of the upper atmosphere, perhaps so low as 50 km. This conclusion is based on the presence in the light of the night sky of a strong line at 3471 and of the Vegard-Kaplan bands. In fact, the spectrum reproduced here is an excellent reproduction of the light of the night sky.

The tube from which this plate was photographed is now rapidly approaching a pure nitrogen stage. The next two or three photographs should give us valuable information regarding the relationship between this line and the Vegard-Kaplan bands, as well as further proof that the line is characteristic of pure nitrogen.

[1] Kaplan, NATURE, 141, 645 (1938)

Possible Presence of Metastable Atoms of Nitrogen (^2P) in the High Atmosphere

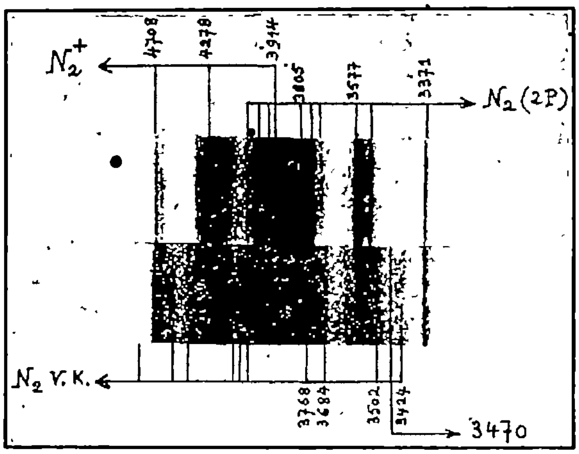
DURING a stay at the Tromsø Observatory, I studied systematically the spectrum of different forms of auroras (arcs, draperies, clouds, corona, etc.). One hundred spectrograms were thus obtained in the autumn of 1937. The analysis of these data is now being carried out, but some important facts are already apparent.

The spectrum of the bright region of an intense aurora (arc, draperies, corona) always offers the same general aspect. Outside the red and green lines of O I, the bands of the three systems of nitrogen, N_2^+, $N_2(1P)$ and $N_2(2P)$ only are observed (see upper spectrum, photographed on a Guilleminot Superfulgur plate having no sensitivity in the green). A very great over-exposure discloses practically no new radiation. The luminescence can be reproduced by submitting nitrogen to an electronic bombardment with a proper accelerating potential[1].

Some diffuse auroras behave in a completely different way. If the exposure is sufficient, their spectrum contains, with the lines and bands previously mentioned, a relatively great number of other radiations, generally weak and difficult to identify. However, these radiations may show so large an increase in intensity that their study becomes easy. It may be ascertained that they are the nitrogen bands $A \rightarrow X$, known as Vegard-Kaplan bands. The heads located at 3424, 3502, 3684, 3768, 4045, 4073, 4171, 4425 and 4535 A. are particularly distinct; these bands are plainly degraded toward the longer wavelengths (see lower spectrum).

With the Vegard-Kaplan bands, and evolving in the same way, an intense and sharp line always appears near 3470 A. (3470·3 A., according to the best measurements). Its appearance is such that it is easily distinguished from the neighbouring bands, and that any trial of identification with the 3469 $N_2(2P)$ band is impossible. As no other plausible interpretation comes to the mind, it seems reasonable to admit the presence of the atomic nitrogen line $^2P \rightarrow {}^4S$, the computed position of which is also 3470 A. This attribution is in perfect agreement with the recent observation by Prof. Kaplan[2] of a high-pressure afterglow in nitrogen, giving near 3470 A. a strong line associated with the Vegard-Kaplan bands.

As Prof. Kaplan suggests, the radiation reported at 3471 A. in the night sky light (Dufay, Gauzit) is perhaps also the nitrogen line $^2P \rightarrow {}^4S$. But the spectrum of the sky is so complex that it is difficult to give weight to this attribution. On the contrary, the simultaneous presence of the 3470 line and of the Vegard-Kaplan bands in the aurora and in the afterglow, with a similar evolution, seems to prove that the radiations emitted in both cases have the same origin. The fact is obvious for the Vegard-Kaplan bands; it is highly probable for the 3470 line. If we consider that active nitrogen is doubtless a mixture of metastable nitrogen molecules and atoms, the attribution of the 3470 line to the transition $^2P \rightarrow {}^4S$ becomes quite normal.



SPECTRA OF BRIGHT AURORA (*above*), DIFFUSE AURORA (*below*).

The presence of nitrogen atoms (^2P) in the auroral region must then be taken into consideration, and we may expect to find also the lines corresponding to the transitions $^2P \rightarrow {}^2D$ (λ = 10,400 A.) and $^2D \rightarrow {}^4S$ (λ = 5206 A.). The first one occurs in a part of the spectrum which has not yet been explored. The other, which is much less probable, was not recognized in the aurora or the light of the night sky. A more complete and thorough analysis of the two spectra and, above all, the study of the 3470 line by the interference method, should give the definitive solution of the problem.

The actual state of our knowledge, however, permits us to conclude that, in the aurora, the mechanism of excitation includes probably the two following stages:

(1) An electronic bombardment, which is the primary phenomenon and produces the permanent radiations of the spectrum.

(2) An afterglow, similar to that of Kaplan, giving rise to the nitrogen bands $A \rightarrow X$ and to the 3470 (N I, $^2P \rightarrow {}^4S$) radiation. This second process seems very important in certain diffuse auroras.

Quantitative Measurement of Vitamin B_1 by the Thiochrome Reaction

IN 1936, Jansen[1] first suggested that vitamin B_1 could be measured quantitatively by conversion into thiochrome with alkaline ferricyanide and measurement of the fluorescence of the thiochrome. Since that time, information has been collected on the use of this method for the assay of vitamin B_1 in urine[2,3,4] and in other materials including foodstuffs[5]. Evidence, however, is now accumulating that, although results which compare closely with the biological assay can be obtained with crystalline vitamin B_1 and acid-clay adsorbates of the vitamin when the precautions described elsewhere[5] are exercised, the assessment by the chemical method on certain foodstuffs is significantly lower than the biological results.

Biological assay (Int. units per gm.)	Chemical assay (Int. units per gm)	Chemical/Biological
9·5 10 0 10 0 10·0 10 5 Avg. = 10 0	6·8 6·3 7 9 8·1 7 6 Avg. = 7 3	73 per cent
11 0 11 0 11·0 11 2 11 2 11·2 11·5 11·5 11 5 Avg. = 11 2	6·8 7 2 8 1 6·7 6 9 8 6 6·2 6 4 6 4 Avg. = 7 0	62 ,,
12·0 12·0 12 0 12 5 12·5 12·5 12 5 12 5 Avg. = 12 3	5 1 6·5 7 6 6 7 7 2 7·3 7·5 8 6 Avg. = 7 1	58 ,,
14·0 15 0 15 0 16 0 16 2 20 0 Avg. = 16·0	6·8 6 7 6 2 6 6 5 9 8 1 Avg. = 6 7	42 ,,

The accompanying table gives the comparative figures for vitamin B_1 in twenty-eight samples of wheat embryo. The biological assays were carried out by Dr. A. Z. Baker of this laboratory by the bradycardia method[6]. A minimum of six rats was used in each case.

Other foodstuffs appear to give similar results. Certain proprietary yeast preparations, for example, contain substances with a considerable blue fluorescence, and frequently no additional intensity of fluorescence develops after ferricyanide oxidation. The chemical assay therefore appears to be zero, although the usual activity of 6–10 international units per gram of vitamin B_1 is known to be present.

Vitamin B_1-pyrophosphate, which appears to be of fundamental biological significance, is insoluble in isobutyl alcohol[7] and is not therefore included in the chemical assay. It has also recently been suggested[8] that vitamin B_1 exists combined with protein, in which form it might be expected to be difficult to extract chemically from tissues. Therefore the quantitative recovery of crystalline vitamin B_1 added to a substance under analysis cannot be taken as evidence that the results obtained for that substance by the thiochrome method are a complete measure of the vitamin activity of the material.

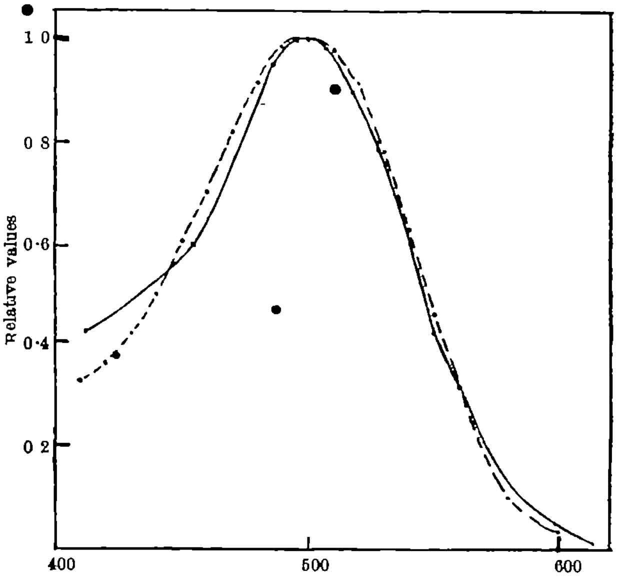
Scotopic Luminosity Curve and the Absorption Spectrum of Visual Purple

MANY attempts have been made to explain the discrepancy between the scotopic luminosity curve and the absorption spectrum of visual purple. Recently, Dartnall and Goodeve[1] have applied the Stark-Einstein law in order to express the luminosity curve in terms of quanta and have shown that the resulting correction was insufficient.

A consideration of various additional possible factors, such as Kundt's rule and the retinal grey, which might explain the discrepancy, convinced me that the scotopic luminosity curve should be corrected for the absorption spectrum of the ocular media. It is known that this spectrum varies considerably with the genus of animal, and for man has not hitherto been determined through the visible spectrum. Recently, however, in collaboration with E. F. McCarthy, I completed measurements of the absorption spectrum in the wave-length range 400–820 mμ for the refractive media of the human eye. Preliminary reports[2] of this work have already been made and a paper giving the results will appear shortly[3].



– – – – ABSORPTION SPECTRUM OF VISUAL PURPLE OF THE FROG (LYTHGOE).

——— SCOTOPIC RETINAL LUMINOSITY CURVE (LUDVIGH AND MCCARTHY).

It will suffice here to give the results obtained by applying the Stark-Einstein law and data on the young normal human eye to transform a scotopic *ocular* luminosity curve into a very different curve, namely, a scotopic *retinal* luminosity curve. This permits the comparison of the absorption spectrum of rhodopsin with the *retinal* luminosity curve instead of with the *ocular* luminosity curve.

The accompanying graph shows the agreement of the transformed data of Hecht and Williams[4] with Lythgoe's data[5] on the absorption spectrum of visual purple. The conclusions drawn from this curve are: (1) The retinal sensitivity for blue is much greater than has been previously assumed. (2) It is not necessary to invoke Kundt's rule, as did Hecht and Williams[4], to explain the discrepancy between the two sets of data. (3) It is not necessary to assume that, because of their relatively high absorption coefficients in the blue, solutions of visual purple recently prepared[5,6,7] are different from those of the solutions of visual purple present, under low illuminations, in the intact retina *in situ*.

Cosmological Theory

ON the assumption that the red-shifts observed in the spectra of the extra-galactic nebulæ are due to a Doppler effect, Hubble's observations indicate that the nebulæ are receding from us with velocities proportional to their distance from us. Thus at each point in space there exists a characteristic velocity and a preferred time-axis in four-dimensional space-time, this preferred time-axis being that with respect to which the matter at the point is at rest.

This absolute time and characteristic velocity, which varies from point to point in space, has formed the starting point of two cosmological theories, one proposed by Milne[1] and the other by Dirac[2]. Milne introduces the assumption called the 'cosmological principle', which asserts that the universe is everywhere uniform and has spherical symmetry about every point for an observer moving with the characteristic velocity at that point. Milne's theory further requires that all constants appearing in the theory are to be dimensionless.

Dirac, while accepting the cosmological principle, rejects the 'dimensional hypothesis' of Milne and proposes in its place the assumption that "any two of the very large dimensionless numbers, of the order of 10^{39} and 10^{78}, which appear in Nature are connected by a simple mathematical relation in which the coefficients are of the order of magnitude unity".

The theories of both Milne and Dirac lead to the conclusion that there are two time-scales of importance, one for atomic phenomena and the other for ordinary mechanical phenomena. If we denote the measure of a small interval of time on the first of these scales by dt and the measure of the same interval of time on the other scale by $d\tau$, then Milne's theory requires that

$$dt = (t/t_0)d\tau, \qquad (1)$$

where t is the epoch at which the two measures are made and t_0 is the present epoch, that is, the present age of the universe. In place of (1), Dirac's theory requires the relation

$$d\tau = tdt, \qquad (2)$$

where, in both (1) and (2), the t-scale of time is the natural scale for atomic phenomena and the τ-scale is that for macroscopic phenomena to which general relativity applies.

On Milne's theory, an atomic clock keeps t-time while a planetary clock keeps τ-time, and the laws of Nature and the equations of motion have their usual form when expressed in τ-time. Since a velocity has the same measure on both *time-scales, the t-measure and the τ-measure of a distance have different values*.

A little more than a year ago, I investigated the consequences of the assumption that *the measure of a distance is the same on both time-scales*, and hence a velocity measured in t-time differs from the value obtained when a τ-clock is used. The laws of mechanics, the equations of motion and general relativity are all assumed (as results from Milne's theory) to hold in τ-mechanics. In fact this requisite *defines* τ-time. The first consequence of this theory is that the proper energy of an elementary particle mc^2, which is constant in τ-mechanics, varies inversely as the square of the epoch in t-mechanics. If we now *define* the number of elementary particles in the universe as the total energy of the universe divided by the element of energy mc^2, and assume that the total energy of the universe is conserved, we have the result that the number of particles in the universe varies as the square of the epoch, a suggestion which was originally put forward by Dirac[3].

Without the introduction of any further assumptions and without any appeal to general relativity, the results below follow.

$$GM = kc^3t,$$

where G is the gravitational constant, M the mass of the universe, c the velocity of light and k a dimensionless constant which is taken as unity. This shows that the gravitational constant depends upon the total amount of matter in the universe—a conjecture which has often been made in the past. The total number of particles in the universe is given by

$$N = \tfrac{1}{2}t^2,$$

where t is to be expressed in atomic units e^2/mc^3. The present age of the universe is found below to be 2×10^9 years. This gives the value $2 \cdot 31 \times 10^{79}$ for N, which is of the same order as the value obtained by Eddington[4].

The radius of the spherical model of the universe is found to be $R = ct$, which is *constant* in both t-mechanics and τ-mechanics. The value is $1 \cdot 89 \times 10^{27}$ cm., which is of the same order as the radius of the Einstein universe, namely, $1 \cdot 23 \times 10^{27}$ cm. On this theory the red-shift in the spectra of the extra-galactic nebulæ is due, not to a Doppler effect, but to a decrease in the velocity of light in t-time. The formula obtained for the red-shift is

$$\frac{d\lambda}{\lambda} = \varepsilon^{d/t_0} - 1,$$

where d is the distance of the nebula in light-years and t_0 is the present age of the universe. When d is small compared with t_0, this reduces to the usual linear relationship $d\lambda/\lambda = d/t_0$. Hubble's empirical formula is $d\lambda/\lambda = 5 \cdot 71 \times 10^{-10}d$, and thus $t_0 \sim 2 \times 10^9$ years.

The theory also gives the equation

$$m = \frac{\sqrt{2}}{137}\,\frac{h}{2\pi c}\,\frac{\sqrt{N}}{R}$$

for the relation between the mass m of an electron and the number of particles in the universe at the present epoch. This should be compared with Eddington's equation[4]

$$m_0 = \frac{h}{2\pi c}\,\frac{\sqrt{\frac{3}{2}N}}{R},$$

where m_0 is the mass of a neutral particle of the comparison fluid. From Eddington's theory, $m_0 \sim 136\ m$.

Finally, the theory leads to the uncertainty relation in the form

$$\Delta p\,\Delta q \sim \frac{h}{4\pi},$$

and thus links quantum theory with cosmological theory.

It thus appears that a reasonable and self-consistent theory of cosmology can be built up from the initial assumption that a planetary or pendulum clock measures time at a different rate than does an atomic clock, the relationship between the two measures of a small interval of time being given by (1). The theory is based essentially upon this single assumption, together with the principle of the conservation of energy. An observer, measuring time by an atomic clock, concludes that, although the total energy of the universe remains constant, the number of elementary particles as defined above is increasing as the square of the epoch, and that there exists a definite epoch of creation. An observer, measuring time by a rotating planet, finds the usual laws of mechanics and the Newtonian and relativistic equations of motion to hold good. He concludes that the number of particles in the universe is constant, and that the universe has existed, though not necessarily in its present configuration, for an infinite time.

Thermal Expansion and 'Co-operative Phenomena'

A RECENT investigation[1] on the dielectric polarization of a ketone near the melting point shows a considerable difference between the temperature—polarization curves at constant volume and at constant pressure. The change of volume thus appears to have a considerable effect on the free rotation of molecules in the lattice, which is a 'co-operative phenomenon'.

It seems not unlikely that volume changes might be of importance in other 'co-operative phenomena'. The order-disorder transition of β-brass is experimentally investigated at constant pressure. The existing theories take no account of the experimentally observed change of volume. Actually, the theoretical maximum of specific heat is too small, and the slope of the temperature—specific heat curve at temperatures below the maximum is about 1/15 of the experimental value, which discrepancy may be due to the neglected expansion.

In order to test this view, I carried out a calculation of the specific heat at constant pressure. The energy of a zinc-copper pair is assumed to be proportional to the square of volume change. A similar assumption is made for the mean energy of copper-copper and zinc-zinc pairs, their minimum energy lying at higher volumes than the minimum of copper-zinc. In each of these parabolic energy curves a parameter is introduced. The method of calculation is similar to the theory of Bragg and Williams.

The specific heat—temperature curve obtained can be adjusted so as to give good agreement with experiment. It appears to be not very sensitive relative to variations of one parameter. The assumed dependence of copper-zinc energy on volume is compatible with the energy as calculated from the compressibility of brass and the observed expansion. By this calculation, the details of which are to be published shortly, it is shown that even a small expansion may have considerable effect on the specific heat.

Occurrence of *Zelleriella*, an Opalinid Ciliate, in South Africa

THE fauna and flora of the southern extremity of Africa present a number of striking resemblances to those of South America on one hand and Australia on the other. I have recently come across an unexpected addition to this number in finding *Zelleriella* in the recta of two different species of *Rana* from the neighbourhood of Cape Town. According to Bigalke[1] there appear to be no records of the establishment of any exotic amphibia anywhere in the Union of South Africa and we must therefore assume that the Cape Zelleriellas are indigenous. The following zoogeographical data suggest their significance.

(1) *Zelleriella* is the dominant Opalinid of tropical America, its principal hosts being the toothed bufonids (Cystignathidæ or "Leptodactylids"). Elsewhere, except for one questionable record from a toad from "Asia", they have only been found in Australia, where their hosts are exclusively leptodactylids.

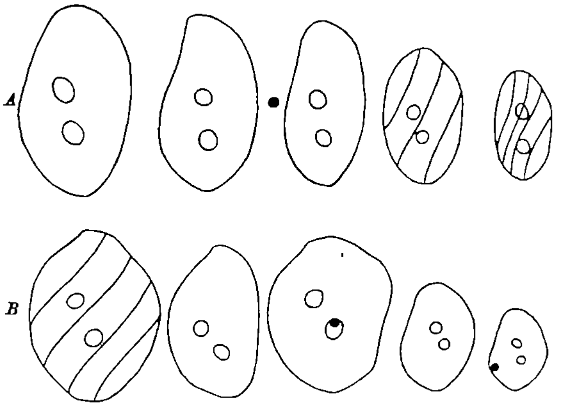
(2) The toothed bufonids also occur at the present day only in Central and South America and in Australia.

(3) From these facts Metcalf[2] concludes that the leptodactylids originated in Argentina–Patagonia and crossed to Australasia by an early Miocene land-bridge. *Zelleriella* was originally a parasite of these toads and migrated with them, but infected other amphibia as it spread northwards in America. The recent discovery in India of a Miocene Cystignathid closely resembling the present-day Australian genera, however, weakens this argument[3].

(4) The Cape Zelleriellas apparently do not extend far towards the north, for none were found by Fantham[4] in his extensive investigation of the parasites of amphibia in the Transvaal. In view of their ability to live in a variety of amphibian hosts, it is difficult to believe that these ciliates can have come from the north without leaving representatives in other parts of Africa. Their presence in the Cape consequently is most easily explicable on the hypothesis of former land connexions with the other southern continents, in which case their history must

extend back to late Secondary times. As no toothed bufonids occur in Africa, the question of their original hosts in this continent is a puzzle on any hypothesis.

(5) The distribution of the other genera of Opalinids also fits in with this idea. *Protoopalina* is by far the commonest member of the family throughout Africa, and it is noteworthy that the species regarded by Metcalf as archaic are those found in Patagonia, Papua, Australia and Africa. *Opalina* and *Cepedea*, though otherwise practically cosmopolitan, have not been recorded from either Australia or the Cape. Both occur in Central Africa, and Fantham[4] (1923, 1924, 1927, 1931) found *Opalina sudafricana* very occasionally in *Bufo regularis* at Johannesburg. (Incidentally, if Metcalf's view is correct that the *Opalinæ angustæ*, to which this species obviously belongs, form a natural subdivision of the genus, this record is a curious one. The *Opalinæ angustæ* are characteristic of the tree-frogs of North America, only one species, *O. obtrigona*, having crossed over to Europe and Asia, to which it was carried by its host, *Hyla arborea*.) In Africa, it seems, all these ciliates spread much less freely than their hosts.



A. Zelleriella [*africana A*] from *Rana delalandii*

B. Zelleriella [*africana B*] from tadpole of *Rana fuscigula*. Mag. approx. 120 diameters.

(6) The Ranidæ are an Old World group showing their greatest diversity of type in Africa. Only one species has penetrated to North America, and this has been found infected with *Zelleriella* in California, the northernmost limit of the parasite.

(7) The common frog for class purposes here is *Xenopus*, a member of the Pipidæ (Aglossa). This family is at present found only in South America and Africa. It is, however, regarded as of northern origin, and no Zelleriellas have been found in any member of it.

In the present state of our knowledge, it is impossible to subdivide the Zelleriellas into species, and we cannot therefore say whether the Cape forms are more nearly akin to those of Australia or of America. They have been found once in *Rana delalandii* and once, from a different locality, in a tadpole of *Rana fuscigula* (I am indebted to Dr. W. Rose for the identification of the frogs). The two forms differ somewhat and may be referred to as *Z.* [*africana A*] and *Z.* [*africana B*] respectively, the brackets being used, as by Metcalf, to indicate that the names are for reference only and do not necessarily imply specific status. In neither is there any clear demarcation of ectosarc from endosarc, and the chief differences are that form *B* is broader and less regular in outline than form *A* and that the cytoplasm of *A* is vacuolated whereas that of *B* is granular.

The principal measurements of adult specimens are :

	Form *A*	Form *B*
Greatest length	124μ — 213μ	92·5μ — 167μ
Ratio : length/breadth ..	1·72 — 2·07	1·28 — 1·65
Nuclei	12·5 × 15·6μ — 20·3 × 23·1μ	9·6 × 10·6μ — 19·7 × 22·2μ
Distance between rows of cilia	1·3 — 2·0μ	1·85 — 2·6μ

Typical outlines are shown in the accompanying figures, the direction of the rows of cilia being indicated in a few cases.

Irregular Mitosis and Meiosis induced by Acenaphthene

PARTICLES sublimed from the crystals of the biologically active substance which, according to Shmuck, induced morphological peculiarities similar to those induced by colchicine, were used for altering the normal procedure of the mitotic and meiotic processes.

Germinating seeds from cereals and grasses (wheat, rye, oat, barley, maize, rice. *Festuca, Lolium,* etc.), covered by crystals of acenaphthene for 4–8 days, grow slowly, forming very thick and short roots and leaves. Leguminous plants (*Vicia, Ervum, Lathyrus, Medicago,* etc.) reacted after a longer exposure (6–12 days). Species of Compositæ tested occupied a position between these two groups of plants.

Mitosis in treated seedlings proceeds abnormally. The activity of the factors responsible for the arrangement of the chromosomes in a regular equatorial plate and for the formation of the achromatic figures (spindles) is inhibited. The chromosomes do not become arranged in a regular equatorial plate. They divide but do not move toward the poles, thus forming polyploid nuclei. Sometimes the chromosomes become abnormally spread into the cytoplasm, giving rise to polynucleate cells. The latter might lead to heteroploidy.

Branches with floral buds of nine *Nicotiana* species were treated with acenaphthene particles. In buds in which meiosis proceeded, abnormal processes were induced. One usually finds during the meiotic metaphase the expected number of bivalent chromosomes, but they do not become arranged on a regular equatorial plate ; they occupy positions similar to those of diakinesis. The chromosomes divide without being 'pulled' to the poles. They spread abnormally into the cytoplasm in groups of several chromosomes or even as single chromosomes. This conditions the formation of variable numbers of nuclei at the end of the second division. Each nucleus or group of nuclei is separated during cytokinesis, thus forming a variable number of microspores with one or more than one nucleus. Consequently the microspores have unequal chromosome numbers. This gives rise to a large percentage (50–100 per cent) of abortive pollen. The viable pollen grains are equal in size, containing unequal chromosome numbers. They can give rise to plants with aberrant chromosome numbers.

Decomposition Reactions of Organic Compounds in the Gaseous State

PERHAPS Prof. Hinshelwood will excuse me if I suggest that no useful purpose is effected by discussing the treatment of isolated sets of experimental data on the lines indicated in his letter in NATURE of June 4, p. 1010. Space would not permit me to go into the question in detail; and to counter with similar illustrations from his own work would be waste of time. Doubtless our methods are very far from perfect, and I may say that after, not merely twelve, but forty-two years' experience of work with gases, I find that the difficulties are such that the greater part of the work of most labourers in this fascinating field washes out.

That we hold differences of opinion as to the way in which problems in kinetics of gas reactions should be handled is well known. I do not suppose that anyone who is not interested in the subject reads my papers, or those of Prof. Hinshelwood; but it is scarcely reasonable to imagine that anyone criticize his work on the basis of hearsay information regarding mine. If anyone does so, or *vice versa*, does it matter ?

Points from Foregoing Letters

FROM his measurements of intensities in the Balmer emission spectrum due to recombining protons and electrons in the gaseous nebulæ and in an electrodeless discharge tube, T. L. Page concludes that Kramers' absorption law is invalid for hydrogen. The use of this law in astrophysical problems is therefore unjustified.

Prof. R. G. W. Norrish enumerates several objections to the theory put forward by Bergmann and Samuel to account for the photo-decomposition of organic molecules by the simultaneous fissure of two bonds, that is, by a reduction of valency of the central atom.

Prof. K. H. Meyer and W. Hohenemser find that the two peptides glycyl *l*-leucine and *l*-leucyl glycine do not interchange their constituent groups in solution. From this they infer that, under the conditions of the experiment, no molecules of the cyclol type are formed.

Further studies of the high-pressure nitrogen afterglow leads Prof. J. Kaplan to the view that the new 3471 line is closely related in its intensity variations with the Vegard-Kaplan bands. The spectrum reproduced is a good laboratory reproduction of the night sky spectrum and suggests the hypothesis that the light of the night sky originates low in the upper atmosphere.

Photographs of spectra of bright and diffuse auroras are submitted by R. Bernard. The spectrum of the diffuse aurora shows an intense sharp line at 3470 A. This may be ascribed to atomic nitrogen ($^2P \rightarrow {}^4S$), and the author concludes that the mechanism of excitation in the aurora probably includes two stages: an electronic bombardment producing the permanent radiations of the spectrum; and an afterglow giving rise to the nitrogen bands.

The chemical assay of vitamin B_1 gives lower values than the biological assay, according to results obtained by Dr. M. Pyke. The author ascribes this to incomplete extraction.

Using data of Hecht and Williams on the absorption of visual purple, and taking into consideration the absorption spectrum of the ocular media, Ludvigh and McCarthy have obtained the retinal luminosity curve for scotopic (twilight) vision. Comparison of this curve with that for the absorption spectrum of visual purple of the frog (Lythgoe) leads E. Ludvigh to revise some of the previously accepted views and to conclude that the retinal sensitivity for blue is much greater than has been previously assumed.

From the initial assumption that a planetary or pendulum clock measures time at a different rate than does an atomic clock (as explained by Milne), also accepting the principle of the conservation of energy and assuming that the measure of a distance is the same on both time-scales, Dr. F. L. Arnot deduces that for an observer measuring time by an atomic clock the number of particles in the universe varies as the square of the age of the universe (2×10^9 years). On the other hand, using the pendulum time scale, the number of particles in the universe appears constant, but the age of the universe becomes infinite.

Dr. R. Eisenschitz announces that he has calculated the specific heat of brass at constant pressure, and that the 'specific heat - temperature' curve obtained can be adjusted so as to give good agreement with experiments. The assumed dependence of the energy of a copper-zinc pair on volume is compatible with the energy as calculated from the compressibility of brass and the observed expansion.

The presence of *Zelleriella*, a minute parasite of certain toads and amphibians of South America and Australia, is reported by Dr. H. Sandon from South Africa. This parasite is not found in North Africa or Asia, and its presence in South African frogs lends support to the hypothesis of former land connexions between the southern continents.

Germinating seeds of dry barley and other cereals, etc., covered with crystals of acenaphthene for a few days, show changes in the type of their growth, according to Prof. D. Kostoff. These changes are found to correspond to abnormal behaviour of the chromosomes during the process of division of the cells. The activity of some factors responsible for the arrangement of the chromosomes during mitosis and meiosis is apparently inhibited.

Research Items

Bushmen and Hottentots

In the course of an investigation of a quantity of skeletal material, adult and infant, from burials in the rock-shelter on Oakhurst Farm, George, Cape Province, South Africa, excavated by Mr. A. J. H. Goodwin (see page 1151), Prof. H. R. Drennan has found it necessary to define the characteristics by which the Bushman and Hottentot types are differentiated (*Trans. R. Soc. S. Africa*, 25, 3, 1938). A comparison of the skeletal material from Oakhurst and the Matjes cave, both associated with the Wilton stone age culture, leads to the conclusion that the Hottentot, instead of being a Bushman-Bantu cross, as has been held generally, may be the product of an evolution from a 'Wilton race', the larger head and greater stature in comparison with the Bushman being an inheritance from a Boskop or Boskopoid type. The Wilton race, it is generally recognized, has strong affinities with late palæolithic man in Europe and northern Africa. As regards the special features of the Hottentot skull, as distinguished from that of the Bushman, it tends to be 5–15 mm. longer, but as there is no proportionate increase in breadth, and often a diminution, the majority are dolichocephalic, whereas a majority of the Bushman skulls are mesaticephalic. The Hottentot skull is consequently more an elongated oval than of the marked Bushman pentagonoid form. The vault is definitely higher, the breadth-height index bringing out the difference very strongly. The width of the face is only slightly greater than in the Bushman, in keeping with the narrowness of the cranium; but the length is definitely increased in relation to the length of the base of the skull, giving a downward extension of the jaw which has the appearance of prognathism, whereas it is really 'subgnathism'. The orbital index is usually lower than in the Bushman. Both races are platyrrhine. The mandible of the Hottentot is distinctive, being more massive and much longer, but it is not much wider, and therefore has a much higher mandibular index. The ramus is also more robust, and even wider in relation to the height than the Bushman ramus.

Study of Life and Climatic Relations

Miscellaneous Publication No. 280 of the U.S. Department of Agriculture, dated January 1938, is a quarto brochure of 188 pages on "Bioclimatics. A Science of Life and Climatic Relations". Its author, Dr. A. D. Hopkins, was formerly an official entomologist but resigned in order to devote his time to research on this subject. The purpose of this publication is to give the results of prolonged studies made by the author on the principles of life and climatic relations, and their application to agriculture, with the hope that specialists in different sciences will adopt such as may be applicable to their own lines of work. The bioclimatic zone and zonal types of a place, area, or local region are the most reliable indexes to the species of animals and plants, and to the types of agriculture, that are best adapted to the local conditions. Under the requirements of the bioclimatic law, the phenomena of life and climate should be equal, under equal influences at the same level, across the continents along lines which depart from the parallels of latitude at the assumed constant rate of 1° of latitude and 5° of longitude. These lines are termed isophanes. Since, however, the influences of local or other factors are never equal, departures or variations of the observed effects from the requirements of the law must occur. Such variation as determined by bioclimatic methods and expressed in units of time, temperature or distance serve (*a*) as measures of the relative intensity of the modifying influences and (*b*) as indexes to the interpretation of causes and factors and to the prediction of bioclimatic elements at any given geographical position. It is stated that the laws, principles, systems and methods as outlined in these pages, taken in conjunction with the tables, maps and test examples, enable the application of bioclimatic principles to be made to many branches of economic biology and agriculture.

Immature Stages of Aquatic Diptera

Prof. O. A. Johannsen completes his study entitled "Aquatic Diptera" in Memoir 210 of the Cornell University Agricultural Experiment Station, which comprises Parts 4 and 5 of the series. Part 4 deals with the large subfamily Chironominæ and Part 5 with the family Ceratopogonidæ. Many additions to knowledge of these two groups have been made in recent years, especially by European workers. The results have made it evident that in the Chironominæ the immature stages offer fewer and less sharply marked characters than do the adults, and considerable difficulty, therefore, attends the identification of these stages. In this connexion, the keys to the genera and species together with the accompanying figures of larval and pupal characters should prove a useful aid. In the Ceratopogonidæ, it will be noted, the few terrestrial forms are also included in order to make the account more complete. The part dealing with this family is written by Miss Lilian C. Thomsen.

Crustacea and Pycnogonida of the John Murray Expedition

Dr. M. Ramadan describes the Astacura and Palinura and Dr. W. T. Calman the Pycnogonida of the John Murray Expedition 1933–34 (British Museum (Natural History). Scientific Reports, 5, No. 5 and No. 6; 1938). Only ten species of Astacura and Palinura were collected, one of which, *Puerulus sewelli*, is new. There are two appendixes to this part, one on the luminosity of Penaeidæ, in which the photophores of *Hymenopenaeus debilis* are described, and the other on the structure of the ocular peduncles in deep- and shallow-water forms of the Penaeidæ. Comparison of the ocular peduncles in deep- and shallow-water penaeids shows that the simplest form of peduncle is found in the deep-water forms, and as a rule the cornea is hemispherical, whilst a complex peduncle and reniform eye occur in the shallow-water forms. Fourteen species of Pycnogonida were obtained by the Expedition, no fewer than six of which are new. *Colossendeis angusta* from deep water in the Gulf of Aden has an extremely wide distribution, perhaps world-wide, always in cold water and (except in the Arctic) at great depths. Lieut.-Colonel Seymour Sewell is of the opinion that the two specimens captured without doubt came along with the Antarctic bottom drift up the east coast of Africa or else with the deep Atlantic water that enters the Indian Ocean round the Cape of Good Hope.

Autecology of *Zostera*

T. G. TUTIN has recently issued an interesting discussion of the growth and habitat of *Zostera* in connexion with its curious disappearance from many Atlantic localities, first from the American seaboard in 1931 and then a year or two later from its European localities (*New Phytol.*, 37, No. 1, 1938). The plant was so reduced in many cases as to affect seriously the distribution of other marine life, such as fishes and wild game birds; in Canada alone the annual financial loss from its reduction was conservatively estimated at some £30,000. Two parasites have been identified in the diseased patches in both America and Europe, a *Labyrinthula* and a fungus *Ophiobolus halimus*, but Mr. Tutin's conclusion is that these parasites have probably been generally present and cannot be assigned a major role in the widespread disappearance of the plant. He points out that the sunshine deficiency in the year 1931–32 in the British Isles amounted to some 20 per cent below normal, that no year in the previous ten years showed a deficiency approaching this and that the plant as a result was less vigorous and succumbed more readily to parasites that were always present. The widespread disappearance on the American seaboard at almost the same time is regarded rather as a coincidence than as evidence of the operation of a parasite the activities of which have spread a year later across the Atlantic. Recovery may depend upon seed propagation, as seedlings are free from the parasite and may be expected in that case to be slow in many localities where temperature conditions especially are not favourable to flowering, seed production and germination. The same causes might explain the fact that the plant still flourishes in its Mediterranean localities, for there the habitat is suitable to propagation by seed.

Growth-Promoting Substances in Horticultural Practice

A VERY useful paper by Dr. M. A. H. Tincker (*J. Roy. Hort. Soc.*, 63, Pt. 5, 210; May 1938) gives timely results of a number of growth-promoting substances upon the rooting of a wide variety of cuttings. β-indolyl acetic acid, α-naphthalene acetic acid, phenyl acetic acid, iso-indolinone and indolyl butyric acid have been used, and various methods of application have been tried. The most suitable treatment appeared to be the standard method of placing prepared cuttings with their bases in a solution of the substance for 24 or 48 hours. A certain amount of success was also obtained by the application of solutions to the rooting medium. The use of lanolin pastes containing the growth-promoting substances was deemed unsuitable for garden routine, though useful for unilateral application in experimental work. An interesting fact is that the polarity of root cuttings of *Anchusa italica* was influenced by treatment with α-indolyl acetic acid, and the results in general show a useful increase in facility or strength of rooting. Extensive though this paper is, the results require to be multiplied exceedingly. Dr. Tincker reports, for example, considerable success with ten varieties of *Pelargonium zonale*, following treatment; but the increasing experience of gardeners suggests that *Pelargonium* varieties respond somewhat irregularly to treatment with growth-promoting substances, and it is conceivable that with further varieties, or with other substances, Dr. Tincker would have had different results.

A Smut Disease of Brassicaceous Crops

CABBAGES and allied plants are subject to several destructive diseases, but yet another pathogenic fungus has recently been added to the list. Dr. B. B. Mundkur describes (*Phytopath.*, 28, No. 2, 134, Feb. 1938) a new smut fungus from India. The species is *Urocystis brassicæ*, and although it is somewhat similar to *U. coralloides*, described by Mitra upon mustard, it is described as a new species by reason of its different spore size, and its dissimilar host range. Radish, turnip, cabbage and other related plants are attacked, and the fungus induces galls upon infected roots. The smut is soil borne, and brings about considerable reduction in yield.

Olivine-Fourchites from Antarctica

IN the course of an exploratory expedition from the base camp of the Byrd Antarctic Expedition II, an extinct volcano was discovered in the Raymond Fosdick Mountains. The specimens representing the lava flows, all of which are olivine-fourchite, have formed the subject of a petrological study by C. N. Fenner which is of exceptional interest and significance (*Bull. Geol. Soc. Amer.*, 49, 367–400; 1938). The physical and mineralogical structure of the rocks made possible the separation of the phenocrysts—olivine and pyroxene—from the ground-mass. Analyses of these three products have been made and with the resulting information it has been possible to compare the actual course of crystallization of the magma with what has been deduced from theoretical considerations. The ground-mass has been found to have an ultra-basic composition. This leads to the conclusion that, contrary to inferences reached in the theory of crystal fractionation, wholly liquid magmas of ultra-basic composition can exist. In this connexion it is of interest to note that in a recent presidential address N. L. Bowen has admitted that "difficulties accumulate for him who questions the existence of anchi-monomineralic magmas" (*Am. Min.*, 129; 1938). Fenner has also found that in passing from phenocrystic pyroxene to ground-mass pyroxene, there is decrease of SiO_2 and MgO accompanied by increase of Al_2O_3, iron oxides and CaO. These results do not seem to be in accord with generalizations from experimental work on silicate systems, such as have been used to support the theory of crystallization differentiation. It is pointed out that the final test of conclusions regarding magmas lies in the behaviour and properties of the magmas themselves and of their actual minerals, and that this test should be applied in a more rigorous manner. Inferences from the behaviour of simple laboratory melts should not be generalized to cover conditions to which they may not be applicable.

Phosphors Without Metallic Activator

THE fluorescence of teeth suggests the existence of a type of fluorescent substance different from the more familiar phosphor resulting from firing a salt with a small amount of foreign metal as activator. W. H. Byler (*J. Amer. Chem. Soc.*, 60, 1247; 1938) has prepared phosphors from several inorganic compounds and mixtures without the use of metallic activators, for example, by treating calcium phosphate with phosphoric acid and firing at 400°. Pure basic and acid phosphates of calcium show fluorescent intensities of only 2 and 3 on an arbitrary scale after optimum heat treatment at 400°, but a correct mixture of the two develops an intensity of 10 when similarly treated. Phosphors developed from mixtures of calcium phosphate with certain organic compounds such as tartrates were also studied. Since teeth are made up largely of calcium phosphate in the apatite structure and contain about 1 per cent of organic matter, it is considered that their fluorescence may be due to this type of complex. The general conclusion is reached that, in the absence of a specific metallic activator, fluorescence resulting from heat treatment of inorganic compounds is due to the formation of complexes of critical composition through partial decomposition, or of critical physical condition through modification of crystal structure.

Phenazine Derivatives

A NEW species of bacterium which has been named *Chromobacterium iodinum* isolated at the National Institute for Research in Dairying at Reading produces a violet, copper-glinting pigment outside the organism at the later stages of its growth. This pigment has been examined by G. R. Clemo and H. McIlwain of King's College, Newcastle-upon-Tyne (*J. Chem. Soc.*, 479 ; 1938), and found to be a phenazine derivative of formula $C_{12}H_8O_4N_2$. On reduction, it yielded a compound, $C_{12}H_{10}O_2N_2$, in which two atoms of oxygen in the original compound are replaced by hydrogen. Since no product of biological origin has yet been obtained with a nitro-group (NO_2, which would reduce to NH_2) and the reduction product is readily converted on crystallization to $C_{12}H_8O_2N_2$, the interesting conclusion is reached that the pigment is 1:2-dihydroxyphenazine di-N-oxide, a derivative of the hitherto unknown phenazine di-N-oxide. Other derivatives of this have been prepared, and the synthesis of the purple pigment is to be attempted. The phenazine compounds which have been isolated from natural sources are now three in number, namely, pyocyanine, chloraphine and the present pigment. These are all bacterial pigments, but phenazine compounds have been shown to exhibit biological activity in a variety of organisms and enzyme systems, and it is anticipated that phenazine derivatives will be found much more widely distributed in Nature.

American Steam-Distilled Wood Turpentine

INTER-STATE regulations governing commerce in steam-distilled wood turpentine and gum spirits have emphasized the need for a satisfactory method of distinguishing these two products. Actually they are both derived from the same species of pine, though the former is prepared from stump oleoresin and the latter from fresh gum. Different methods are also employed for their preparation. Even so, continued improvement in the process of refining steam-distilled wood turpentine has made their distinction less and less easy. The United States Department of Agriculture has recently published a Bulletin (No. 596, December 1937) describing a suitable technique for the examination of such products and summarizing the chief differences between steam-distilled wood turpentine and gum spirits discovered by the application of this technique. In short, this process, which consists of systematic fractional distillation, has revealed that the hydrocarbon components of gum spirits consist practically entirely of dicyclic terpenes, whereas those of steam-distilled wood turpentine consist of appreciable proportions of monocyclic terpenes. There is a considerably larger proportion of the dicyclic terpene α-pinene in steam-distilled wood turpentine than in gum spirits. The quantity of β-pinene present in gum spirits is substantial while that in steam-distilled wood turpentine is negligible.

Critical Phenomena in Gases

RECENTLY, three papers by Prof. J. E. Lennard-Jones and A. F. Devonshire have appeared dealing with critical phenomena in terms of interatomic forces (*Proc. Roy. Soc.*, A, **163**, 53 (1937); **165**, (1938); *Physica*, iv, 10, 941 (1937)). An atom in a dense gas is assumed to be confined for the greatest part of its time to a cell, and consequently its average environment closely resembles that of an atom in a liquid or in a crystal. Instead of trying to calculate the properties of such a dense gas from binary encounters, the atom is considered to be subjected continually to multiple encounters. On this basis, by an application of the methods of classical statistical mechanics, an equation of state is derived and values of the critical temperatures of hydrogen, neon, argon and nitrogen are calculated ; these values agree well with those observed. An extension of the method to liquids makes it possible to calculate boiling points in terms of interatomic forces ; those calculated for neon, argon and nitrogen agree well with observed values. In addition, a theoretical interpretation is given to Trouton's rule and to the modified form of it suggested by Hildebrand. Calculations of the vapour pressures and heats of vaporization of the inert gases have also been made.

Wave Mechanics and Stellar Statistics

THIS is the subject of an interesting investigation by Dr. H. Jehle, University College, Southampton (*Z. Astrophys.*, **15**, 182 ; 1938). Jehle deals with the statistics of an assembly of macroscopic mass-points by means of a generalized wave mechanics in ordinary space time. The wave equation differs from Schrödinger's equation only so far as h/mc is replaced by a macroscopic length σ which is characteristic for the assembly in question. Indeed, such a Schrödinger equation can be split into a continuity equation and in a Hamilton-Jacobi equation; and these on the other hand, can be identified with the continuity equation and the Hamilton-Jacobi partial differential equation for the streaming field of a statistical distribution of mass-points. Thus the classical laws of motion are not modified, unlike the case of a single particle in ordinary wave mechanics, but the assumption is introduced that in this assembly the product interval of position times interval of velocity is greater or equal to $\sigma.c$. This is in particular an assumption about the peculiar velocities. This theory has originally been designed for big stellar systems, and it offers an explanation of the following problems : the 180°-symmetry and the very slow development of the structure of spiral nebulæ ; the greatest possible flattening and the average mass density in nebulæ. In the case of the solar system an application of the wave mechanical perturbation theory explains the distribution of the major axes of the planets that is, Bode's law, as well as the exceptions to it (Neptune), and the corresponding distributions in the systems of the moons. The well-known resonance relations between the periods of revolution are given by similar considerations, being in close correspondence to the classical theory of resonance.

The Physical Society

Cambridge Meeting

THE Physical Society has developed the custom of holding at least one of its meetings each session in some centre outside London, and on June 18, through the kindness of Prof. E. V. Appleton, acting director of the Cavendish Laboratory, the meeting was held at Cambridge. About two hundred fellows and their guests attended.

The morning was spent in visits to the Cambridge Press, where Mr. Lewis and his staff did everything possible to make the technical side of printing as clear as possible, or to the Cambridge Field Station of the Radio Research Board, or to the works of the Cambridge Instrument Co., Ltd. Here both the works and the research section were on view, and members and their friends appear to have been particularly impressed by a device for measuring the thickness of sheets of non-magnetic material, which functions without the necessity of access to both sides.

The visitors to the various exhibits assembled at St. John's College for lunch, where the guest of honour was Sir J. J. Thomson. Speeches were short, but the president, Prof. Allan Ferguson, expressed the pleasure of the Society at the presence of Sir Joseph, the sympathy with Cambridge—and corresponding congratulations to Teddington—at the translation of Prof. R. H. Fowler, and a sense of satisfaction with the recognition (by the award of an O.M.) of the work of Sir Arthur Eddington, as well as the sincere thanks of the guests to the Master and fellows of St. John's for allowing them to lunch there. In his reply "J. J." expressed his relief that the finances of the Cavendish Laboratory were no longer his responsibility, and delighted all physicists by the announcement that he has again taken up experimental work there.

The Society devoted the afternoon to a meeting and an inspection of the laboratories, whilst through the kindness of Mr. Barnard, secretary of the Cambridge Antiquarian Society, those whose interests lie outside physics were enabled to enjoy a tour of the colleges, meeting the main party at tea, and thus at any rate seeing one room of the Cavendish Laboratory.

The proceedings at the meeting were opened by Prof. Appleton, who pointed out that one of the main interests of the Laboratory had always been the structure of matter, and mentioned that when Prof. Bragg assumes the professorship in October, he will bring with him the subject which he has built up for himself, and will contribute, from a different aspect, to the studies already in progress there. On the subject of radio research, he explained the frequency modulation method, and showed results obtained on the direct observation of interference fringes in space between the ground wave and the reflected wave. He also dealt with the peculiar fact that, during anomalous periods, the absorption of short waves is diminished at the same time as that of long waves is increased, the explanation being that the increased ionization at these times makes the reflecting layer more perfect for short waves, which are reflected without much penetration, but that long waves are absorbed because they travel farther into the layer. The connexion with sunspots was also expounded, and the problem of why some are associated with high ionization and some are not was mentioned, but left as one of the as yet unsolved problems.

Prof. Appleton was followed by Dr. J. D. Cockcroft, who explained the low-temperature equipment at Cambridge, and described the anomalies of liquid helium II in viscosity and thermal conductivity. He mentioned that the helium liquefier, which functions without pre-cooling with liquid nitrogen, begins to condense helium in about two hours from starting, and then has a yield of about 2 litres per hour. Next he described the cyclotron, and the story of the work on nuclear physics was carried on by Mr. P. I. Dee, who gave an account of some of the more recent work carried out at Cambridge in this fundamental subject.

After the formal meeting, parties were conducted around the Cavendish and Mond Laboratories, where the various research equipment was shown by workers who had generously given up their Saturday afternoon leisure in the general desire to make the visit as pleasant and enjoyable as all the visitors seem to have found it.

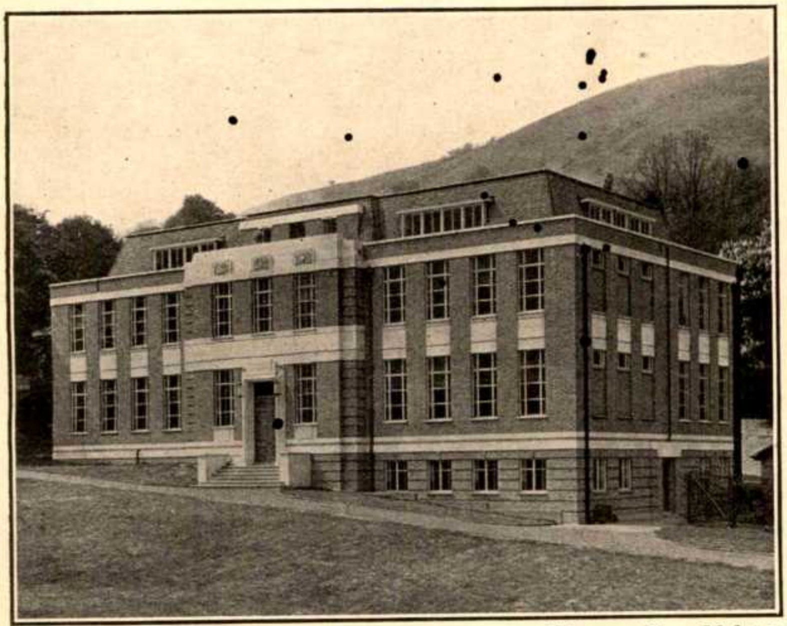
New Science Block at Malvern College

EARL BALDWIN OF BEWDLEY, who has been a member of the Council of the College for many years, opened the new Science Building at Malvern on Saturday, June 18, in the presence of a large company of Old Malvernians, parents and friends of the school. Dr. G. D. Bengough, who left Malvern in 1895, was there, but Malvern's only Nobel prizewinner, Dr. F. W. Aston, was unable to be present.

The building is to be known as the Preston Science School, after the head master, Mr. F. S. Preston, who retired in 1937, at the end of whose tenure of office the building was erected. Before opening the building, Earl Baldwin paid a tribute to Mr. Preston's work at Malvern through twenty-three years, to his high personal qualities and to his breadth of judgment in providing the School with the best equipment available for the teaching of science.

The new building has three floors, which are soundproof. The ground-floor is devoted to the teaching of chemistry, and consists of three teaching laboratories and a large lecture room, capable of seating sixty, together with ample storage space and a laboratory attendant's room. Heating is by radiation from panels concealed in the plaster of the ceiling. Ample fume-cupboards, worked by suction-fans on the roof of the building, are provided. There is a vacuum installation with fourteen points in the different rooms and a hot-water supply to certain sinks.

The advanced chemistry room has desk accommodation for twelve and is to be used both for practical work and for lecturing to small classes of senior boys. There is a glass-working table and a large ventilated combustion-hood, fittings which are also present in the large Fifth Form laboratory. The elementary laboratory has desk accommodation as well as bench space for twenty-four boys. The lecture room has a fume-cupboard, an epidiascope and a fixed mirror-galvanometer with ground-glass scale, the leads being taken to terminals on the lecture bench.



Photo] [*Norman May, Malvern*

PRESTON SCIENCE SCHOOL, MALVERN COLLEGE.

The first floor is intended for the teaching of physics. There are three teaching laboratories, an optical dark room, a photographic dark room which is very fully equipped, a workshop with rectifier plant, a smaller lecture room and a room for storage on this floor. The lecture room has an equipment similar to that of the room on the floor below, except that in addition there is a transformer for supplying an alternating current arc. The advanced laboratory has slate shelves built into the walls for supporting instruments which must be protected from vibration, and a beam is built into the angle of the walls for Young's modulus experiments. All the physics rooms have a variety of benches and tables to which gas, electric light and power are supplied. The surfaces of the tables are free from taps or any other obstruction.

The second floor has four rooms in all, two of which are designed for the teaching of biology. One of them is fully equipped for lecturing and dissection, there being a particularly useful device for washing and cleaning dissecting boards. The other room is arranged primarily for botanical work. These two rooms are connected by a small preparation and store room. A third room on this floor contains four aquaria, a large sink, working benches, drawers, shelves and bookcases ; it is to be used by boys interested in natural history, for arranging, investigating and storing their specimens. The remaining room, which is furnished as a library, contains about six hundred scientific books and many periodicals.

The architects of the building were Messrs. George Hubbard and Son, of 45 New Bond Street, London, and the fittings were designed by Messrs. Munby and Smith, of 9 Old Square, Lincoln's Inn, London.

The Structure of Benzene*

FOR many years attempts were made to explain the peculiarities of aromatic compounds by making various special hypotheses relating to the benzene nucleus. It is a satisfactory feature of the present situation that the theory of benzene is simply a special—and specially important—case of an established general extension of valency theory, and that this extension uses essentially the same physical principles as are applied in the interpretation of valency itself. These are the postulates of the 'new' quantum theory (fundamentally the principle of complementality), which provide at once a physical basis for the forces of valency, and for such departures from the ordinary valency rules as are illustrated so strikingly in the parent of the aromatic series.

From an experimental point of view, we are concerned to establish the correct stereochemical model for benzene, and to discover, also in a quantitative way, as much as possible about the internal forces which maintain that model. Theory creates a predilection for a model of plane, regular hexagonal symmetry, because theory works out most simply if such a model be first assumed. The available experimental methods for the determination of a molecular model are (1) by X-ray or electron interferometry, (2) from rotation-vibration or vibration-electronic spectra. The interferometric method indicates the plane, regular model to a rather close degree of approximation, but the spectroscopic method, which is particularly sensitive, and eminently suitable for application to this problem, was at first claimed to establish a contrary conclusion. For this reason, and also because the spectroscopic method, by giving vibration frequencies, supplies direct information about the internal forces, this method has been recently pursued by Angus, Bailey, Wilson and others; and it has been employed in relation not only to ordinary benzene, but also to benzenes in which a part or the whole of the hydrogen is present in the form of deuterium.

---

* Substance of the Bakerian Lecture to the Royal Society, delivered by Prof. C. K. Ingold, F.R.S., on June 16.

This use of deuterium greatly increases the amount of information obtainable from the spectra; for isotopic substitution leaves the whole force-system of the molecule unchanged, wherefore the vibrations which are responsible for the observed frequencies can be identified by comparing the frequency shifts caused by isotopic substitution with those calculated from the known changes of atomic mass under the assumption of unaltered forces (Teller). Four spectra are studied: Raman scattering, infra-red absorption, ultra-violet fluorescence, and ultra-violet resonance emission. All give information concerning the molecular form and vibrations of the ground state of the molecule. Five benzenes have been examined moderately completely, whilst two others (formulæ in parentheses) are under examination: C_6H_6, C_6H_5D, 1 : 4-$C_6H_4D_2$, 1 : 3 : 5-$C_6H_3D_3$, (1 : 2 : 4 : 5-$C_6H_2D_4$), (C_6HD_5), C_6D_6.

By a comparison of frequency shifts and other spectroscopic characteristics amongst the spectra of these compounds, the frequencies of a large number of vibration-forms have been identified. From this information, with the aid of spectroscopic rules which depend ultimately on a consideration of the physical mechanism of production of the various spectra, it is possible unequivocally to establish the plane, regular model for the isolated (gaseous) benzene molecule. The previously claimed contrary indication is explained as due to the use (or accidental presence) of liquid, wherein the intermolecular forces are sufficient to deform the molecules to a spectroscopically significant extent. An approximate specification of the internal forces could be made at present, but in order to render such a specification complete with respect to harmonic forces, we require further identified frequencies, wherefore the extension involving $C_6H_2D_4$ and C_6HD_5 is necessary.

A Stone Age Rock-Shelter in South Africa

OAKHURST rock-shelter, situated in an enclosed valley on a farm thirteen miles east of the town of George, Cape Province, South Africa, four miles from the Indian Ocean, and two from the coastal lakes, has been excavated by Mr. A. J. H. Goodwin (*Trans. R. Soc. S. Africa*, 25, 3; 1938). Between February 1932 and February 1935, six sits were paid to the cave, varying in duration om a month to a week, during which the excavation was carried out.

The shelter, which is some sixty feet in length and about twenty-five feet deep at surface level, is divided into two parts. Of these, the inner is separated from the outer and southern portion by a hanging buttress of rock. There is a talus on the southern and eastern sides. The inner portion of the shelter has been left undisturbed for future examination. It is anticipated that much richer deposits will be found re, judging from the midden material which had shed out under the buttress. The outer portion been excavated down to the base of the deposits. hese were of considerable thickness, the total depth cavated being one hundred and twenty-six inches.

The shelter is situated in a dense forest, about twenty feet above a stream in a high sandstone overhanging cliff of schistose quartz-bearing sandstone. It is approached by an old elephant path. Nearby were rock paintings in red, partially obliterated and not clear enough to photograph, and game pits.

A large amount of skeletal material was found in the deposits. The bones had been much disturbed y root action; while digging for subsequent interents had frequently interfered with earlier burials. was, therefore, possible to distinguish with rtainty eighteen graves only. There had been many more, but the contents were commingled, and at mes it was difficult to distinguish grave furniture from introduced material. The skeletal remains had also suffered much from the pressure of gravestones. The greater number of burials occurred at a depth of between fifty and sixty inches from the surface, while a space of some seven by five feet included more than half the graves. As the later people buried at a depth of thirty inches, and the earlier at a depth of fifteen inches only, the graves for the most part occurred at approximately the same level.

The major part of the deposits consists of decayed vegetable matter with a high percentage of wood ash. In addition there are vast quantities of shell present throughout the deposit, this in the upper layers constituting a great part of the bulk. Until the deposits had been built up to some height the shelter could not have afforded much protection against the weather. Hence in the early layers there is evidence of temporary occupation only—the remains of one-night fires and burnt bones. With the advent of Smithfield *B* man, occupation takes on a more permanent character. The prevailing stone used by all the occupants of the cave was white quartz, probably from a vein of quartz, one hundred yards away, which has been quarried. Chalcedony and agates were also used, brought from neighbouring beaches.

The uppermost three feet of the deposit consists generally of Wilton material. In the top nine inches only was pottery, below this at a depth of thirty-six inches was a normal Wilton culture, in which stone crescents in white quartz and chalcedony are common. Following this short normal phase (that is, above it), comes a long period in which shell crescents (*Mytilus edulis*), the first shell implements to be described in South Africa, take the place of stone. Apart from this diversion from stone to shell, there is little change, save for the addition of pottery in the latest phase.

Among the ornaments nacre was rare; but vast numbers of ostrich-shell beads were retrieved. In addition there was a single cowrie shell, and a number of naturally bored shells had been brought to the cave, presumably for ornaments. A hippopotamus tusk and one ivory bead were found, as well as borers, arrow points, and tubes of bone. Fish bones, scarce at the beginning of this period, were found in large quantities in later levels, pointing to the development of a considerable competence in fishing. Banked ash at the southern end indicated a protection fireplace, dividing the cave shelter into two compartments, one for general purposes and one for sleeping.

Below the thirty-six inch level Smithfield *C* material extends down to a depth of sixty inches, the richest level being between thirty-six and fifty-four inches. Throughout the deposit only implements of the general scraper type could be recognized with certainty. More than five thousand scrapers in white quartz were collected from the Smithfield deposit. There were as well two hundred flakes of brown chalcedony. The quartz flakes, almost a solid mass, in parts up to two feet in depth, indicated that the shelter at this period must have been a workshop. Throughout this deposit ostrich shell beads in large numbers were found, but nacre ornaments are rare.

At the base of the Smithfield *C* deposit between two buffer layers was a carbon floor or layer, representing a period of peculiarly fierce forest fire, which was presumably the cause of the desertion of the cave by the Smithfield *B* people. The Smithfield *B* culture extended from a depth of sixty inches down to seventy-seven inches or more in parts. It is to be remarked that there is no great difference to be observed between the implements from above and below the carbon floor. The variation is rather one of size, or in distribution of sizes. The scrapers, for example, are much larger. All implements are still of the general scraper family. The deposit as a whole is far less rich than the Smithfield *C* layer and represents the normal debris of a home site. The major part of the material is quartz, chalcedonic quartz being rare and brown chalcedony absent. One end scraper is of fossilized wood from the Tertiary Enon beds. A Mossel Bay point and a Still Bay type mark the overlying deposit as post-dating the "Cape Flats complex".

Below seventy-seven inches evidence of the sterile character of the lower deposits begins to become apparent. In one section a few good Smithfield *B* specimens still appear between the eighty-four and ninety inch levels; but below ninety-six inches formal implements disappear. In the underlying material there are only scattered hearths with burnt bones and quartz split by fire or broken by man, but no implement types that could be recognized. Though there are suggestions of Middle Stone Age technique on some of the flakes, these must be ignored, as deduction from the sugary quartz would be impossible to maintain. There is, however, evidence to show that use was made of the shelter for a very considerable period before Smithfield *B* man appears.

The pottery has been submitted to a careful an detailed analysis by Mr. J. F. Schofield, who term it "Hottentot", and suggests that its specific characters, lugs and an occasional oval section, are a adaptation to the use of the pack-ox by a nomadic people.

The skeletal material has been studied by Prof. M. R. Drennan, whose detailed report deals with the relation of the Oakhurst people to the Wilton race and the Hottentot. The skeletal material shows that these people had many Bushmen characters, but they were of a special type, being much taller and more robust, with bigger heads. They resembled the type to which the term 'Hottentot' has been applied—a term which accordingly has to be define (see Nature, p. 1146). The main conclusion is tha the Boskop type must be regarded as the ancestor of the Hottentot. The infantile material, which is the first series of any extent to be examined sy tematically, has provided data for a study of grow in infancy.

Submarine Light Measurements

At the meeting of the International Council for the Exploration of the Sea held at Copenhagen on May 23–28, a special session was devoted to submarine light measurements. H. H. Poole gave a brief summary of the results obtained by different workers on the variation of surface loss with weather conditions, pointing out the difficulties involved and stressing the importance of further work on the effect of surface conditions on the angular distribution of submarine daylight.

H. Pettersson described the work of himself and his co-workers on the angular distribution at depths of 5 and 10 m. below a smooth water surface. Their measurements showed that, with the sun shining, the illumination was chiefly concentrated within a comparatively small solid angle round the calculated path of a ray of sunlight, as refracted by a smooth surface, the direction of maximum illumination being slightly nearer the vertical at 10 m. than at 5 m. From these results it is possible to calculate the ratio of the total illumination (as measured by a photometer with a spherical receiving surface) to the vertical illumination (as recorded by a plane photometer with its window horizontal). This is important, since the former is the governing factor in photosynthesis, and the latter is usually measured. The values found for the ratio total/vertical ranged from about 1·5 with the sun at 20° altitude to 1·35 with diffuse daylight.

M. Graham described measurements of the opaci of the water at 44 stations in the North Sea made (*a*) the Lowestoft absorption photometer, (*b*) meas ments of the percentage of daylight at a depth 10 m., and (*c*) Secchi's disk. For finding the orig and history of the water masses involved he conside that the use of Secchi's disk has much to recommen it, but that the most promising method is that o Pettersson's transparency meter, in which an artificial light source and a photo-electric cell are used at any required depth.

E. K. Gabrielson and E. Steemann Nielsen reported experiments on the photosynthesis of various diatom in light of different colours. Their results show that for a given amount of energy violet-blue lig produced about twice as great assimilation of car dioxide as either yellow-green or orange-red, the lat spectral regions being about equally efficient.

The special sub-committee on the standardizati of photo-cells for daylight measurements held severa meetings, and hopes soon to be in a position to undertake this standardization in energy units for different spectral regions.

Science News a Century Ago

Beginnings of the Gas Industry

ON June 28, 1838, the chemist Friedrich Christian Accum died in Berlin at the age of sixty-nine years. He was born on March 29, 1769, at Buckeburg, Westphalia. At twenty-four years of age, he came to England and for nearly thirty years made his home at 11 Compton Street, Soho, London. He was well-known as a lecturer, and is remembered to-day for his share in the founding of the gas industry and his books on practical chemistry. He first made a mark with his book on "Theoretical and Practical Chemistry" published in 1803. This was followed by a "Treatise" and a "Manual" on the analysis of minerals, and his book on "Crystallography", of 1823, the first in English based on Haüy's epoch-making work. By this time he had become interested n coal-gas lighting. He carried out some of the earliest experiments for the Gas Light and Coke Company, gave evidence on its behalf before a committee of the House of Commons and in 1812, when the Company was granted its charter, he became one of the directors. He undertook to supply plans and estimates for gasworks, and installed gas-lighting for the Government at the Royal Mint. These occupations led him to write his two books, a "Practical Treatise on Gas-Light" (1815) and a "Description of the Process of Manufacturing Coal-Gas" (1819), both of which were widely read in Great Britain and abroad, contributing much to a general knowledge of the new method of illumination.

Chemistry of Foods

ACCUM was also known for his books on the chemistry of foods published in 1820–21. The first f these was his "Treatise on the Adulterations of ood, and Culinary Poisons", of which 4,000 copies ere sold in a year. On the cover was a representation f a skull and cross bones and the legend, "There is death in the pot. II Kings, c. 4 v. 40", leading to the book being popularly called "Death in the Pot". This was followed in 1821 by a "Treatise on the Art of making good wholesome Bread, etc.", a "Treatise on the Art of Brewing" and "Culinary Chemistry, exhibiting the Scientific Principles of Cookery", probably the first English book of its kind. For some time, Accum was a member of the Royal stitution, the Linnean Society and the Royal Irish ademy, and was well known for his lectures at Surrey Institution, which had been founded in itation of the Royal Institution, for the south of ondon. The Institution occupied the buildings close to the Thames near old Blackfriars Bridge, which once housed the Leverian Museum. The Institution was in existence from about 1806 until 1823, but before it had closed its doors Accum had returned to Germany. In 1820 he was suspected of removing pages from scientific works at the Royal Institution and a search warrant having been obtained he was charged at Bow Street. The magistrate, however, scharged him. The managers of the Royal Institu- n then indicted him before the Westminster sizes. Pleading not guilty, his case was allowed stand over until the next sitting of the court, but cum failed to appear. He had returned to Berlin, where in 1822 he was given a post at the Technical Institute. At Berlin too he published a work in two volumes on the "Properties of Building Materials". Several of his books were published in London by his fellow-countryman, Rudolph Ackermann (1764–1834), whose premises in the Strand, London, were among the first to be lighted throughout by gas.

The Salamander

IN its issue of June 30, 1838, the *Athenæum* had the following note: "M. Paravez has written to the French Academy of Sciences that a fossil Salamander in the collection of Prof. Van Breda, at Leyden, about three feet long, contains in the part corresponding with the abdomen, the fragments of frogs, eels, etc., thereby affording a proof that antediluvean species fed upon the same substances as the Salamanders of our own time. A large Salamander brought by M. Siébold from Japan, still lives in the museum at Leyden, which is principally fed upon frogs. This Salamander is described in a Japanese Encyclopædia, and M. Paravez finds in this work the same fables which exist in Europe concerning the animal, namely, its insensibility to fire. The same stories concerning the chamelion are also found in the Encyclopædia, and bring further conviction to M. Paravez, that a very ancient centre of civilization has existed, whence come the ideas concerning art and science, which have been transmitted to us by the Greeks and Romans, and which are also to be found in Chinese books."

University Events

EDINBURGH.—Prof. J. Bertram Collip, of the Department of Biochemistry in McGill University, Montreal, who was awarded the Cameron Prize for 1937, delivered the prize address on "Results of Recent Studies on Anterior Pituitary Hormones" on June 16.

LEEDS.—At a Congregation to be held on July 4, the following honorary degrees will be conferred, among others: D.Sc. on Prof. Alfred Fowler, emeritus professor of astrophysics in the Imperial College of Science and Technology, and Mr. C. J. T. Cronshaw, managing director, Imperial Chemical Industries (Dyestuffs Group).

MANCHESTER.—Dr. A. R. Todd, of the Lister Institute, and reader in biochemistry in the University of London, has been appointed Sir Samuel Hall professor of chemistry and director of the Chemical Laboratories in succession to Prof. I. M. Heilbron, who is taking up the chair of organic chemistry at the Imperial College of Science and Technology, London.

OXFORD.—In Convocation on June 22, honorary degrees were conferred on the following, among others: D.C.L., Sir James Irvine, vice-chancellor and principal of the University of St. Andrews, Lord Desborough, and Miss Eleanor Rathbone, M.P.; D.Sc., Prof. G. I. Taylor, Yarrow research professor of the Royal Society; D.Litt., Prof. S. A. Cook, regius professor of Hebrew in the University of Cambridge.

Dr. M. Cattle has been appointed tutor in natural sciences at St. Hilda's College.

S. Wylie, New College, research scholar in mathematics in the University of Aberdeen, has been elected to a lectureship (the equivalent of a research fellowship) at Christ Church.

Prof. J. B. S. Haldane has been awarded the Weldon Memorial Prize for 1938.

Societies and Academies

London

Royal Society (*Proc.*, A, 166, 325–449, June 3, 1938).

S. RAMACHANDRA RAO and S. SRIRAMAN : Diamagnetism of cadmium.

C. F. GOODEVE and L. J. WOOD : Photosensitivity of diphenylamine-*p*-diazonium sulphate by the method of photometric curves.

A. J. BRADLEY and A. TAYLOR : An X-ray study of the iron-nickel-aluminium ternary equilibrium diagram.

F. W. JONES and C. SYKES : Atomic rearrangement process in the copper-gold alloy, Cu_3Au (2).

MAX BORN and KLAUS FUCHS : Statistical mechanics of condensing systems.

C. L. SMITH and W. Y. CHANG : An accurate determination of the range-distribution curve of the radioactive α-particles from ^6Li.

HANS MUELLER : On the theory of scattering of light.

Paris

Academy of Sciences, May 2 (*C.R.*, 206, 1273–1332).

V. A. KOSTITZIN : The differential equations of the problem of natural selection in the case of the mutation of a sex chromosome.

FRÉDÉRIC ROGER : The indetermination of analytical functions at their critical points.

HENRI PAILLOUX : The dynamical study of a problem of kinematics.

MAX TEISSIÉ-SOLIER and LOUIS CASTAGNETTO : The determination of the criterion of alternating vortices and the oscillations of relaxation.

JEAN LOUIS DESTOUCHES : The notion of the corpuscle. Application to the heavy electrons.

ERNEST BAUMGARDT : The transparency of solid plates to ultra-sounds. Measurements of the transparency of soft iron disks of different thicknesses to ultra-sounds produced by a quartz emitter lead to a value for Young's modulus agreeing with that determined by the statical method.

PIERRE VERNOTTE : Properties of the Fourier solution in complex systems : application to the distribution of a (heat) flux between bodies in contact.

HENRI BIZETTE and BELLING TSAÏ : The magnetic susceptibility of liquid nitric oxide, NO. The magnetic susceptibility was found to be $3{\cdot}53 \times 10^{-4}$ per cubic centimetre. From this, it is concluded that about 97 per cent of the molecules are polymerized, as against 93 per cent deduced from measurements of the magnetic rotatory power.

THÉODORE KAHAN : The potential barrier in nuclear mechanics and the nuclear dimensions of heavy radioactive bodies.

MARCUS BRUTZCUS : The *a priori* calculation of the calorific powers of hydrocarbons.

ANTONIN ANDANT : The automatic photography of the Raman spectra of liquid mixtures. Application to quantitative determinations. The apparatus described secures that the times of exposure shall be rigorously equal and that the source of light shall remain constant. With this apparatus eight spectra given by the same liquid were absolutely identical.

HENRY CASSAN : The reaction of formation of gas in a producer outside conditions of equilibrium.

MME. JULIETTE GAVORET : The isoelectric point of cellulose. Adsorption and swelling.

HENRI GUÉRIN : Study of the system As_2O_5, BaO, H_2O at 17° C. Characterization of a new barium arsenate, $BaO.2As_2O_5.3H_2O$.

MAURICE GIRARD : The semicarbazone and thiosemicarbazone of *p*-methoxyphenylpyruvic acid. The corresponding dioxytriazine and sulphoxytriazine.

RENÉ JACQUEMAIN and MLLE. GEORGETTE DEVILLERS : Some aminobenzoic esters of ethanediol and propanediol.

PANOS GRAMMATICAKIS : The action of mixed organo-magnesium compounds on the phenylhydrazones of trialkylacetophenones.

MARC BASSIÈRE : The structure of sodium isocyanate. Results of X-ray study of the crystalline salt. The structure is completely analogous with that of sodium nitride (hydrazoate). The arrangement of the atoms of the isocyanic group confirms the formula $O{=}C{=}N{-}$.

MAHMOUD GHALI and ROBERT BUREAU : The proportion of mud in the waters of the Nile, their level and recording at a distance.

PAUL BERTRAND : The successive appearance of the vascular plants and their instantaneous adaptation.

M. and MME. FERNAND MOREAU : New observations on the hormone formation of the perithecia i the Neurospora.

ROGER ULRICH : The comparison of the accumulated lipids in the green pericarps and in the albumen of the seeds of the ivy (*Hedera Helix*).

LOUIS MAUME and JACQUES DULAC : The maintenance of the chemical individuality of the stalk and ear in wheat, at definite physiological stages and in different varieties and media.

MLLE. MARIE THERÈSE FRANÇOIS : The characters of oils from aleurites and their relations with the methods of preparation.

M. and MME. PIERRE ALLORGE : The presence of epiphyllous liverworts in the islands of the Azores.

PAUL ANCEL and PIERRE VINTEMBERGER : The factors of the determinism of bilateral symmetry the egg of *Rana fusca*.

ETIENNE BURNET and JEAN DEBIESSE : T diagnosis of species of the genus *Brucella* by t absorption spectrum of culture broths.

JEAN VIEUCHANGE and MLADEN PAÏC : The actio of ultracentrifugation on the neutralizing antibodie of antivaccinal immunosera.

Amsterdam

Royal Netherlands Academy (*Proc.*, 41, No. 4 ; 1938).

V. S. LUKCHIN: Some generalizations of the problem of infinitely small deformations of rotation rfaces with negative curvature.

B. GAGAEFF: The functions satisfying equations of iptic type.

. G. PINSKER: Analytical representation of some rtially additive functions.

V. ŠMULIAN: The regularly closed and weak ompact entities in a space of the type (B).

D. A. FRANK-KAMENECKIJ: (1) Non-stationary free convection. (2) The temperature distribution in a reaction vessel and the static theory of thermal explosions.

L. A. ARCIMOVIČ and V. A. CHRAMOV: Energy loss of fast electrons by radiation.

L. V. GROŠEV and I. M. FRANK: The probability creation of pairs in krypton by γ-rays.

P. A. REHBINDER and A. A. TRAPEZNIKOV: hanical properties of films and stability of foams.

. A. TRAPEZNIKOV and P. A. REHBINDER: bilizing effect of adsorption layers and their hanical properties.

. V. NIKOLAEV and A. G. ČELIŠČEVA: The thesis of inyoite.

M. N. KALININ: Preparation of esters of the rthosilic acid.

O. E. ZVIAGINCEV and E. L. PISARŽEVSKAIA: The action of sulphide minerals on solutions of gold chloride and cyanide.

N. A. IZGARYŠEV and E. S. SARKISOV: Mutual displacement of metals from vapours of their salts and the application of this process in the prevention of corrosion.

N. NEKRASOV: The non-equilibrium oxidation-reduction potential.

P. L. BEZRUKOV: Lower Silurian geosynclinal phosphorites in the north-eastern branch of the Karatau Range.

A. E. FERSMAN: The tetrahedral structure of minerals.

N. A. SKOPINCEV: Organic matter in sea-water and foam in the south-eastern part of the Caspian Sea (October–November 1936).

DONTCHO KOSTOFF: (1) Studies on polyploid plants (18). Cytogenetic studies on *Nicotiana sylvestris* × *N. tomentosiformis* hybrids and amphidiploids, and their bearing on the problem of origin of *N. tabacum*. (2) Heterochromatic (inert) region in chromosomes of *Crepis capillaris*.

A. I. ZHURBIN: Comparative study of cell sizes of auto- and allopolyploids.

E. I. HARETSCHKO-SAWITZKAJA: A method for obtaining seeds in self-fertilization of autosterile varieties of *Beta vulgaris*.

A. I. POTAPOV: Soil reactions in the forests of Lenkoran and western Georgia from the point of view of citrus and tea cultivation.

C. S. AFANASIEV: A new valuable rubber plant (*Scorzonera kirgisorum* sp. n.) from the Pamiro-Alai.

D. K. TRETYAKOV: (1) External canaliculi of the lateral line of fishes. (2) Seismosensory canals in the flying fish.

A. A. WOITKEWITSCH: Morphogenetic activity of the various parts of the hypophysis.

R. J. KOVDA and A. A. WOITKEWITSCH: Biological action of an ultra-high frequency electric field.

B. NOVIKOV: Sex hormone and characters of partial monomorphism in *Perdix perdix* L.

A. M. VASIUTOČKIN: (1) The degeneration of seminal tubules. (2) Regeneration phenomena in frog intestine.

Washington, D.C.

National Academy of Sciences (*Proc.*, 24, 165–198; April 15, 1938).

G. A. LEBEDEFF: Intersexuality in *Drosophila virilis* and its bearing on sex determination. Genetical and morphological investigation of some intersexes, which are morphologically hermaphrodites of all grades, indicates that they start to develop as females, but after the 'turning point', any imaginal disks which differentiate become male organs. The time at which the 'turning point' occurs determines the degree of maleness or femaleness of the adult hermaphrodite. Applying these results to normal sex determination, it is suggested that sex is determined by the balance between the gene for femaleness (in the X-chromosome) and that for maleness (in the third chromosome), the balance being maintained by suppressors controlled by the XY mechanism.

S. HECHT and E. G. PICKELS: Sedimentation constant of visual purple. Frog's visual purple was examined in an air-driven ultracentrifuge (160,000 times gravity). The single sedimentation boundary was photographed with both the blue and the green radiation from mercury, and gave experimentally the same value for the sedimentation constant. This indicates that the asymmetry of the absorption curve is an integral property of the visual purple. Bleached visual purple gave the same constant, showing that bleaching does not cause drastic splitting of the molecule. The molecular weight is probably about 270,000 and the molecule itself not quite spherical.

B. H. WILLIER, MARY E. RAWLES and F. C. KOCH : Biological differences in the action of synthetic male hormones on the differentiation of sex in the chick embryo. The hormones were injected into eggs incubated for 43–72 hours. Androsterone and dehydroandrosterone are more toxic than testosterone propionate ; the former have both masculinizing and feminizing effects, whereas the latter has a masculinizing effect only on differentiating gonads and gonoducts.

F. D. MURNAGHAN : (1) The generalized Clebsch-Gordan formula. (2) Analysis of representations of the real orthogonal group.

A. L. FOSTER : Natural systems.

H. M. MACNEILLE : Extensions of measure.

R. OLDENBURGER : Representation and equivalence of forms.

Forthcoming Events

Tuesday, June 28

NATIONAL PHYSICAL LABORATORY, at 2.30.—Annual Inspection by the General Board.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 9.—H. J. Braunholtz : "Ethnographical Museums and the Collector : Aims and Methods" (Presidential Address).

Thursday, June 30

ROYAL SOCIETY, at 4.30.—Prof. A. N. Richards : "Processes of Urine Formation" (Croonian Lecture).

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.

JUNIOR SCIENTIFIC OFFICER at the Building Research Station, Watford—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (June 27—quote ref. *J.* 38/6).

PRINCIPAL of Wakefield Technical College—The Director of Education, 27 King Street, Wakefield (June 27).

LECTURER IN BOTANY in Bedford College for Women, Regent's Park, London, N.W.1—The Secretary (July 1).

LECTURER IN ELECTRICAL ENGINEERING in the Brighton Technical College—The Education Officer, Education Offices, 54 Old Steine, Brighton, 1 (July 1).

LECTURER IN MECHANICAL ENGINEERING in the School of Engineering, Khartoum—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1 (July 1).

ASSISTANT LECTURER IN MECHANICAL ENGINEERING in the Manchester Municipal College of Technology—The Principal (July 4)

DEMONSTRATOR IN PHYSIOLOGY and DEMONSTRATOR IN PHYSICS in the London (Royal Free Hospital) School of Medicine for Women—The Warden, 8 Hunter Street, W.C.1 (July 8)

DEMONSTRATOR IN BOTANY in the University of Birmingham—The Secretary (July 9).

CHEMIST in the Department of the Government Chemist—The Government Chemist, Clement's Inn Passage, Strand, W.C.2 (July 9).

IRWIN PROFESSOR OF AGRICULTURE in the Benares Hindu University—The Pro-Vice-Chancellor (July 15).

LECTURER IN ANATOMY in the University of Aberdeen—The Secretary (July 15).

DEMONSTRATOR IN PHYSICS in King's College, Newcastle-upon-Tyne—The Registrar (July 16).

GOLDSMID PROFESSOR OF MATHEMATICS in University College, London—The Academic Registrar, University of London, Senate House, W.C.1 (July 29).

SECRETARY of the Institution of Professional Civil Servants—The Hon. Secretary, I P C.S , 69 Victoria Street, London, S.W.1 (July 30).

SCIENTIFIC OFFICER under the Water Pollution Research Board—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (July 4—quote ref. *J.* 38/7).

ASSISTANTS (grade III) in the Meteorological Office—The Secretary (S.2.a.), Air Ministry, Adastral House, Kingsway, W.C.2.
